The whole stock of a poor Arabian of the desert consisted of a beautiful mare; this the French Consul at Said offered to purchase, with an intention to send her to Louis the fourteenth. The Arab, pressed by want, hesitated a long time, but at length consented, on condition of receiving a very considerable sum of money, which he named. The Consul wrote to France for permission to close the bargain, and having obtained it, sent immediately to the Arab the information.

The man, so poor as to possess only a miserable rag, a covering for his body, arrived with his magnificent courser. He dismounted, and looking first at the gold, and then steadfastly at his mare, heaved a deep sigh:—"To whom is it (he exclaimed) that I am going to yield thee up? To Europeans! who will tie thee close, who will beat thee, who will render thee miserable! Return with me, my beauty, my jewel! and rejoice the hearts of my children!" As he pronounced the last words, he sprang upon her back, and was out of sight almost in a moment.

The Arabian horses are in general less in stature than our own, being not above fourteen, or fourteen hands and a half, high. Still, however, they must be considered as the first and finest breed in the world; and that from which all others have derived their principal qualifications. It is even probable that Arabia is the original country of horses; since there, instead of crossing the breed, they take precaution to keep it entire. In other countries they must continually change the races, or their horses would soon degenerate; but there the same blood has passed down through a long succession, without any diminution either of force or beauty.

The race of Arabian horses has spread itself into Barbary, among the Moors, and has even extended across that extensive continent to the Western shores of Africa.

Among the Negros of Gambia and Senegal, the chiefs of the country are possessed of horses, which, though little, are very beautiful, and extremely manageable. Instead of barley, they are fed in those countries with maize, bruised and reduced into meal, and mixed up with milk when they design to fatten them. These are considered as next to the Arabian horses, both for swiftness and beauty; but they are still rather smaller than the former.

The Arabian breed has been diffused

into Egypt as well as Barbary, and into Persia also. The horses of these countries a good deal resemble each other. They are usually of a slender make; their legs fine, bony, and far apart; a thin mane, a fine crest; a beautiful head; the ear small and well pointed; the shoulder thin; the side rounded, without any unsightly prominence; the croup is a little of the longest, and the tail is generally set high.

Next to the Barb, travellers generally rank the Spanish genetie. These horses, like the former, are little, but extremely swift and beautiful. The head is something of the largest; the mane thick; the ears long, but well pointed; the eyes filled with fire; the shoulder thickish, and the breast full and large. The croup round and large; the legs beautiful, and without hair; the pastern a little of the longest, as in the barb, and the hoof rather too high. Nevertheless, they move with great ease, and carry themselves extremely well. Their most usual colour is black, or a dark bay.

The Italian horses were once more beautiful than they are at present, for they have greatly neglected the breed. Nevertheless, there are still found some beautiful horses among them, particularly among the Neapolitans, who chiefly use them for the draught. In general, they have large heads and thick necks. They are also restive, and consequently unmanageable. These faults, however, are recompensed by the largeness of their size, by their spirit, and the beauty of their motions. They are excellent for show, and have a peculiar aptitude to prance.

The Danish horses are of such an excellent size, and so strong a make, that they are preferred to all others for the draught. There are some of them perfectly well shaped; but this is but seldom seen, for in general they are found to have a thick neck, heavy shoulders, long and hollow back, and a narrow croup: however, they all move well, and are found excellent both for parade and war. They are of all colours, and often of whimsical ones, some being streaked like the tiger, or mottled like the leopard.

The German horses are originally from Arabian and Barbary stocks; nevertheless, they appear to be small and ill shaped: it is said also, that they are weak and washy. The Hungarian horses, on the other hand, are excellent for the draught as well as saddle.

The Dutch breed is good for the

draught, and is generally used for that purpose over all Europe; the best come from the province of Friezeland. The Flanders horses are much inferior to the former; they have most commonly large heads, flat feet, and swollen legs; which are essential blemishes in horses of this kind. The French horses are of various kinds; but they have few that are good. The best horses of that country come from Limosin: they have strong resemblance to the Barb, and, like them, are excellent for the saddle; but they are slow in coming to perfection: they are to be carefully treated while young, and must not be backed till they are four years old. Normandy furnishes the next best; which, though not so good for the road, are yet better for war. In general, the French horses have the fault of being heavy shouldered, which is opposite to the fault of the Barb, which is too thin in the shoulder, and is, consequently, apt to be shoulder-slipped. The French have lately imported many stallions and brood mares from England.

It has not been without great assiduity, and unceasing application, that the English horses are now become superior to those of any other part of the world, for size, strength, swiftness, and beauty. It was not without great attention, and repeated trials of all the best horses in different parts of the world, that we have been thus successful in improving the breed of this animal: so that the English horses are now capable of performing what no others could ever attain to. By a judicious mixture of several kinds, by the happy difference of our soils, and by our superior skill and management, we have brought this animal to its highest perfection. An English horse, therefore, is now well known to excel the Arabian in size and swiftness, to be more durable than the Barb, and more hardy than the Persian. An ordinary racer is known to go a mile in two minutes; and we had one instance, in the admirable Childers, of still greater rapidity. He has been frequently known to move above eighty-two feet and a half in a second, or almost a mile in a minute: and no horses can any way equal our own, either in point of beauty, swiftness or strength.

**HORSE-BALLS.** Masses of medicine, of the consistence of dough, which are passed down into the stomach of a horse for the cure of his diseases.

**HORSEMANSHIP.** The art of riding safely and gracefully on horseback.

We shall present the reader with a few useful hints from Mr. Hughes's *Treatise on Horsemanship*.

“ If you would mount with ease and safety, stand rather before the stirrup than behind it; then, with the left hand, take the bridle short, and the mane together, help yourself into the stirrup with your right, so that, in mounting, your toe does not touch the horse. Your foot being in the stirrup, raise yourself till you face the side of the horse, and look directly across the saddle; then, with your right hand, lay hold of the hinder part of the saddle, and, with your left, lift yourself into it.

On getting off the horse's back, hold the bridle and mane in the same manner as when you mounted, hold the pommel of the saddle with your right hand, to raise yourself; bring your right leg over the horse's back, and let your right hand hold the hind part of the saddle, and rest a moment on your stirrup, just as when you mounted. But beware that, in dismounting, you bend not your right knee, lest the horse should be touched by the spur. Grasp the reins with your hand, putting your little finger between them. Your hand must be perpendicular, your thumb uppermost upon the bridle.

Suffer him not to finger the reins (the groom, in holding the horse), but only to meddle with that part of the head-stall which comes down the horse's cheek: to hold a horse by the curb, when he is to stand still, is very wrong, because it puts him to needless pain.

When you are troubled with a horse that is vicious, which stops short, or, by rising or kicking, endeavours to throw you off, you must not bend your body forward, as is commonly practised in such cases; because that motion throws the breech backward, and moves you from your fork or twist, and casts you out of your seat: but the right way to keep your seat, or to recover it when lost, is, to advance the lower part of your body, and to bend back your shoulders and upper part. In flying or standing leaps, a horseman's best security is the bending back of the body.

The rising of the horse does not affect the rider's seat; he is chiefly to guard against the lash of the animal's hind legs, which is best done by inclining the body backward. Observe farther, that your legs and thighs are not to be stiffened, and, as it were, braced up; but your loins and body should be lax and pliable,

like the coachman's on his box. By sitting thus loosely, every rough motion of the horse will be eluded ; but the usual method of fixing the knees only serves, in great shocks, to assist the violence of the fall. To save yourself from being hurt, in this case, you must yield a little to the horse's motion ; by which means you will recover your seat, when an unskilful horseman would be dismounted.

Take, likewise, particular care not to stretch out your legs before you ; because, in so doing, you are pushed on the back of the saddle : nor must you gather up your knees, as if riding upon a pack, for then your thighs are thrown upwards. Let your legs hang perpendicularly, and sit on the thickest part of your thighs, but let them bear inward, that your knees and toes may incline inwards likewise. If you find your thighs are thrown upwards, open your knees, whereby your fork will come lower on the horse. Let the hollow or inner part of the thighs grasp the saddle, yet so as to keep your body in a right poise. Let your heels hang straight down ; for, while your heels are in this position, there is no danger of falling."

The following is an excellent rule :—  
"If your horse grows unruly, take the reins separately one in each hand, put your arms forward, and hold him short, but pull him not hard with your arms low ; for, by lowering his head, he has the more liberty to throw out his heels : but if you raise his head as high as you can, this will prevent him from rising before or behind ; nor, while his head is in this position, can he make either of these motions.

Is it not reasonable to imagine, that, if a horse is forced towards a carriage which he has started at, he will think he is obliged to attack or run against it ? Can it be imagined that the rider's spurring him on, with his face directly to it, he should understand as a sign to pass it ? These rational queries are submitted to the serious consideration of such as are fond of always obliging their horses to touch those objects at which they are, or affect to be, frightened." See HACK.

There is a circumspection to be adopted advantageously by the unskilful, which will, at first, give them the semblance, and afterwards the reality, of good riding. The method of taking a rein in each hand occasionally (much in use of late years) gives the rider great command over the mouth, neck, and fore-quarters, of a horse.

A good horseman, without pressing too

much upon the mouth of his horse, is always prepared to assist him, in case of a blunder, with the united exertions of his arm, chest, shoulders, and loins ; and, from the force of constant habit, this comes instinctively, as it were, for the occasion, even if the accident be unnoticed, or the mind otherwise engaged. Both hands upon the bridle are necessary and becoming, in riding fast down steep descents or stony ways ; and it is extreme folly to commit the reins to the neck even of the safest horse.

Some speedy and jadish horses will, after they have got their provender, on being travelled briskly thirty or forty miles, at the next stage fall into a slow trot, bend their necks, foam at the mouth, refuse to bear at all upon the bit, and keep perpetually upon the curvet, as if they longed to be upon the parade. Whenever this happens, the best way of concluding the business is to walk them the remainder of the journey, and then give them a week's rest.

Previous to mounting, every gentleman will find his account in examining both horse and furniture with his own eyes and hands ; for, however good and careful his groom may generally be, it is a maxim, that too much ought not to be expected from the head of him who labours with his hands. Besides, all such sedulously avoid trouble, particularly in nice matters. For example, see that your curb is right, that your reins are not twisted, that your girths, one over the other, still bear exactly alike ; that the pad be not wrinkled up ; but, above all, that your saddle lies exactly level upon the horse's back. Mr. Lawrence says, he has known capital grooms, in the service of sporting gentlemen, so careless in placing a saddle, that it has absolutely worn awry, and would never sit even afterwards.

In journey-riding, every person ought to know, that no great performances are to be expected from a hack which is not in thorough condition. If he has been lately from grass or straw-yard, or has been kept within upon the saving plan of abridging his food in proportion to his work (a favourite measure with some people), he will receive injuries from a long journey, however good he may be in nature. In such case, from thirty to five-and-forty miles is a sufficient day's work.

On the subject of *female equitation*, or ladies riding on horseback, a quotation from Mr. Hughes will be acceptable. He

describes, as most proper, the following method of mounting.

“ A person should stand before the head of the horse, holding with each hand the upper part of the cheek of the bridle. Then the lady must lay her right hand on the near side of the pommel, and her left hand on the left shoulder of a gentleman (or a servant), who will place both his hands together, the fingers and thumbs being interwoven with each other. This being done, let the lady put her left foot on the gentleman's hands, and, giving a little spring, she will be vaulted into the saddle in a moment. When she is thus seated, let her rest the ball of her left foot firm in the stirrup; and, to prevent accidents, she should wear Italian shoes, with very long quarters, and the heel of the shoe coming forward to the middle of the foot. Ladies' shoes made in the common fashion are dangerous, because the foot rests in the hollow between the toes and the heel. Remember that the pommel of the saddle should be made very low, that the lady's knee may not be thrown too high, and the stirrup should hang low; both which circumstances will help to give her a graceful figure, and add greatly to those charms which nature has bestowed on her. When she is thus placed, let her take her whip in her right hand, near the head, with her thumb upon it, and the four fingers under it, holding it obliquely, so that the small end of it may be some inches above the middle of the horse's hind-leg. The arm that supports the whip is always to hang straight, but with a kind of negligent ease: nothing looks more awkward than a lady's holding the whip with her arm crooked at the elbow. A lady should hold her bridle moderately slack, with her little finger under the reins, and the next two fingers passing between the reins, on the top of which her thumb must be placed. Being thus seated, she will either walk her horse off gently, or put him into his other paces at her pleasure.

The pommel of a lady's saddle should be always made with a turn-again screw, to take off, in case the rain, wind, or sun, are troublesome, when a lady may ride on the contrary side of the horse.”

The great secret of riding is to be able on all occasions to take a corresponding motion to that of the animal who carries you.

*Riding to hounds.*—There are few, if any, works in existence, which contain more sound sense, and plain reasoning,

than Adams's Horsemanship; he was a great master both of the science and practice of riding; and his ideas on the subject (with trifling exception) are so clearly expressed, that his meaning can never be misunderstood. If I were disposed to find fault with what Adams has said on the subject of riding, I should say that his mode of instruction was perhaps a little trifle too much *à la militaire*, which, however well it may be calculated for the purpose of pomp and parade, is by no means suited to the sportsman; and, indeed, it is tolerably evident, that though a most accomplished horseman, either in the school, on the parade, or on the road, he had seldom, if ever, followed the hounds. If other proof were wanting of Adams's ignorance on the subject of hunting, abundant evidence is given in his Appendix, p. 181, where he gravely talks of a *horse hunting three times a week!* I make no doubt, that Adams would have ridden well to hounds; but not till after some little practice; though it must be admitted, that riding masters, generally speaking, are but indifferent workmen over a country. The same remark will apply, perhaps in a still greater degree, to those persons, who in circuses and similar places, cut such extraordinary capers, and astonish the gaping crowd by feats of dexterity on horseback.—The celebrated Makeen, who, in his day, arrived at the very pinnacle of his profession as a circus rider, appeared, when following the hounds, completely out of his element; and, across a country, was not only a bad, but a very timid, rider: this I assert, not upon report, but from ocular demonstration; indeed I have, at various times, seen several other professional riders in the field; but never met with one that rode well or boldly over a country. At the first blush of the case, this may seem strange; but it is, nevertheless, easily accounted for; or, in other words, the problem admits of an easy and satisfactory solution. In the first place, the riding of all these professors is so regulated by rule and method, and the horses so completely drilled for the purpose, that it becomes, as it were, mechanical; while riding after hounds, on the contrary, is not susceptible of that systematic order, which constitutes the very perfection of the school; and, therefore, a professor of riding, from whom much is expected, makes but a poor figure after hounds, unless by practice, he render himself a workman. But it would seem

that riding masters are not fond of hunting; they are seldom seen in the field; and I never yet observed one there who appeared to advantage. Further, I have met with riding masters, who were able to give the best possible instructions for the management of the horse, and who, when the animal was put over the bar, would not fail to mark the slightest disorder in the rider, but who, nevertheless, avoided, if possible, riding the horse over the bar themselves. Hence it may be easily perceived that the present article was indispensable, in order to render the article on horsemanship as complete as possible.

While on this subject, it may not be amiss also to notice, that the military style of riding is by no means well adapted for following hounds. The military style has been uncommonly well described by Adams: in this place, it can be only requisite merely to observe, that it may look very well in soldiers, may be admirably calculated for military purposes, for aught I know to the contrary; but the straightness of the knee, and the stiffness of the leg and thigh, together with the toe merely stuck in the stirrup, circumstances so characteristic of the present military style of riding, are completely and absolutely at variance with the method of riding across a country, as far as regards safety and ease, and indeed as far as regards every thing else desirable in following hounds. I have certainly seen military gentlemen riding in their own style after hounds; but I never thought it looked well; in my estimation, it had not a sportsman-like appearance; and, what is worse than all—it is not safe. This reminds me of the fate of Lord Arthur Paget. This gallant young Nobleman belonged to the 10th Hussars, a party of whom were lying in York in the year 1825. In the month of November of that year, I met the York and Ainsty fox hounds at Skelton Springs, where I saw Lord Arthur Paget, and several other officers of the same corps to which he belonged. They rode in the military style. A few days afterwards, Lord Arthur Paget was killed by a fall from his horse while hunting either with the same hounds or with a neighbouring pack. I was not present when the accident happened; but from the account I received of the affair from a brother sportsman, I have reason to believe he would not have lost his life, had he ridden in the correct hunting style—with stirrups short rather than long, and the feet home in them.

The great secret, or the very essence, I may say, of the art of riding, consists (as indeed Adams has slightly noticed) in assuming or taking a corresponding motion to that of the horse; or, in other words, the rider should accommodate himself, with a pleasant pliability to every motion of the horse: whenever it is otherwise, his seat will be unpleasant, unsafe, and indeed dangerous. This may be regarded, not only as the essence of horsemanship (as I have already observed) but as the fundamental principle, from which subsequent excellence or proficiency must arise; and cannot be too deeply impressed on the minds of those who feel any interest in the subject. On this account, I would advise those who wish to become excellent horsemen to practise without stirrups, which they will find of the greatest possible service in forming a *close* secure seat. Respecting the *close* seat, it may not be amiss here to remark, that there are to be found advocates for the *loose* seat. On this subject, I had, some few years ago, a conversation with a riding master, who seemed to think that a *loose* seat in hunting was to be preferred: on expressing my surprise at such a notion, he endeavoured to prove the correctness of his position by observing, that, in case of a fall, the horse would not be so likely to roll on the rider, as the latter would most probably be thrown several yards from him. The man who reasoned thus is a good rider in the school, and has an elegant seat on horseback; but, like some others of his fraternity whom I have met with, he is timid; and his remarks on this subject were evidently the offspring of fear rather than philosophy; nor, when duly considered, can any thing be more remote from truth. Admitting that a loose seat will be the cause of precipitating the rider to a distance in case of the horse falling, the very circumstance itself appears to me more pregnant with danger than the chance of the horse rolling upon his rider. The most imminent danger, I conceive, of a horse rolling upon his rider, is when, in jumping timber, a wall, or other fence with a stiff top, the horse catches it with his fore feet, and goes "*bull-neck over*," to use a very expressive phrase of a sporting friend; and I am in doubt whether in this case the loose rider is not in more danger than the close rider. At all events, a loose rider must calculate on a great number of falls, since, with a seat of this description, he must be liable to be unhorsed on every trifling irregularity, cir-

cumstances which are constantly occurring, in following hounds across a country.

But it does not always happen, that a horse comes "*bull-neck over*," if he tips the top of a gate or style; since one which I at present possess, a good hunter too, and has carried me many times after hounds, has frequently carried off the top bar of a gate, but kept his legs, nevertheless; indeed such a circumstance, when a strong horse comes thus in contact with a weak or rotten gate or rail, is sure to happen.

In advising a young sportsman to practice riding without stirrups, it must not be understood, that I consider the stirrups as useless: on the contrary, the ease of the sportsman depends mainly upon them, and frequently his safety also. I am aware that riding masters pretend (and Adams among the rest) that the use of the stirrup adds no security to the seat; but, if they mean to apply this maxim to riding after hounds, it is not only untrue, but a positive absurdity. The knee and the calf of the leg are the main holds of the horseman in riding over fences, and, indeed, in riding over a country in general, and these cannot be applied with half their embracing force to the sides of the horse, without the use of the stirrups: the experiment is easily made; and those who choose to take the trouble of making it will not only perceive the evident utility of the stirrup, but be fully convinced, that a short stirrup rather than a long one, and the foot home in it, is, of all positions, that which enables the rider to embrace his horse most firmly, and consequently is the most conducive to his safety.

In speaking of *short stirrups*, it will be necessary to define more particularly what I mean by the term; and this I will endeavour to do, in language sufficiently clear, so as to avoid, or prevent, even the possibility of misconception. The seat upon horseback may be compared to the seat upon a common chair; and, therefore, for hunting, I would have the stirrup of that precise length as would allow the rider to sit fairly upon the saddle: if, for instance, it be taken up so short that it pushes or removes the rider towards the cantle of the saddle (which he will easily perceive on trying the experiment) it is then too short; but, while the rider can sit fairly down in the saddle, I am of opinion the stirrup cannot be too short.

Moreover, in regard to the stirrup, I am by no means convinced that Adams

is correct in recommending the heel to be sunk lower than the toe: such a position may appear more elegant in the school, on the parade, or on the road (since fashion renders forms elegant at one period which at another would be considered completely *outré*); but I have no hesitation in saying, that it is not the true position for hunting: in jumping, for instance, it is out of the question, the toe rather than the heel will be necessarily sunk; and, as far as relates to the closeness of the seat, and the security of the rider, a person need only make the experiment once to be perfectly convinced, that, with the heel sunk, he loosens the grip, or embracing power of the knee, and of the calf of the leg, particularly of the latter: let him reverse the position of the foot in some degree, and then judge for himself.

Contrary to the maxims of riding masters, I am decidedly of opinion, that the muscles of the thighs are capable of very little adhesive or compressive force, and consequently the rider must necessarily depend for security upon the knee and calf of the leg (preserving always the balance of the body) which, as I have already observed, he will find very materially assisted by a short stirrup. Moreover, the firm grasp of the calf of the leg loosens, in some trifling degree, the gripe or pressure of the thigh to the saddle; and, after all, the young sportsman may rest assured, that nothing can hold him so closely to the saddle, so firmly, or so securely, as the adhesive gripe of the knees and calves of the legs, when jumping.

The instructions of riding masters are to keep the body erect, with the shoulders well back, and the chest thrown out: as general directions, these are correct enough; but, as in hunting, so many incidental or unforeseen circumstances occur, these instructions, though kept in mind, must be made subservient accordingly. Therefore, upon the incidental irregularities which occur in hunting, I must once more observe, that the rider must make his motions correspond with those of the horse, and by keeping this maxim steadily in view, he will seldom be at a loss. It sometimes happens that a steep bank opposes the sportsman's progress, which it is not possible to jump (and banks indeed present very frequently, awkward jumps, even when jumping is practicable) but every perfect hunter will make his way over such places, and the rider must suit himself to the motion accordingly.

Having made the preceding remarks, the management of the bridle would appear the next object of consideration; and much more depends upon this, than a superficial observer would be induced to suppose—in fact, it may be said that the finishing excellence of a horseman is the skilful management of the bridle. Adams particularly notices the circumstance, that grooms are generally very deficient in this respect, and I have received ocular demonstration of the truth of his remark many scores of times. The fact is, grooms are drilled to riding from mere practise; many of them cannot read, and those that possess some trifling knowledge of English, are seldom inclined to exercise it in perusing what has been written on the science of Horsemanship—they never study riding as a science; and hence, though some of them appear to ride well, they are unable to describe the true principles of what may, in some degree, be called their own profession. I have repeatedly witnessed falls, in jumping, from the awkwardness in which the groom has managed the reins; and, even in huntsmen and whippers-in, I have occasionally witnessed something of this sort. Sebright, (hunter to Lord Fitzwilliam) is perhaps as good a rider as any huntsman or groom in the kingdom, and yet I have frequently thought he *wanted a finger*—indeed, I am not aware that I ever met with an ignorant man that was any thing like perfect in this respect. If it be allowed that huntsmen and whippers-in generally ride well, it must, at the same time, be admitted, that they have heavy hands, or, in other words, that they have no idea of the delicate and scientific management of the bridle.—Shaw, that for some years hunted the Duke of Rutland's fox-hounds with great éclat, was perhaps an exception. Shaw was a very superior man in his station, and I consider him as good a huntsman as ever fell under my observation.

It is, beyond all question, the heaviness of the rider's hand that renders the horse's mouth hard or insensible; but it is certainly a defect not very difficult to remedy; for, as a horse very soon accommodates himself, or his mouth, to a heavy handed rider, so also is he easily brought, by proper management, to ride as lightly and as pleasantly as possible. I am of opinion that a horse's mouth cannot be too delicate; though I am perfectly aware, that there are those that think otherwise; and it is common enough for unreflecting

sportsmen to remark, in opposition to this, that they like a horse, in hunting, to pull a little: the truth is, that all horses, if they are good for any thing as hunters, pull sufficiently hard in the eagerness of pursuit, and it therefore does not follow because a horse is very obedient to the bridle, that he does not therefore pull sufficiently hard when he is following the hounds; since, when he is extended in the gallop, he must take a support from the hand.

What is called *Lifting* horses at their leaps or jumps is a matter which does not appear well understood; or, at least, is frequently practised very disadvantageously. Lifting a horse at his leaps, if he is to be lifted at all, is an operation which requires skilful, delicate, and dextrous management; and if it be not thus managed, it must always be injurious in its applications, and sometimes disastrous. The intention of lifting horses at their jumps is to assist them; and in order to arrive at a correct notion of the manner in which this operation can be applied to advantage, we must, in the first place, endeavour to take a view of the form and manner in which a horse prepares for and accomplishes the object. It appears to me that the manner in which a horse prepares himself for a leap, or in more modern phraseology, for a jump, may not be unaptly compared to the bending of a bow—the jump of a horse is a propelling spring, performed principally by the elastic power of the tendons, in which, however, the muscles materially assist; and in order to accomplish a jump, the horse compresses or draws himself together, and by the elastic force which he thus acquires, he is enabled to propel himself to certain heights and certain distances, which are denominated jumps or leaps. If we observe a horse at large, in the field, without any rider, preparing for a jump, preparing for instance, to jump out of his own paddock into another, we shall perceive that he lowers his head (particularly if a standing jump) immediately before he takes the spring, as if to give greater force or effect to the following motion: hence, it is very fair to conclude, that this is the natural and best mode for a horse to prepare for the spring: even when mounted, a horse will prepare himself precisely in the same way, unless controlled by his rider; though it must be admitted that this lowering of the horse's head is much more perceptible in the standing leap than in the flying leap; but it certainly

takes place in each. It follows, consequently, if the horse is to be lifted, that the utmost care should be taken not, in the least, to retard, or rather to obstruct, his natural motions, since his elastic force or spring must be weakened or reduced, in precise proportion to the force of the obstruction interposed. Hence we may easily perceive, that the utmost delicacy of the finger or hand is amply sufficient for the business in question, and if the mouth of the horse be merely felt by the finger, that is as much force as, generally speaking, ought to be applied till the horse has fairly taken his spring; but when the horse is descending, as it were, the feel of the finger or hand should be increased, and indeed continue increasing, till he has fairly landed; and by this means the horse lands, or comes to the ground, more safely and more pleasantly both to the rider and to himself. Many excellent sportsmen I have seen go at their jumps with as loose a head or rein as possible, and this, after all, is the best way. It is true, when a horse has been long accustomed to be ridden at his leaps in a different manner, and performs well, it may be advisable to continue to ride him in the same way, or at least to alter the system gradually. Further, when, in the length of the chase, a horse has become excessively fatigued, he will naturally want a much greater support from the hand, even to keep him from falling; but this has no relative connexion or analogy with lifting at the leap. On all occasions, the judicious application of the hand or finger, is of the most essential service, and gives the rider a sort of superlative command of the horse which he cannot acquire by other means.

I am an advocate for the double bridle in hunting, and although the animal I rode might be what is called a snaffle bridle horse, and have as delicate a mouth as possible, still I should be inclined to use the double bridle, for the following reasons: the horse more readily answers the hand, and is consequently more manageable; and through heavy and distressing ground, or miry lanes, is much more easily held together. If a horse be suffered to exhaust himself in heavy ground, of course the rider had better return home, unless he have at hand another horse to mount.—It gives me much pleasure to see a sportsman ride boldly; but I like to see him exercise sound judgment also; and unless his courage is accompanied with discretion, it is at best

but a dangerous quality. I would advise every necessary precaution in hunting, as in any other pursuit where the feelings are highly excited; and on this account, I feel no hesitation in recommending the spring stirrup, and the spring bar at the saddle. Some high spirited sportsmen may perhaps despise such precautionary preparations; but that will not alter my opinion. As instruments for common riding, the spring bar and spring stirrup are unexceptionable; while, in case of a fall, I do not think it possible for the horse to drag his rider, since, if the foot, in falling, hangs in the stirrup, the latter must open, if the stirrup leather be not immediately liberated from the saddle altogether by means of the spring bar.

The saddle pommel I would have as low as possible; and the use of the hunting truss and belt are equally advisable.

I have already had occasion repeatedly to advert to the judicious observations of Adams: I will here quote a few lines from him as they cannot be too deeply impressed on the mind of every young sportsman, while their sterling truth will be felt and acknowledged by every veteran: Speaking of the leap, he observes, “I should call it rashness in me, who can sit a horse over any height or distance he can cover, to ride over a rail, bar, or gate, were I not well assured of his steady and safe manner of leaping; and it is equal rashness in a person who has not the knowledge how to sit and support a horse over a leap (be the horse ever so steady and safe a leaper) because the unskilful rider is not only in danger of being thrown, but likewise of balking the horse, making him blunder, pulling him into his leap, and the like.”

*On the Seat when Leaping.*—“The place of the legs (observes Adams) must be perpendicular from the knee; if you place them backward, the action which the body must take, would loosen them and then you have no hold.” Now, I am inclined to think, that the situation of the leg should not be exactly “perpendicular from the knee,” but gently inclining backwards, such a position of the leg enabling the rider to make use of more compressive or adhesive power, and consequently enabling him to sit more closely and more firmly on the saddle; nor have I the least doubt, that, if the reader will take the trouble to try the experiment, he will find I am borne out in such a conclusion. It is true, in a small or ordinary leap, there is no necessity for

any excess of adhesive power, but when a rasper is to be got over, the necessary violence in the action of the horse is so great that the firmest hold with the legs and thighs becomes indispensable; and the position (of the legs) which I have pointed out will be found to be that which is the best calculated to accomplish the object with ease and safety both to the horse and rider.

Young riders can scarcely be induced to lean the body backward enough when the horse has taken his spring, and for this very reason they cannot preserve a motion in consonance or correspondence with that of the horse, and the consequence is, that their seat becomes disordered or disturbed; they are thrown forward and sometimes completely unhorsed. They should lean freely and fearlessly backward; since they may rest assured, it is not possible for them to overshoot the mark or lean too much backward.

Experienced sportsmen, in leaping, frequently elevate the whip hand as the horse is descending, a practise which the professed riding master will by no means tolerate. According to the doctrine of the riding master, the body should be kept square and the whip hand low, as (says he) if the whip hand be raised, the body of the rider must be pulled out of the square, and the balance destroyed. So far it may be said to be all very well; but yet it will scarcely, I think, bear the test of examination. When the horse has taken his spring, and is descending or coming to the ground, the left or bridle hand is necessarily drawn forward; and if, at the same moment, the whip hand be elevated and thrown back, the balance at least of the body is preserved, however it may be drawn out of the square. And here it may be very justly observed, that some horses, when descending, bring their noses lower than others, and these consequently require the accommodation of the bridle hand to a greater extent. In the season of 1824-5, I rode a fine grey mare, that in descending brought her nose very low indeed, and consequently was apt to pull a strange rider out of his seat. Some months before she came into my possession, a gentleman's huntsman (a youth) mounted her for the purpose of following his harriers, but she, in leaping, pulled him over her head; and though this lad attempted to ride her several times, he never completely succeeded in accommodating her peculiar mode of bringing

down her nose. Nevertheless, she was not difficult to ride, and, as a hunter, never perhaps had a superior.

If, however, I feel no disposition to censure the practise of elevating and throwing back the whip hand in the leap, there is another purpose to which I have sometimes seen the same hand applied, in the same operation of the horse, which cannot be too severely censured:—I allude to taking hold of the cantle of the saddle, a method which some few sportsmen adopt either from ignorance, fear, awkwardness, or from some other motive equally reprehensible. To say nothing of the unsightly appearance which such a position presents, the object of the rider is frustrated by the very means which he puts in practise to accomplish it. Taking hold of the cantle of the saddle with the whip hand, renders it impossible for the rider to make use of his bridle hand in a proper manner; consequently he endangers the safety of the horse, and renders his own seat as insecure as possible. A person who adopts this highly injudicious method of riding, is constantly exposed to serious accidents. In the season of 1826-7 Mr. Crosthwaite of Liverpool, thus unfortunately fractured his arm, while hunting with the Liverpool harriers at Ditton.

Riding to Hounds is a business where courage is regarded as an indispensable qualification; but, although I am quite willing to allow to courage whatever may justly be its due; yet it cannot be denied that getting well over a country depends much more upon the judgment; and he that would be a good workman, must unite the two as much as possible, never forgetting, that the former ought to depend on the latter:—"The better part of valour is discretion."

It may be very well observed, that hunting countries vary very much; and therefore the judicious sportsman, or he that would ride well after hounds, must form his judgment and method from the nature and aspect of the country which he has to cross. Leicestershire is uniformly allowed to be the first fox hunting country in the world; and its excellence arises from an union of several fortuitous circumstances:—in the first place, there is a preponderating quantity of grass land; in the next, the inclosures are large; it is but little intersected with rivers; and, lastly, the land, being for the most part stiff clay, it is firm, and consequently well calculated for both hounds and horses.

The fences are, for the most part, quickset hedges, which frequently present high jumps, but which are, nevertheless, in general, better to get over than any other field partitions. The young quickset fences may be said to present rather awkward jumps, as they are protected on each side by rails of a moderate height; but, even these fences have been much improved of late years, since the plan of protecting the young quicksets with a double row of rails merely, without the addition of a ditch, has been adopted. The covers too, which are of the best description, are placed at convenient distances, round which are formed hand-gates; and, indeed, it may be justly remarked, that Leicestershire, naturally well calculated for fox hunting, has received every possible improvement of which it is susceptible from the hand of man. Such is the Leicestershire country with little exception:—Charnwood Forest is perhaps the only material exception, which is hilly, rough, stony and dangerous; forming, however, a good cub hunting country; hunted in the regular season but seldom, and then chiefly for the purpose of rattling out the foxes. The Quorndon hounds, the most numerous pack in England, hunt this country.

At a little distance, on the Rutlandshire side, is situated the splendid fox hunting establishment of the Duke of Rutland. The country hunted by his Grace is not so good as the Quorndon country; and some parts of it are very heavy indeed. On what, for the sake of distinction, I will call the Northamptonshire side (though strictly speaking, the term is not geographically correct) the Earl of Lonsdale's kennels are situated; and his Lordship's country is not equal to the Quorndon. However, these three extensive packs approach Melton Mowbray in different directions; and hence may be perceived the reason why the little town of Melton is regarded as the metropolis of fox hunting.

Northamptonshire, which joins the county of Leicester on the southern side, contains several fox hunting establishments, as, for instance, Lord Fitzwilliam's and the Pychely; but the Northamptonshire country presents a different aspect to Leicestershire, is not so pleasant to ride over, is, in some parts, deep and heavy, particularly in the neighbourhood of the celebrated Field of Naseby. Between Northamptonshire and London the country does not appear so well calculated for fox

hunting; but, from a superficial observation, cannot, I should suppose, be difficult to get over.

Surrey is hilly, in some parts; but there are few awkward fences. The fences in Hampshire are easily got over; but the country is flinty, which renders the riding unpleasant.

If we glance at what may be called the northern side of Leicestershire, we immediately come in contact with Mr. Meynell's fox-hounds. This gentleman's country is situated principally in the southern part of Derbyshire; and is, on the whole, but little inferior to Leicestershire. Lincolnshire is a good scenting country, being for the most part, grass land: it is perhaps the best scenting country in England; but, on the whole, inferior to Leicestershire.

Yorkshire contains more packs of fox-hounds than any other county in England; but this arises, in some degree, from its great extent. Some parts of Yorkshire are well calculated for the sport under consideration; but much of it is difficult both for horses and hounds: the fences are mostly quickset hedges; which, after having attained a certain growth, are cut, and what the farmers, I believe, denominate *plashed*: to speak more intelligibly, the hedge is cut about the middle, leaving the bottom part about four feet high; all the stems or thick wood, however, is cut in a sloping or oblique direction, so that they thus present sharp points upwards, upon which a horse could scarcely fail to be staked should he make the least mistake in jumping them. Such fences are frequently to be met with in the Badsworth country; and also in Lord Harewood's; some parts of the latter I thought very heavy. However, I have enjoyed excellent sport in several places in Yorkshire; some few parts of which I thought equal to Leicestershire.

Lord Darlington's country, part of which is in Yorkshire and part in Durham, I consider an awkward country; and one in which it is difficult to kill foxes.

The variations of countries are indeed very great; and if we look at the north-western side of the kingdom, the aspect is as different as possible from any of those of which I have been speaking. In Lancashire, there are no fox-hounds; in Cheshire, the adjoining county, there are several packs, the principal of which is kept on Delamere Forest (Sir Harry Mainwaring's) which in quality is equal

to any in England; though not so numerous as some other packs.\* Cheshire must be a difficult country for a stranger. The fences (which are of very frequent occurrence) appear no way formidable at a distant view, and their true character is only perceived on a near approach. Generally speaking, they consist of a wide, awkward ditch, the mould from which is formed into a bank, upon the top of which is generally placed a rotten, briary hedge; many of these cannot be taken at a flying leap; and it requires some little practise before a horse and his rider find themselves comfortable in crossing them. Brooks too are not of very unfrequent occurrence; but what has generally surprised me the most in Cheshire is the gate places. The gates, particularly in the immediate vicinity of the farm houses, are very often found wide open; yet, to jump the fence will be sometimes preferable to passing through the gate place! The fact is, the farmers, either from indolence, or some other motive, allow the gate places to become belly deep in wet miry clay, and on this account some of them are absolutely impassable. It is true, I have met with something of this sort in other countries, and even in Leicestershire; but these horrible gate places are of more frequent occurrence in Sir H. Mainwaring's country than in any other which has fallen under my observation. The best part of Sir H. Mainwaring's country, as far as I am able to form an opinion, is that which is situated in the neighbourhood of Nantwich, known by the name of the Wrenbury country.

Sir Thomas Stanley, of Hooton Hall, Cheshire, keeps a pretty pack of fox-hounds; but his country, comprised between the rivers Dee and Mersey, is of small extent; and worse for either horses or hounds than the one which I have just been noticing.

On the Staffordshire side of Cheshire, Mr. Wicksted's hounds frequently appear. This gentleman draws all Sir John Broughton's covers; and his country is composed of part of Staffordshire and part

of Cheshire. It is, like the last, a difficult country for hounds and horses; and where, of course, foxes are difficult to kill.

Without pursuing this subject further, it may easily be imagined that scarcely two countries present exactly the same aspect; and consequently the first object which ought to occupy the attention of the sportsman, as far as relates to riding to hounds, is the nature of the country.

It must also be recollected, that the system of fox hunting has assumed a different character from that which distinguished it a century ago. The heavy slow-hound, the celebrated old English hunter, and the equally celebrated old English sportsman, are no longer known.

The pursuit of the fox was formerly a work of three or four hours; and frequently extended to a much greater length of time. According to the modern system, the business is generally completed in about an hour; and the fox is often killed, but more frequently lost, in half that time. The old English hunter was a large, heavy, powerful horse, whose excellence consisted principally in his leaping or jumping; and, in fact, it may be justly observed, that he was very well calculated for the hounds which he had to follow; but, with modern hounds, he would have been run out of sight in a very few minutes. "*It is the pace which kills,*" an observation common enough in the mouth of a sportsman; one that merits the deepest consideration, and which cannot do otherwise than carry conviction to every reflecting mind. If a horse be pressed, and continued but only for a short time at the top of his rate, he becomes so exhausted that he cannot clear his jumps; and he thus endangers his rider's neck, to say nothing of losing the sport; but, as far as relates to the old English hunter, as the slowness of the pursuit allowed him to go *within himself*, or at his ease, so he was generally able to clear his leaps; and although he might not be able to gallop half as fast as the modern hunter, he might perhaps be as good a fencer, if not better, since even cart horses have been known to clear enormous jumps.

In modern hunting, however, it is indispensable that the horse should possess great speed, if his rider is to enjoy the diversion; and as the business of the chase is so much more rapid than formerly, it requires more judgment in the sportsman in riding to hounds; yet, since no blown horse can be trusted even at a moderate jump, the necessity of keeping the horse's

\* Sir Harry Mainwaring's pack generally consists of something more than sixty couple, and they hunt four times a week. The Duke of Rutland's will number about seventy couple. Lord Darlington keeps about the same number. The Quorndon establishment generally contains nearly one hundred couple, and they used to hunt every day, except Sunday.

wind in him must appear so obvious as to need no further elucidation.

Hitherto I have confined my observations, as far as relates to hounds, to those which are used in the pursuit of the fox; not that I despise harriers: on the contrary, I have frequently enjoyed very pretty sport in harehunting; but as riding to fox-hounds requires so much more nerve and judgment than riding to harriers, so I conclude that he who can ride to the former will experience no difficulty in following the latter. A hare, it is well known, runs in circles; or, in other words, she will rarely go to any great distance from the place where she was found; and on this account, those who are timid, or not fond of hard riding, may partake of the diversion of hare hunting without any great exertion; but this system of diversion is not suited to the taste of a true or keen sportsman; and he that would enjoy the sport even of hare hunting in perfection must ride hard, and should ride well also. If a sportsman ride well up to harriers, he then makes the most of this species of diversion, and assimilates it to the pursuit of the fox as near as the nature of the business will allow; but, inasmuch as harriers uniformly puzzle more than fox-hounds; and as from the very manner of running and turns of the hare, the dogs are frequently coming to trifling checks at least, so, consequently, the sportsman finds little difficulty in keeping well with harriers. On the contrary, the fox, when found, makes away for some certain point; and although he seldom crosses the middle of a field, but skulks along the sides of the hedges, yet his course is comparatively straight; and it requires all the exertions of the hounds, and consequently of the horses, to keep near him. Here too again, the old and the modern system of the chase appear strikingly in opposition to each other. By the former method, the fox was run down; by the latter, the hounds run up to him. The old English fox-hound was slow in the pursuit, but possessed such exquisite sense of smell, that he could follow his game after a considerable time had elapsed:—he might be said in fact, never to be off the scent; and, possessing as he did, invincible perseverance, he ultimately succeeded in his object—he run down or tired out the fox. The modern fox-hound is all dash and spirit; he requires much assistance from the huntsman, on account of the inferiority of his sense of smell: but if he can be kept on the line of the fox, his speed

is so great that the business is generally finished in one fourth of the time which it formerly occupied: *he runs up to his fox.*

Here I must repeat the observation—“*It is the pace that kills.*”—When the fox hound was rendered so fleet, the effect upon the horse was very soon perceived; and welter weights discovered the necessity of having more than one out in the field at the same time; nor indeed is this practice confined to welter weights, since many hard riders, who can afford it, have adopted the same plan. I have been told that the present Earl of Sephton was the first who introduced the system I have just noticed; but of the correctness of this I am by no means certain: on the contrary, I am inclined to think that it was practised in the time of the celebrated Hugo Meynell, Esq. Some years after this gentleman's death, Lord Sephton became master of the Quorndon pack; and, being no feather on horseback, found it very pleasant, no doubt, to have a second (or perhaps a third) horse in reserve. But horses, calculated for his Lordship's weight, were not easily found; and for a horse which was able to carry him fifteen minutes up to the Quorndon hounds, he did not hesitate to give five hundred guineas; for one which could carry him up to them for twenty minutes, eight hundred guineas.

However, I am inclined to think, that one horse ought to be sufficient for one day's diversion; and, generally speaking, such will be found to be the case under ordinary circumstances; but, since the horse is expected to perform his part in a satisfactory manner, it behoves his rider to take care that he is properly treated, by which means his strength, and all his noble and generous qualities, can be used to the utmost advantage, and the horse sustain no injury by long-continued and extraordinary exertion. That the horse is as fond of the chase as the rider is evident, since his eye will be seen to sparkle with pleasure the moment he perceives the preparations for hunting. A horse, on his way to the place of meeting, will frequently manifest the pleasure he feels by a variety of anticks; and when the hounds have been thrown into cover, and are trying for a fox, his impatience for the run is evinced by characteristic indications which are too clear and too expressive to be misunderstood. Nor under any other circumstances will a horse make the same desperate exertions, as in follow-

ing hounds. In the latter end of the season of 1825, I had been hunting for a short time with Sir H. Mainwaring's hounds; and, upon my return home, was mounted upon a mare, which, from having been much overworked, seemed scarcely able to go more than four or five miles an hour. I had something more than twenty miles to ride, and commenced my journey about nine o'clock in the morning. Whitley Gorse, the fixture for that day, for Sir H. Mainwaring's hounds, lay in my road, and as I proceeded, the hounds, with their attendant huntsman and whippers-in, overtook me. The mare perceived the approach of the hounds, before I was aware of the circumstance, and the first signal I received was her lifting up behind so high and so unlooked for, that I was thrown upon her neck. I accompanied the hounds to the cover, which was within a few score yards of the road, and they were no sooner thrown in than my mare manifested a degree of impatience which I had not expected to experience in her jaded state. In a few seconds, a fox was found:—he broke away in gallant style with the hounds at his brush, and my mare testified so strong an inclination to follow, that I indulged her. I was never better carried; and after a brilliant thing of one hour and five minutes, I witnessed the death of the fox. I mention this merely to shew what that generous creature, the horse, will perform under such an excitement as hunting.

Having noticed the impatience which the horse manifests immediately prior to the run, it follows, as a necessary consequence, that, if this impatience be not judiciously restrained and his powers properly used, he must be blown very early in the run. The fact is, the commencement of the run is the most difficult part of the business—it is that which puts the judgment and skill of the rider to the severest test; and the horse should be so managed as to prevent him from exhausting his strength in what may be called the first burst, and yet keeping him well with the hounds. Indeed, it appears to me that the horse goes much more pleasantly to himself as well as to his rider, when he has got what is called second wind; and the same remark is susceptible of a more extensive application. The fox gets second wind, the hounds get second wind, as well as the horse, and the run, which up to this period might be considered as an impetuous dash, becomes

steady, as it were, and every thing proceeds with more regularity. At the commencement of the run, however, young fiery spirits are often as impetuous as their steeds, and, to say nothing of distressing their horses unnecessarily, sometimes mar the sport by riding too forward, or amongst the hounds—perhaps before them. When the hounds have found, they should be suffered to go away with their fox, and get well settled to the scent, without the least interruption—(and yet how often have I witnessed the contrary, in defiance of the entreaties, prayers, and ultimately of the deep curses, of the huntsman).—Nor, indeed, after this period should they be ridden too near or pressed by the sportsman: there should always be a sufficient space between the pack and the sportsmen for the hounds to turn; and indeed, the sportsman may be said to be sufficiently near so long as he can distinctly observe the working of the hounds. As I have already observed, a horse should be restrained at the commencement of the run; but it is the judicious application of this restraint that renders it effective:—horses should not be pulled about as they frequently are by ignorant horsemen, since the remedy then becomes as bad, if not worse, than the disease; and for the proper management of the horse at this juncture, good hands will easily perform what nothing else can properly accomplish: the sympathetic sensibility of the hand may be said to give the rider a complete controul over the powers of his horse, and this excellence can never be more beneficially applied than during the first maddening impetuosity of the run:—and this, particularly, where the animal happens to be high spirited, or of a hot and fiery temperament. Horses of this disposition, like impetuous riders, are anxious to lead; and indeed, it must be admitted that they go more pleasantly when placed in the front rank; and therefore, when such an enviable situation can be obtained, it is advisable to occupy it. Unfortunately this taking the lead often produces injudicious, and indeed injurious, rivalry; inasmuch as sportsmen thus approach too near the hounds, force them beyond the scent perhaps, and create the most vexatious confusion.—It is no wonder that huntsmen are sometimes unable to restrain their temper within due bounds.

I have frequently witnessed instances, where the very free application of the double thong to the shoulders of the of-

fender would have given me the most unqualified pleasure. In the year 1824 (November) I met the Cheshire hounds at Shavington, the seat of Lord Kilmory, and, amongst the assembled sportsmen, one in particular attracted my attention. He had not mounted "*a bit of a pink*," or those other characteristic habiliments which distinguish the fox hunter of the modern school: on the contrary, the very cut and fashion of a vulgar yeoman of the last century—enveloped a dense and weighty mass, not of inert matter, but of as genuine and blunt stupidity, as ever animated the human form. I was anxious to avoid the contact of this semi-barbarian, who seemed to pride himself (as such fellows frequently do) on a degree of impudent activity or forwardness, which was any thing rather than palatable. In defiance of all my precaution, this fellow nearly unhorsed me in passing along a narrow path in the first plantation we entered, and before a fox was found, or a hound had spoke. I consoled myself under the idea that when we went away, I should see no more of Bullstrodonius; but it unfortunately happened that we found a dodging fox: we experienced a variety of trifling checks in consequence, which let him in, and enabled him to ride among the hounds, and exhibit his presumptuous and ignorant arrogance in all possible forms:—how much I wished for Sir Bellingham Graham, or Mr. Osbaldeston!

Every person should, if possible, take his place and keep it; and after the bustle of the first five minutes (supposing the fox goes well away, every thing assumes a degree of regularity, of which before it was not susceptible; and such fellows, for instance, as the one above noticed, are shaken off.

I have already repeatedly observed, that "it is the pace which kills;" and so it certainly is; but this requires a little further elucidation, together with a notice of other circumstances, which demand the serious attention of the sportsman. On coming to a heavy and extensive fallow, it is much more advisable to creep along by the side of the hedge than to cross the field, as the ground is generally more firm near the fence; if the horse can place two of his feet (on one side, of course) upon the little bank or elevation, which remains untouched by the plough, it will be much less fatiguing to the horse than if he sunk considerably with all fours at every stroke. If, however, it

becomes indispensably necessary to cross a heavy fallow, the horse should be held well together, or if he even trots over, so much the better: a horse is naturally inclined to labour hard through very heavy or miry ground, and if left to himself would be completely blown and exhausted in a few minutes. Hence, if a horse be suffered to rip and tear over a heavy fallow, he will run into the next leap, or perhaps be so exhausted as to come to a stand; whereas, if the animal had been held well together, and have thus been compelled to occupy a few more seconds in the operation, he would come to the end within himself, and consequently in a state to proceed. Under the circumstance of a heavy fallow or any similar occurrence, if a horse loses a little ground in going slowly over it, he is better enabled to make play where the ground will admit of his so doing without unnecessary distress.

As a general rule, it may be observed that the horse should be allowed a little respiration on every possible occasion; that is, he should be suffered to remain stationary whenever opportunities occur; even if it be but for a few seconds, the horse will derive great benefit from it; and a run seldom takes place, where such opportunities do not present themselves. Further, when a horse is in any degree exhausted, he should either be turned round at his jumps (unless indeed they are very small) or be reined in for a few seconds, by which means he will be more likely to clear them.

Hence the sterling truth of that axiom, which I have already noticed, namely, that "it is the pace which kills," may be clearly perceived in more bearings than one. Generally speaking, for instance, to keep a horse at great speed not only soon exhausts him for the present, but its frequent repetition destroys him entirely:—a striking exemplification of which may be seen in the horses which run in the very fast coaches, to say nothing of hunters. So also, in going over heavy ground, if a horse be suffered to extend himself, the pace must kill him. At the same time, it may be justly observed, that the frequent occurrence of jumps is very distressing to a hunter; and hence Cheshire, Lancashire, and indeed all this part of England may be regarded as a very distressing country. The act of leaping or jumping requires more than ordinary exertion in the horse; and, of course, the extra exertion will be regulated

by the nature or extent, or both, of the jump.

Generally speaking, I would advise sportsmen to avoid, as much as possible, all jumps with stiff or unbending tops, since, however perfect a horse may be, mistakes, or *misfootings* may occur; and as an elastic or weak fence will give way to the weight of a horse, so I consider it preferable to a gate, style, rail, or wall. It is true, there are (particularly Irish horses) many horses very clever at jumping timber and walls; yet, for the reasons already stated, I should prefer the elastic fence, and only put the horse's abilities to the test in regard to the former, where it appeared absolutely necessary.

Walls, unless they are low, I cannot help considering as awkward jumps, though I am very well aware they are nothing thought of in the sister kingdom; the fact is, they are common occurrences: as walls constitute the principal part of the fences of Ireland, the horses are familiarized to them from the earliest periods of their existence, and hence become the best wall jumpers in the world:—a horse indeed is sure to excel in that species of leaping to which he has been the most accustomed. Brooks, when the banks are sound, are no serious obstacles, unless wider than the horse can cover; but the worst of brook jumping is, the banks are seldom to be depended on, and hence serious accidents sometimes result—to the horse at least, if not to the rider. If the bank happens to give way, on the side from which the horse is taking his spring, he is very liable to break his back or receive some serious or incurable injury. Sir Harry Goodricke (if my information be correct) thus lost one of the best hunters that was ever seen at Melton. He had been offered seven hundred guineas for him, and the horse, some little time afterwards, broke his back owing to the bank of a brook giving way, over which he was about to jump. If in crossing a brook, the sportsman can contrive to put his horse at it where the banks slope towards the water, he is more likely to get safe over, as, in such places, the banks are seldom undermined by the action of the water—the hollow banks are, of course, the most to be dreaded. In going at a brook, it is the most advisable to put the horse very smartly and vigorously at it; the same remark is equally applicable to a gate; and indeed any large and rasping leap.—In regard to gates, I honestly confess I am seldom disposed to jump one,

where I can conveniently open it; and there are few horses that will not, with a little practise, become very handy at opening gates.

In crossing a country, the sportsman should keep a look out forward: as soon as he is over one fence, he should cast his eye to the next, and direct his horse to the most convenient spot to get over, consistently with keeping his place.

As to the best mode of teaching a horse to leap, which is intended for hunting, I have little hesitation in asserting that the bar is of very little service. In the first instance, I should feel no objection to put a young horse over the bar, to teach him to bend his knees; but, it is in the fields where he must acquire a knowledge of his business; and on this account he should receive his instruction in the fields. His lessons, however, should never be unreasonably extended, or he will become disgusted; a horse seldom jumps willingly unless after hounds. When a young horse takes his exercise, he may be put over a few fences, and this perhaps is the best way of imparting the necessary instruction.

The ornamental airs of the manege have no connexion with the operations of hunting; on the contrary, they force the horse into unnatural positions, and must very much strain the sinews or tendons. A high drest horse cannot be fleet, nor indeed scarcely useful. This method of riding is considered as highly ornamental, and that is all that can be said of it.

As the opinions of experience are always valuable, particularly when they emanate from a sound understanding, and a well cultivated mind, so in the present instance, I will quote the observations of Mr. John Lockley, a veteran sportsman, the friend and companion of the justly celebrated Hugo Meynell, a man who had the most extensive and the best opportunities of forming a judgment upon the best method of riding to hounds:—the observations in question were put together at the earnest solicitation of a numerous circle of friends, of the first respectability, amongst whom they were circulated, but were not originally intended for general publication:—

*“Anticipating a check, and making a judicious cast (when casting is necessary) is the most useful knowledge in hunting.”*

“At a time when all the world run mad about fox hunting, I am surprised so few gentlemen have learned to enjoy it rationally: the fashion of the present day is

*hard riding* ; and, at night, when over the convivial board, their only pleasure seems to be in relating the exploits or disasters of their own or their friends' horses ; not a word about the best or the worst hound in the pack : or any idea ever started to ascertain whether, by *system*, or by *accident*, they had continued to carry a scent twenty miles over a country, to kill a fox ; and how so great an event has been achieved, few modern sportsmen can, with any degree of accuracy, relate.

“Many years ago I recollect a gentleman who kept ten horses in Leicestershire, and who had been riding near me often in a very fine run, in which two of the most beautiful and interesting things happened I ever remember to have seen, and to whom I remarked them when the run was over :—‘Good God, Sir, (said he) I saw nothing of it!’ This was a hard rider, who, from his own account, saw *nothing* while riding his horse as hard as he could go, and as near the tail of the hounds as he could possibly get ; and how should he ? for a man behind the hounds cannot be a judge of what is going on in front, and is the first person (by pressing upon them) to bring them to a check.

“A good sportsman will, as often as possible, ride parallel with the pack, not after them, unless, by short turns, he is obliged to do otherwise ; by which means he can see every thing that is going on, and anticipate the probable cause of hounds coming to a fault : and I believe a good huntsman, and a minute observer, will, twice out of three times, discover the object in the line of the hounds that caused it, and, as soon as he suspects it, pull up his horse :—for instance, a church, a village, a farm house, a team at plough, men at work, sheep, and, above all, cattle, are the things most likely to impede the scent : (be it remembered, that the breath of one cow will distract hounds more than a hundred sheep :) when any of these objects present themselves in the face of the hounds, you may then anticipate a stop ; and by pulling up your horse, and observing which way the pack inclined before the check, you will be able (without casting) to hold them to the right or left accordingly.

“If casting is necessary, you should be directed by the pace, or degree of scent which you brought to the spot where the hounds threw it up ; if you come quick, and your hounds are not blown (be sure to attend to that ;) you may make a quick cast in the direction which the hounds were inclining, by forming a small circle

first, and a larger circle afterwards, if you are not successful ; but if the hounds are blown, you should invariably cast them very quietly and hold them back ; for when hounds have run a long way hard, they lose their noses for want of wind, and run beyond the scent, especially if there is water in their view.

“In a fair country, and hounds in condition, it is my opinion, that if the above observations could be carried into effect, few foxes would escape. Patience is the best performer in the chase ! All hounds in these times are well enough bred, and all hounds have power enough (if judiciously directed) to kill their fox.”

When the founder of the Quorndon establishment, the celebrated Hugo Meynell, Esq. had become grey in the service of fox hunting, he was in the habit of addressing mild expostulation to the fiery sparks who attended his hounds, and frequently remarked that he wished there had been no such word as *forward* in the English language, which sufficiently shews the coincidence of opinion on the subject of fox hunting between him and Mr. Lockley.

If we consider the preceding remarks as applicable to fox-hounds particularly, it will be necessary here to observe, that in riding to harriers still more caution is indispensably requisite, or the sport is utterly ruined. When a fox is the object of pursuit, the lane riders (and some of these generally attend the meetings of fox-hounds) when once *renard* has fairly gone away, have no opportunity of doing mischief, as the fox seldom returns or accommodates their mode of riding ; but the case is different with harriers : hares seldom run far from home—they will frequently run along the lanes for a considerable distance, and thus afford the lane riders an opportunity (which they seldom fail to embrace) of not only riding too close to the hounds, but even into the middle of the pack, laming some of the dogs perhaps, and causing the greatest confusion. In the pursuit of the hare, checks should be constantly expected, and are indeed of never-failing occurrence ; and, as in these cases she is generally behind the hounds, so a space sufficiently large for the hounds to cast themselves back, should always be left between the sportsmen and the dogs.

**HORSE-SHOE** is a plate of iron for the preservation of the foot. See **SHOEING**.

**HORSE-RACING**. See **TURF**, the.

**HOUND A STAG.** To hound a stag is to cast the dogs at him.

**HOUNDS.** These animals are objects of more than ordinary interest to the sportsman; and though there are at present hounds of all sizes, all forms, and all colours, little doubt can be entertained that these varieties have sprung from one original stock, namely, the talbot, or old English blood hound.

As far as an opinion can be formed on the subject, there is reason to believe, that the talbot was originally introduced into this country by the Normans; and perhaps it would be difficult, if not impossible,

to meet with a single specimen of the pure and uncontaminated stock from one end of the kingdom to the other. From what has been written on the subject, it would appear, that the dog in question was about seven or eight-and-twenty inches high, and of a very strong and muscular form: the face very wide across the forehead, nostrils large and expansive, with large, soft, flexible lips, large and long ears, and the head altogether of more than the ordinary size; with a voice awfully loud, deep, and sonorous.

The following is Somerville's description of this highly interesting animal:—

“—If the harmonious thunder of the field  
Delight thy ravish'd ear, the deep-flewed hound  
Breed up with care, strong, heavy, slow, but sure;  
Whose ears down hanging from his thick round head  
Shall sweep the morning dew, whose clanging voice  
Awake the mountain echo in her cell,  
And shake the forests: the bold Talbot kind,  
Of these the prime as white as Alpine snows,  
And great their use of old.”

Hence it will be seen that Somerville seems to think the pure talbot was “white as Alpine snows:” while others assert, that “one distinguishing trait of the purity of the breed is said to have consisted in the colour, which was uniformly and almost invariably a reddish tan, gradually darkening to the upper part, with a mixture of black upon the back becoming some shades lighter in reaching the lower parts and extremities.” Pennant, in his delineation of quadrupeds, mentions them as having a black spot over each eye. But all these opinions in regard to the colour of the talbot exhibit much more of fancy than philosophy; though, from very considerable observation and much inquiry, on the subject, we are inclined to believe, that though the talbot might vary in colour, yet the darker shades would be found most prevalent. We feel persuaded that the talbot in general was dark coloured, with red or tan spots over his

eyes, something similar to what may be seen in many of the deep-flewed southern hounds:—in fact, the southern hound would appear a smaller kind of talbot; and hence, for the purpose of forming an opinion, the reader cannot be referred to a better object of comparison. The singularly commanding appearance, and attracting aspect of this dog, when seriously surveyed, seems to convey a consciousness of his own superiority; the uncommonly intelligent eye, the massive and capacious nose, large and pendulous ears, his strength of form, and his deep loud voice, produce, very impressively, the idea of a superior animal.

Our immortal Shakespeare notices these dogs; and when it is considered that he was, at an early period of his life, a professed deer-stealer, it is highly probable he might have had many opportunities of observing hounds of the talbot kind, or something very similar: he says—

“My hounds are bred out of the Spartan kind,  
So flewed, so sanded; and their heads are hung  
With ears that sweep away the morning dew;  
Crook-knee'd and dew-lapped, like Thessalian bulls.”

At all events, the great and distinguishing peculiarity of the talbot was his extraordinary olfactory organs, or powers of smell, by which he was enabled to carry on any scent to which he was trained with almost infallible certainty. It will easily

be perceived how this surprising faculty was derived, by referring to the article **FOX HUNTING**, where, in an extract from Johnson's *Shooter's Companion*, the matter is explained

It has been remarked by a writer, that

on the divisional borders of England and Scotland, while those countries were waging war against each other, the principle of morality was, in a great degree, extinct, and private robberies were sanctioned as mere military excursions. What in war the leader seized by force of arms, his vassal stole under the covert of the night, and drove his prize in darkness far within his own district, or secured it in fastnesses from whence there was little or no chance of extrication. In instances of this kind the hound under description was of the utmost utility, in tracing either the thief or the articles which had been stolen. And while the then barbarous, inveterate, and unrelenting clans of the north, under petty chiefs, were perpetually engaged in civil broils, the vanquished, who fled from the sanguinary conflict, were often hunted from cave to cave by a dog of this description, and slaughtered in cold blood. In addition to this, it is mentioned by Bewick, in his work upon quadrupeds, that, at the period alluded to, there existed a law in Scotland, by which it was enacted, that whosoever obstructed a dog of this description in pursuit either of stolen goods, or the offender, would be deemed an accessory to the theft.

We are told that those dogs designed for one particular pursuit, and used merely as blood-hounds, were never brought into the chase with any pack for the promotion of sport with any species of game; but were preserved and supported (as a constable or bow-street officer of the pre-

sent day) for the purposes of pursuit and detection. But this is mere conjecture, as very little doubt can be entertained that they were used by the Normans, (with whom they were great favourites) in the sports of the field, and in the sports of the field alone. It is true, from their extraordinary powers of smell, they were afterwards employed for other purposes. The border marauders, just before mentioned, were unquestionably pursued by these dogs; and no doubt can be entertained that it was from observing the animal's surprising capacity for carrying on any particular scent that originated the idea of employing them for that purpose. In this species of employment, they had frequently to pursue their object through morasses and boggy grounds (of which those will have a good idea who have visited the moors) and thence acquired the appellation of *sleugh* (slough) hound, sometimes written *sluth* hound.

They were, a century or two ago, used in England for the purpose of pursuing deer-stealers; and an offender was regarded as certain to be taken the moment a blood-hound could be laid upon the scent.

There was a law in Scotland that whoever denied entrance to one of these dogs in pursuit of stolen goods should be deemed an accessory. This property of discovering the nightly prowler by the unerring accuracy of its scent is thus beautifully noticed by the poet of the chase:—

— Soon as the morn  
Reveals his wrongs, with ghastly visage wan,  
The plundered owner stands, and from his lips  
A thousand thronging curses burst their way:  
He calls his stout allies, and in a line  
His faithful hounds he leads, then with a voice  
That utters loud his rage, attentive cheers:  
Soon the sagacious brute, his curling tail  
Flourish'd in air, low bending, plies around  
His busy nose, the streaming vapour snuffs  
Inquisitive, nor leaves one turf untry'd,  
Till, conscious of the recent stains, his heart  
Beats quick; his snuffing nose, his active tail,  
Attest his joy: then with deep op'ning mouth  
That makes the welkin tremble, he proclaims  
Th' audacious felon; foot by foot he marks  
His winding way, while all the list'ning crowd  
Applaud his reas'nings. O'er the watery ford,  
Dry sandy heaths, and stony barren hills,  
O'er beaten paths, with men and beasts distained,  
Unerring he pursues, till at the cot  
Arrived, and seizing by his guilty throat  
The caitiff vile, redeems the captive prey:  
So exquisitely delicate his sense!

In speaking of the pursuit of Robert Bruce by Edward I. an old manuscript says,

The king Edward with horn and *hounds* him sought,  
With men on foot, thro' marshes, moss, and mire,  
Thro' woods also and mountains where they fought.

To try the merit of a young blood-hound, a nobleman (says Mr. Boyle) caused one of his servants to walk to a town four miles off, and then to a market town three miles from thence. The dog, without seeing the man he was to pursue, followed him by the scent to the above mentioned places, notwithstanding the multitude of people going the same road, and of travellers that had occasion to cross it. When the hound came to the market town, he passed through the streets without noticing any of the people there, till he got to the house where the man he sought was, and there found him in an upper room.

The author of the Sportsman's Cabinet has fallen into a most egregious error in speaking of the blood-hound:—he says, "Having gone through every thing appertaining to this description of dogs in Britain, we naturally refer to the use made of them in other countries, *where the breed is still preserved*, and held in the highest estimation, more particularly at and near the Havannah, in the island of Cuba, from whence they were procured for the prosecution of the late Maroon war, which took place some years since in the island of Jamaica." Hence from this account it would appear, that the talbot or old English blood-hound, and the blood-hound of the West Indies, were the same breed of dogs precisely; whereas they differ from each other as much, or nearly so, as any two ramifications of the dog. The old English blood-hound we have already described; and it therefore only remains to observe, that the blood-hound of the West Indies is merely a very large and a very ferocious dog, with small ears, and altogether more like an enormous lurcher than any thing of the hound tribe. Dallas, in his account of the Maroon war, expressly states that these dogs were generally accompanied by smaller ones for the purpose of carrying on the scent, or following the foot of the negro, as the larger ones were frequently incapable of tracing the path of the object themselves. Besides, the very circumstance of the small ears of the West India dog shews at once the immeasurable distance to which he is removed from the talbot; and it is

also an incontestible indication of his very inferior organs of smell.

The author of the Rural Sports (Mr. Daniel) when speaking upon the subject, falls into a similar error; and indeed this as well as many other parts of the works of both these gentlemen, manifest the very superficial knowledge (and not unfrequently gross ignorance) which they possessed of those subjects upon which they have both professed to write.

We have remarked in the early part of this article, that a pure talbot is hardly to be met with: hounds, however, nearly approaching the talbot may be sometimes observed at the establishments of those who keep deer, which are retained, it seems, principally for the purpose of recovering a stag which happens to leap the park wall, or indeed for driving in the outlying deer. The Earl of Derby's first gamekeeper, shewed the writer two of these dogs in the summer of 1824. Lord Anson has also several, if our information be correct, as well as Lord Howe at Gopsall; and others are no doubt to be met with.

It must not however be supposed, because these dogs were principally employed in following the footsteps of man, that they possessed any pre-disposition for this peculiar pursuit; on the contrary, they would equally follow the scent of fox, deer, or any other animal, or indeed any particular scent to which they were trained; and the reason no doubt why they were selected for the purpose just mentioned was owing to their superior nose, which enabled them to trace the original scent upon which they were laid, through every possible winding and intricacy.

*The stag-hound* may be regarded as the first remove from the blood-hound—we mean the stag-hound of ancient days; for in some of the stag hunting establishments of the present day, what might be justly regarded as fox-hounds are employed instead of the old fashioned and heavier stag-hound; as a case in point, we may instance those of the Earl of Derby.

Stag-hounds are rarely kept, and the sport but little known in many parts of the kingdom: those of the most celebrity are the royal establishment upon Ascot

Heath, in Windsor Forest, and the Earl of Derby's, at the Oaks in Surrey. There are stag-hounds kept in other parts of the kingdom, but they are of minor importance.

Beckford, whose admirable Letters on Hunting, have rendered his memory immortal, seems not to have possessed a clear idea of the nature of hounds; as he remarks, that, could the fox-hound distinguish the hunted fox as the stag-hound does the blown deer, it would then be perfect. Now, the reason why the stag-hound could discover the blown deer from the herd was owing to the superiority of his olfactory organs. He was the first remove from the talbot; while the fox-hound was the fifth or sixth; and, in the latter, speed has been gained at the expense of nose; or, at least in acquiring that speed for which the fox-hound is distinguished, the preservation of acute olfactory organs has not been sufficiently attended to—in fact, it has not hitherto been sufficiently understood. It is necessary to observe, that Beckford's remarks upon the subject under consideration, or at least his comparative observations, were made on the stag-hounds used formerly, with fox-hounds of his own times; for, as it has been already observed, the Earl of Derby pursues the stag with hounds very similar to fox-hounds, dogs, which, we hesitate not to state, from personal observation, could no more distinguish the blown deer from the herd than fox-hounds could the hunted fox. This object, to be attained, in either stag or fox hounds, must arise from the superiority or acuteness of the powers of smell; as it is not derived from the difference of the object of pursuit; and we are inclined to believe, that the stag-hounds which possessed the faculty of distinguishing the blown deer, would have distinguished the hunted fox (had they been trained to fox hunting) with as much ease at least, if not more.

The stag-hounds used by his late majesty George III. were large powerful hounds, larger than those used at present by the Earl of Derby; and a year or two back, there were stag-hounds in Devonshire which resembled those used for the purpose in ages past away; but probably by the time these observations meet the eye of the public, stag-hunting in Devonshire will have ceased altogether.

*The fox-hound* comes the next under consideration, not on account of his close alliance in blood to the stag-hound or tal-

bot, but from his size, as well as from the nature of the chase for which he is appropriated.

The modern fox-hounds are, for the most part, tall, bony, fleet dogs; as the attention of breeders has been directed to power, speed, and perseverance, the olfactory organs have been neglected; and hence in many of the fox hunting establishments of the present day, the hounds are not able to hunt unless under the most favourable circumstances; and even then, it will frequently be found, that the success of the chase depends upon two or three hounds (perhaps only one) whose heads happen to be larger than the rest; and whose powers of smell, in consequence, are much superior.

The writer recollects a hound in the pack of Mr. Hay, in the year 1824, when that gentleman hunted in Shropshire, named Gaoler, with a remarkably large head, and on that account he was deemed unhandsome; but this dog uniformly displayed his superior nose on all occasions whenever acuteness of smell was rendered necessary, and that too in the most striking manner.

We are perfectly aware that a heavy, slow hound is not well calculated for the pursuit of the fox, however exquisite his nose may be; since, if hounds have not sufficient speed to press their fox—if they cannot run well up to him—if, in fact, the fox be suffered to listen at his leisure to his pursuers, and regulate his pace accordingly, he will keep them going all day. Very few foxes would be killed by heavy slow hounds; and even foxes which happened to be run into by such dogs would be merely tired out, and not killed with that impassioned spirit, and in that style, which renders the fox chase so superior to all other sports of the field.

Hence it will easily be perceived, that the great desideratum would be to unite strength and persevering speed with exquisite olfactory organs; the chase of the fox would then be complete according to Beckford's notion, and a similar opinion, we think, must be entertained by every one who duly considers the subject. The assistance of the huntsman would be thus rendered much less necessary, the chase would become a more regular continuity, as it were, and a more uniform certainty would attend it. If, by an improvement in the powers of smell, the hound were rendered a shade slower, the chase would become more certain, and would, in all probability, be brought to a close equally

as soon, in general, if not sooner, by such hounds being much less liable to check.

But the question is, whether exquisite olfactory organs might not be grafted upon the present speed of the fox-hound: we are of opinion that they might, by proper attention; and the case of the hound Glider, mentioned under the article *FOX HUNTING*, p. 315, forms a sort of presumptive proof that such a desirable object is susceptible of accomplishment.

The tone of the voice or cry of the hound, is another object of consideration. Nothing is more pleasing than the music of the pack; but to regulate the cry so as to produce that unison of sound—that complete harmony which we sometimes hear mentioned, that, in all probability, must be left for the hare hunter to accomplish; and it would appear that an excess of music was by no means consistent with uncommon speed, or at least with that degree of speed so essential in the pursuit of the fox. Even harriers, and those too tolerably deep-flewed, will occasionally run nearly mute. Instances of this sort have repeatedly fell under the observation of the writer, when the atmosphere has been very propitious, and the ground remarkably good for retaining the scent. The reason is clear—when dogs run at their utmost speed, they are not able to open loudly.

Of the persevering spirit of the fox-hound, the following are remarkable instances:—

Many years since a stag was hunted from Whinfield Park, in the county of Westmoreland, until by fatigue or accident the whole pack was thrown out, except two fox-hounds, bred by Lord Thanet, who continued the chase during the greatest part of the day. The stag returned to the park from whence he had been driven; and, as his last effort, leapt the wall, and died as soon as he had accomplished it. One of the hounds ran to the wall; but being unable to get over it, fell down and almost immediately expired: the other hound was found dead about half a mile from the park. The length of the chase is uncertain; but as they were seen at Redkirks, near Annan, in Scotland, distant by the post road about forty-six miles, it is conjectured that the circuitous course they took, could not make the distance ran less than *one hundred and twenty miles!*

A couple and a half of young fox-hounds having followed Colonel Pearson, who was on horseback, strayed into a

large cover by the road side, and presently found something which they very eagerly hunted. After trying for a long time to call them off, Colonel Pearson proceeded to Colchester, where business detained him some hours. Upon his return he still heard them in the cover, and found by some people at work by the side of it, that the dogs had continued hunting during his absence, and had driven a fox over the field in which the workmen were, backward and forward, several times. Colonel Pearson then encouraged them; and after hunting the fox a long time in the cover, he at last broke, and was killed after a run of some miles. The time that these three hounds were running was at least *seven hours*, and by far the greatest part of it they had no person to encourage them to persist.

Mr. George Baker's Romulus broke away singly with a fox, and killed him after a chase of *eighteen miles*.

Upon the 19th of February, 1783, a fox was unkennelled near Boroughbridge, in Yorkshire, at twenty-seven minutes past nine, and except half an hour taken up in bolting him from a rabbit burrow, the hounds had a continued run until fourteen minutes past five, when they killed. During the space of nearly eight hours' hard running, several horses died in the field, and many others were so hurt as never to be perfectly recovered.

It might be supposed from the extraordinary length of some of these runs, that the hounds had changed their fox; and we have already stated that the fox-hound does not possess sufficient acuteness in the powers of smell to discover the hunted fox from another—this must be left to the huntsmen.

The sagacity of a fox-hound, when Mr. Taylor and Mr. Smith had their hounds at Whinnick, in Northamptonshire, and used sometimes to go to Lutterworth, in Leicestershire, for a fortnight's hunting, would appear an exercise of a reasoning faculty beyond the power of mere instinct. A favourite hound was left in Northamptonshire, on account of not being quite sound. The first day's hunting from Lutterworth produced an extraordinary chase, in which the hounds and horses became so fatigued that it was deemed necessary to stop that night at Leicester. Upon their arrival the next day at Lutterworth, they were told that a hound (which answered the description of that left in Northamptonshire) came there soon after their going out the preceding

morning, and waited quietly till towards the evening, when he manifested symptoms of uneasiness, and in the morning had disappeared. It was concluded that, disappointed of finding his companions where he expected, the hound, whose name was Dancer, had returned to Whinnick; but, to the surprise and concern of his masters, upon their returning home, they were informed, that the hound had come back from Leicestershire, staid one day at the kennel, and then left it. Every possible enquiry was made, and at length it was discovered that Dancer, upon not finding the pack at Lutterworth or Whinnick, had proceeded into Warwickshire, to a Mr. Newsome's, where the hounds had been for a week some months before.

The speed of the fox-hound was clearly ascertained by the celebrated contest between the late Mr. Meynell, who so many years conducted the Quorndon establishment, and the late Mr. Barry, who had the direction of the Cheshire fox-hounds, the kennel of which was situated on the borders of Delamere Forest, in the county just mentioned.

A match was made for five hundred guineas for a race between Mr. Barry's Bluecap (four years old), and Wanton (three years old), against Mr. Meynell's Richmond, and a favourite bitch. After the match was made, the celebrated Will Crane was applied to, to train the hounds of Mr. Barry, and he objected to dogs that had been entered some seasons, and wished for young hounds, which would with more certainty be taught to run a drag; however, the hounds were sent to Rivenhall, in Essex, and as Crane suggested, at the first trials to induce them to run the drag, they took no notice; at length, by dragging a fox along the ground and then crossing the hounds upon the scent, and taking care to let them kill him, they became more handy to a drag, and had their exercise regularly three times a week upon Tiptree Heath; the ground chosen was turf, and the distance over which the drag was taken was from eight to ten miles. The training commenced the first of August, and continued until the 28th of September (the thirtieth the match was ran): their food was oatmeal and milk and sheep's trotters. Upon the 30th of September the drag was drawn (on account of running up the wind which happened to be brisk) from the Rubbing-house at Newmarket town end to the Rubbing-house at the starting post of the Beacon

Course; when the four hounds were laid on the scent. Mr. Barry's Bluecap came in first; Wanton (very close to Bluecap) second. Mr. Meynell's Richmond was beaten by upwards of one hundred yards, and the bitch never run in at all. The ground was crossed in a few seconds more than eight minutes. Three score horses started with the hounds. Cooper, Mr. Barry's huntsman, was the first up, but the mare that carried him was rode quite blind. There were only twelve horses up out of sixty; and Will Crane, who was mounted upon a king's plate horse, called *Rib*, was in the twelfth. The odds before running were seven to four in favour of Mr. Meynell, whose hounds, it was said, were fed during the time of training entirely with legs of mutton.

The late Colonel Thornton, so celebrated in the sporting world, produced unquestionably the finest and the fleetest fox-hounds of his time. Merkin, a bitch belonging to the Colonel, challenged to run any hound of her year five miles over Newmarket, giving 220 yards for 10,000 guineas. Merkin had run a trial of four miles, which distance she performed in seven minutes and half a second. The bitch was sold in 1795 for four hogsheads of claret, and the seller to have two couple of her whelps.

Madcap (belonging to the same person) at two years old challenged all England for five hundred guineas. Lounger, brother to Madcap, did the same at four years old. The challenge was accepted, and a bet made for two hundred guineas to run Mr. Meynell's Pillager. The parties were allowed by Colonel Thornton to start any other hound of Mr. Meynell's, and Lounger was to beat both; but, upon Lounger's being seen at Tattersall's by many of the first sportsmen, his bone and form were found to be so capital, that it was thought proper to pay forfeit, which was done, by presenting Colonel Thornton with a pair of gold couples.

Lounger was afterwards sent as a present to the late Duke of Northumberland, as a stallion hound. It is said his Grace's keenness after the sport exceeded that of most other fox hunters that ever lived. In one instance, after a very severe chase, he ordered the fox's head to be *devilled*, and ate a great part of it.

The merits of the Duke of Grafton's celebrated fox-hound Trouncer has been versified by Bloomfield:—

Poor faithful *Trouncer*! thou canst lead no more;  
 All thy fatigues and all thy triumphs o'er!  
 Triumphs of worth, whose long excelling fame  
 Was still to follow true the hunted game;  
 Beneath enormous oaks, Britannia's boast,  
 In thick impenetrable covers lost:—  
 When the warm pack in fault'ring silence stood  
 Thine was the note that roused the list'ning wood;  
 Rekindled every joy with tenfold force,  
 Through all the mazes of the tainted course.  
 Still foremost thou the dashing stream to cross,  
 And tempt along the animated horse;  
 Foremost o'er fen or level mead to pass,  
 And sweep the show'ring dew-drops from the grass;  
 Then, bright emerging from the mist below,  
 To climb the woodland hill's exulting brow.  
 Pride of thy race! with worth far less than thine,  
 Full many human leaders daily shine!  
 Each sportsman heard the tidings with a sigh,  
 When Death's cold touch had stopt his tuneful cry;  
 And though high deeds, and fair exalted praise,  
 In memory liv'd and flow'd in rustic lays,  
 Short was the strain of monumental woe—  
 "Foxes, rejoice! here \* buried lies your foe."

In a prefatory Essay which some time ago appeared to an edition of Somervile's *Chase*, we find the following remarks:—"The heightened expence of every article has much reduced the number of packs of fox-hounds, most of those now kept being supported by subscription, and the subscribers, being chiefly composed of young men of rank, too mercurial to remain in any one place, who are one day in St. James's and the next morning by the side of a fox cover an hundred miles distant; and who are led there by the certainty of meeting a number of their companions, not so much in the hazard of the day, as for the *hazard of the night*; who understand very little of what constitutes the beauties of the chase, and are perfectly indifferent, if they only go fast enough, whether a red-herring or a fox be the object of pursuit. Mr. Meynell once endeavoured to stop a young man by telling him "he was a mile before the hounds."—"Am I?" said the gentleman, "I really did not *know it*. Pray, Sir, can you give me the smallest idea where they

are?" This accident might very easily happen, since the above mentioned personages assemble only at the side of a cover, at twelve o'clock at noon, for a burst of fifteen minutes, to try a few light weights and full blood horses. Fox-hunting has now become a match of time, and the *race* might as well be run without hounds as with them.

He continues—With the former style of fox-hunting, the *old English Hunter*, which, taken for all in all, was unquestionably the best native horse of the country, is now no more to be seen; for in the whirl of a modern sportsman's brain, he is scarcely fit for a currie.

Whether the new school of fox hunting be preferable, the writer pretends not to determine; but, speaking as a poet, if not as a sportsman, he asserts, the varieties of the chase are all gone by. How could any writer, as a fox hunter, describe that day break he never sees? How could any man, yawning in bed at eleven at noon, give us the following:—

"Hail! gentle dawn! mild blushing goddess, hail!  
 Rejoiced I see thy purple mantle spread  
 O'er half the skies. Gems pave thy radiant way,  
 And orient pearls from every shrub depend."

In the opinion of the *old school* of fox hunters, the chase has certainly now become a system of slow coursing; for, having lost the cry of the hounds, without

\* Inscribed on a stone in Euston Park wall.

having acquired the velocity of the greyhound, no compensation has been derived for all the grander beauties of fox hunting, and which was a species of chase peculiar to England alone. It is singular that while the greyhound has been improved in beauty, speed, and strength; while the art of shooting flying has been nearly brought to a certainty, the advances in hunting have been entirely retrograde; for while the animal, whose characteristics should be a good nose and good bottom, has been so increased in speed as nearly to run by view, and instead of that cry, which is to make the welkin ring, his velocity obliges him to run mute; while at the same time the race horse supplies the place of the old English hunter, and from this circumstance the price of a horse, capable of carrying weight to keep up with these speedy hounds, is advanced from forty guineas to three hundred—may it not fairly be asked, whether all these costly changes are any improvements in the system? or, have we not, by these innovations, forgotten what hunting is? If killing foxes be any proof, the owner of the celebrated horse Matchem, who rode *twenty stone*, and that he might not be left in the back ground, his huntsman weighed *eighteen*, and the whipper-in *sixteen* stone: this hunting trio were certainly not *three feathers*, and they rode through as difficult a country as any in England, which was near Newcastle upon Tyne; yet, notwithstanding all these seeming drawbacks, few packs of hounds kill more foxes, although the foxes of that day ran as stout and as fleet as those of the present, and the country was more wooded; but had the present high blooded horses been then thought as essential to hunting as they are now, where in all Europe could have been found the man who could so easily have supplied himself with them as the owner of Matchem? In his time, a hunter was one thing and a racer another. In our days they are one and the same; and the qualification for our hunters' stakes consists in walking a race horse in his sheets into the same field where hounds are, and, in the phrase of the turf, letting him look at them, and from which he really becomes as much of a hunter as the man who rides him."

There is no modern sportsman, however, who will not easily perceive that the foregoing is a very jaundiced and illiberal view of the matter. Beyond all question, fox hunting has been improved perhaps beyond any other field sport; though with

respect to the hound, we are not prepared to deny, that in some cases, mere speed has been allowed to supersede all other considerations. It is some time since the above ill-natured remarks were put together; and what the author asserts in respect to the number of fox hunting establishments is completely at variance with the present period, as there never was a time, when England contained so many as at present, and many of them on a very extensive scale.—the Quorndon foxhounds (when Mr. Osbaldeston had the management) hunted every day in the week, the greater part of the season, Sundays only excepted.

Of *harriers* there is a very considerable variety—they may be said to be of all sorts and sizes; though, some years ago, the southern hound was generally considered as the only proper dog for the pursuit of the hare. The southern hounds are very deep-toned dogs, with thick lips, deep-flewed, and appear in every respect as like the talbot as possible, only smaller—like the talbot, the southern hound is remarkable for the excellence of his olfactory organs, and like him too, he possesses a very large head, whence he derives the faculty just mentioned. These hounds are slow in the pursuit—so much so indeed, that they have fallen into disuse. We are informed that they were formerly much in use in the neighbourhood of Manchester; and indeed something very nearly approaching the southern hound is still to be found in Lancashire; the hounds, for instance, in the possession of those celebrated characters, the Whitworth Doctors, are deep-flewed dogs, very much resembling the southern hound.

On the subject of harriers, after noticing the southern hound, the Rev. W. Daniel mentions as dogs calculated for the pursuit of the hare—"the fleet, sharp-nosed dog, ears narrow, deep-chested, with thin shoulders, shewing a quarter cross of the fox-hound." Now such jargon amounts to nothing—to talk of a quarter cross of the fox-hound, is very like the nonsense of a man who is profoundly ignorant of the subject upon which he affects to write; and I suppose what the Rev. Author intended to assert was, that in proportion as the harrier is removed from the southern hound his nose becomes sharp, his ears small, &c.

He also enumerates "the rough wire-haired hound, thick quartered, well hung, and not too much flesh on his shoulders." Here the same remarks will again apply,

as those we made in the last paragraph. The fact is, that there are rough wire-haired harriers, as well as rough wire-haired fox-hounds, bred no doubt from a cross with the water spaniel or the lurcher; and this is the amount of the difference or distinction.

The *beagle*, the smallest of the hound tribe, may be enumerated amongst harriers, as they are used for the pursuit of the hare; and indeed this is the only chase for which they are calculated. The beagle may be immediately distinguished, not so much from his diminutive size, as for the shortness of his legs, and the elongated form of his body; the beagle, in fact, may be justly considered as the dwarf-hound, though even beagles vary considerably in size as well as quality.

Beagles lately came much into fashion, and those of a very small size, sharp nosed and fleet, were preferred; but they are getting fast into disrepute from the circumstance of their not being able to hunt a cool scent; this has, however, arisen entirely from the manner in which they have been bred; as we have not the least doubt that beagles may be produced with as fine noses as the talbot.

In what manner the first cross was made from the talbot or blood-hound is not known; though it is tolerably evident it must have arisen from something of the greyhound or lurcher tribe, and the cross continued according to the judgment or fancy of the owner.

The late Colonel Thornton produced a pack of beagles so small that they were called lap-dog beagles, whose exploits were much celebrated through the medium of the diurnal and weekly press; and of the same kind were those of Colonel Hardy. This gentleman had a pack of these little dogs, consisting of ten or eleven couple, which were always carried to and from the field in a large pair of panniers, slung across a horse: small as they were, they would keep a hare at her shifts to escape them, and often worry her to death. But it was similar to that species of the chase, where a fox was hunted in Devonshire House Gardens: it might be endured as a novelty, but no one would wish to witness it a second time. The catastrophe attending this pack of hounds is laughable, and perhaps is a larceny *unique* in its attempt. A small barn was their allotted kennel, the door of which was one night broke open, and every hound, with the panniers, stolen; nor could the most diligent search discover

the least trace of the robbers or the stolen property.

"The north country beagle is nimble and vigorous (says the author of the *Rural Sports*, followed by the author of the *Sportsman's Cabinet*); he pursues the hare with impetuosity, gives her no time to double; and, if the scent lies high, will easily run down two brace before dinner. But it is only in a good day that these speedy hounds shew themselves; for, without the constant discipline of the whip, and perpetually hunting them down, it is impossible to make a good pack of them." We are at a loss to know what is meant by the *north country beagle*: the light, fleet, sharp-nosed harrier is often called the northern hound, in contradistinction, most probably, to the deep-flewed southern hound; and this would appear the true interpretation of the meaning of the two writers just mentioned. As to the light sharp-nosed dogs requiring the discipline of the whip, it may be taken for granted, as an invariable rule, that all light sharp-nosed dogs will be much more inclined to riot than deep-flewed dogs, on account of the inferiority of their noses, as, not being able to touch the scent, they are very apt to become unruly; and this in a more or less degree, according to the quality of their olfactory nerves.

Harriers may be bred in almost any form, or of almost any quality; and it is certainly advisable to breed them according to the country which they are intended to hunt. He that delights in a long chase, and to be up with the hounds all the time, will prefer the southern hound: their cry is a deep bass; and over greasy fallows, and in a bad scenting country, they will shew sport, where the lighter kind of harrier could not touch the scent. They pack well, from their equality of speed, and no sooner come to a fault than every nose is on the ground to recover the scent.

Where the country is bad, a remove or two from the southern hound will be preferable. It is difficult, however, to get fleet hounds to pack well: some are generally found to tail; but these tailing hounds, when the scent has been overran, are always the dogs to hit off the fault; and once more we assert, that these hounds will be found to have large heads.

In 1802, the Rev. R. W. Bamfylde sold his pack of harriers, consisting only of fifteen couple, for six hundred guineas.

*Otter-hounds* are but little seen, as otter hunting has of late years been but little in fashion. Any hounds may be trained

to hunt the otter; but the dogs generally used for the purpose are rough coated, bred most likely between the hound and the water spaniel; and, for tone or nose, may be bred precisely in the same manner as the harrier.

**HUMOURS.** All chronic disorders in the horse, arising from an impure state of the blood, are with the inferior classes in general denominated "humours."

**HUMBLES.** The articles so called are some of the internal *trimmings* obtained in breaking up a deer, which are always a perquisite of the keeper.

**HUNTER, THE.** We now come to the horse used for hunting; he is pre-eminently entitled to our notice, whether considered as to his breeding, his importance, or the princely amusement in which his persevering and spirited exertions are called into action. It is very well known, particularly to those who follow the hare, the stag, or the more noble diversion of *fox hunting*, that a very considerable alteration has taken place in the animal used for following the hounds. For nearly, if not quite, a century, the hunter may be said to have been in a state of progressive improvement, as the kind of horse formerly used for the purpose is now scarcely to be met with, and, when seen, is no longer capable of pursuing the amusement already mentioned, owing to the increased speed with which it is at present conducted. As the hound was rendered more fleet, it became necessary to increase the progressive motion of the horse also, so that, in a smart run with a fox, the old English hunter would be completely lost in a few minutes.

It is a maxim with sportsmen of the new school, (and an excellent maxim it is) that in a hunter as much blood and bone as possible should be united—you may thus acquire perfection, and it can be accomplished in no other way. Yet the task is more difficult than a first, or super-

## H U N T E R

ficial, glance of the business might seem to indicate, as, an union, sufficiently strong, of the qualities in question, is not very often to be met with ; or, in other words, thorough-bred horses, and particularly those of the best blood, are seldom possessed of sufficient bone to render them pre-eminently calculated for the chase ; and I am free to confess, that the very best hunters that have ever fallen under my observation, have been remarkably well and very highly bred, but yet not absolutely thorough-bred.

I have heard it remarked, that small bone with large sinew or tendon, is the union which gives to the animal possessing it, superior powers of speed and endurance ; but such an assertion can never be the offspring of reason and reflection, since a formation of this kind is rarely, if ever, to be found ; and, were it to be met with, inasmuch as it would form a sort of preternatural union, it would weaken, rather than add to, the powers of the animal which possessed it. Bone is the fundamental principle of strength ; it is the substance to which the tendon is attached, (and by which, indeed, both it and also the muscle is supported ;) and therefore the bone and tendon will be found, for the most part, in just proportion. Where much bone is seen, much tendon will be found also ; and where it happens otherwise, I should consider it a malformation, as a circumstance no way desirable, and consequently not to be recommended.

It is a common practise to convert thorough-bred horses, which, on trial, prove too slow for racing, into hunters ; but they seldom prove first rates, and have seldom strength sufficient to carry a common-sized man. When a horse has been trained for the course, his action is rarely calculated for a hunter ; he goes too close to the ground (is too much of a daisy cutter) to get well over rough, uneven ground. Light thorough-bred horses, I am well aware, owing to their superior blood, will struggle with uncommon energy and spirit ; but, in defiance of breeding, the light leggy racer cannot get through a heavy country—his physical strength is not sufficient to enable him to accomplish it. In training the racer, the animal is thrown forward, and taught to go as near to the ground as possible, for the purpose of increasing his speed to the utmost possible degree. The hunter's action should be the reverse of this, in a great measure ; it should, in fact, be lofty : and as the racer is generally a leggy light animal, the hunter, on the contrary, should be as bulky and as short-legged as possible. And, after all, one trifling remove from full-blood, and one trifling remove only, will be found in general the best method of breeding superior hunters. If, however, unquestionable full-blood be regarded as indispensable to the perfection of the hunter, the object in view is much more likely to be attained by keeping the animal altogether from the racing stable, and not put him to great exertion till he has acquired sufficient strength—till he has attained his fifth year. I am of opinion that a horse which has been trained for the course seldom, if ever, becomes an accomplished jumper ; and, indeed, the observation is equally as applicable here as in a number of other instances, namely, that a horse, to be perfect at his business (whatever that may be) should be trained and kept to it, and to it only.

## H U N T E R

A notion obtains general currency, at least in some of the north western counties, that the Irish horses make the best hunters; and I must candidly confess, that I have seen many (and possessed some) excellent hunters which claimed an Irish nativity. But, since Irish horses are neither better bred, nor better formed, than English hunters, we must look for their superiority, if indeed they possess it, to some other cause than the natural quality of the animal; and, on examination, it will be found to arise from the fearless manner in which they are ridden. A horse to become, and to continue, a good hunter, must be boldly ridden; but I would have them, at the same time, judiciously ridden also: in the latter quality our neighbours of the Emerald Isle are, in all probability, a little deficient; and hence so many of the Irish hunters will be found to have sustained injury. Many Irish hunters annually find their way into England, particularly through the port of Liverpool, few of which are free from blemishes. They are often impetuous in the field, owing to the mode in which they have been trained; but soon become tractable by a different method of treatment.

Having already observed that horses go well in all forms, so it may be said of the subject of the present article, that good hunters are to be seen in all forms; but as there is a peculiar conformation of the animal which is esteemed, from well-founded experience, as superior to all others, it follows, of course, that such is the form to be recommended.

From the speedy, laborious, and long-continued exertion which a hunter is called upon to sustain, it is abundantly evident, that his form and figure should constitute the essence, if possible, of strength and speed; and therefore, after having met with an animal possessing a sufficient share of blood or breeding for the purpose, the next thing to be considered is his form as indicative of the requisite qualities.—A knowing dealer remarked to me, that, in the choice of a hunter, the first point to be examined was the hock, (he was shewing me a hunter he had for sale, remarkable for the size of the hocks,) as it was vain to expect any horse to make a good hunter, unless he possessed good hocks. This is all very well, and, beyond all question, a hunter cannot have a better recommendation than good hocks: there are, however, other points and circumstances to be considered; and, instead of the hock, I think it quite as well, like Old Buckle, to commence our observations at the fore feet. If there be such a malformation of the feet as to cause lameness, or to impede, in any way, the animal's motions:—if, for instance, he was what is called *tender* (having the navicular disease;) or foundered, all other qualities, however excellent, are rendered nugatory. It is true, a hunter, with tender fore feet, as he goes principally on soft ground, will perform a day's hunting very well; but then, if the day should be severe, which is very often the case with fox hounds, the exertion which the horse has undergone produces inflammation or fever in the feet, he cannot feed, on account of the pain which he endures, and will not be in a fit state to go out again for several weeks:—consequently, a horse with bad feet should be cautiously avoided.

## H U N T E R

It is not, however, intended in the present article, to point out what may be termed the diseases of the horse, whether latent or otherwise, but to describe the form, proportions, and figure of the animal, in such a manner, and in language so plain, as to enable the uninitiated to form a judgment for themselves; and as the diseases and local defects will appear specifically under the proper distinct heads, we shall continue the immediate and legitimate subject of the present article.

As strength is so essential an ingredient in the composition of the hunter, it must be evident that a small or little horse cannot be well calculated for the purpose: and yet there is a medium to be observed, and the extremes should be avoided. As a little horse cannot possess sufficient power, so it may be justly observed, in the phraseology of the school, that an overgrown beast will “*tire himself—his own weight will kill him.*” Judging, from considerable experience, and an extensive field of observation, I have little hesitation in observing, that a hunter should not be much less than fifteen hands two inches high, nor much more than sixteen hands: this I should lay down as a general rule, subject to exceptions certainly, as will always be found the case. Great strength, as it has already been observed, is indispensable in the hunter; and although the requisite strength will generally be found in the height I have just mentioned, yet sometimes it happens that horses of extraordinary power are to be met with considerably under that standard. Of this I have seen many remarkable instances. The celebrated pony hunter, the property of Mr. Coke (nephew to Mr. Coke of Holkham) and well known a few years ago at Melton, was under fifteen hands, but nevertheless possessed extraordinary powers; his form, though handsome, might be said to be equally extraordinary; and as there can be no effect without a cause, so the animal in question, on examination, was found to possess such uncommon bulk that he was in reality as large, if not larger, than the generality of hunters.—A few years back, I saw a dark brown horse in the possession of a person named Harrop, who resided at Liverpool, scarcely fifteen hands high, but possessing uncommon power, and of course uncommon bulk. He was larger and more powerful than Mr. Coke’s pony hunter; both animals were handsome, but not so remarkable for beauty, abstractedly considered, as for that symmetrical union of parts as would seem to approach perfection as nearly as possible: as hunters they had no superiors. The dark brown horse just mentioned (called, I believe, Robin Put) passed from the hands of Harrop into those of one Powell, a dealer; Mason, the dealer, purchased him from Powell, when he passed into the hands of Sir H. Goodricke; and I believe was ultimately killed by some accident in Leicestershire.

A grey horse belonging to Sir John Kaye may be placed in the same class. He is not fifteen hands high, but an animal of such bone and conformation as would seem to indicate every thing which could be desired in a hunter: moreover, he is thorough-bred, and, to make use of a common phrase, possesses the strength of a wagon horse. He is the most deceptive horse which ever fell under my

observation. In these cases, it must be recollected, that, though the animals were considerably under what I consider the standard of a hunter, they were, nevertheless, what might justly be considered as large horses.

If we observe the principles of progressive motion, in reference at least to quadrupeds, and particularly to such animals as are remarkable for the celerity of their movements, we shall perceive that the fleetest of them are peculiarly calculated for speed by a combination of parts, which is truly surprising, almost, as it were, in a mechanical point of view. Animals of the deer kind are remarkable for swiftness, and their form is admirably calculated for the purpose: they are much lower before than behind; their fore legs are short in proportion to their hind legs; and their bodies so formed that the viscera are placed forward, thus leaving great scope for the free and extensive action of the hind legs, which, of course, are mainly instrumental in giving an increased impetus to the animal's progressive motion. Pursuing the same train of reasoning, let us next regard the greyhound, which offers a further and stronger confirmation of the hypothesis: the greyhound is smaller than the stag, but swifter, and this superior speed arises, beyond all question, from the superior combination of his form; and if those who feel sufficiently interested in the investigation, will take the trouble to examine, they will find that those greyhounds which have rendered themselves celebrated by outstripping competition (such as the celebrated Snowball, for instance;) have been equally remarkable for a low-dropping chest, an uncommon length of hind legs,\* and commensurate space for their sweeping action. The most striking proof, however, of the correctness of this position remains to be stated:—I allude to the hare. This animal is the fleetest quadruped in nature, that is, when her size is taken into consideration. The hare is generally found to weigh from six or seven to ten or eleven pounds, though hares seldom reach the latter weight:—the hare is swifter than the stag, whose weight cannot be much less than ten times that of the hare:—she is as fleet, or nearly so, as the greyhound, which is four or five times larger! Whence, then, arises this extraordinary celerity of motion? We must look for the cause in the striking peculiarity of her conformation. Every person that has ever noticed a hare could not fail to have been struck with the great apparent disparity between the length of the fore and the hind legs; with her very low-dropping chest, the absence of heavy viscera at the posterior part of the abdomen, and the amazing breadth and strength of her loins. It will easily be perceived, that the peculiar structure of her legs enables her to cover a larger space in her stride than any other animal (speaking comparatively), while the uncommon strength resulting from her loins, thighs, and generally from the combination of her body, give her the power to repeat her amazing strides with incalculable rapidity.

In the purchase of a hunter, therefore, these principles, or this

---

\* Similar remarks are applicable to such racers as have been remarkable for speed, and to Eclipse in particular.

hypothesis, should be kept in view. I do not mean to assert, that a horse is to be met with formed precisely in the same mould as any of the animals just enumerated, but the principle is precisely similar, and the same reasoning will apply in both cases. Beauty is a term which, in most cases, must be applied relatively; for instance, a horse may be very beautiful as a hunter, without impressing upon the mind the idea of a beautiful hack; and therefore the form of the horse which we are to consider under the present head, is that best calculated for following hounds. Having stated my notions upon the principles of speed, a quality essentially necessary in a hunter, I have further to remark, that, as a horse of this description has to traverse spaces where jumping as well as galloping becomes indispensably requisite, it will be advisable to look for an union of parts the best calculated for the combined object which we have in view. As it has already been shewn that speed mainly results from a peculiar formation of the hind quarters, so, on examination, it will be found that it requires more than ordinary strength in the same parts to enable a horse to distinguish himself as a jumper. In jumping,\* the spring must arise altogether from the hind quarters; and therefore, in a hunter, I should not only look for strong hocks, but long muscular thighs, wide spread quarters and loins as strong as possible, moderately ribbed up; rather round, than narrow, in the barrel; back not too long; low-dropping chest; bony, and muscular in the arm; strong knee; short from the knee to the ground; strong declining shoulders, not too fine at the top; if the neck be well set in to the shoulders and finely formed, the head well set on and handsome, so much the better; they contribute much on the score of beauty, and cannot operate as a drawback on the goodness of the animal; a bold, full, clear eye; broad, rather than narrow, forehead; nostrils wide. Horses, whose shoulders taper very finely to the top, are apt to become foundered, though I have seen many excellent hunters with shoulders of this description. Having previously spoken of the feet, I need not repeat the remarks in this place.—Moreover, a hunter should stand over a considerable space.† It will frequently happen that a short backed horse will stand thus, owing to the sloping position of his shoulders, and his quarters being well set in:—horses of this formation are well calculated for the business. A leggy horse cannot be recommended for hunting. Observations on the quality of the eye, as they are of general application, have appeared under a distinct head. See EYE.

Colour I regard as a matter of indifference, since good horses are

---

\* It is asserted by many persons, that the act of jumping (leaping, according to the phraseology of the old school;) is nothing more than an elongation of the gallop; or, in other words, that jumping is merely an extension of the gallop. I cannot agree exactly to this. In galloping, all the feet, I think, are not from the ground at the same time; but they are obviously so in jumping. The horse, also, presents very different appearances in the two positions.

† He should stand straight also, turn out his toes neither before nor behind. Good horses, it is true, are sometimes met with of this formation, but it never can be a recommendation.

to be found of all colours; and, as the old saying expresses very truly, “a good horse cannot be of a bad colour.”—However, as far as relates to beauty of appearance in the field, a dapple-grey or golden bay is to be preferred.

A horse intended for a hunter, if put to very severe exertion at an early period of his life, is frequently ruined, or so far injured that no dependance can be placed on his future exertions. It causes founder, debility, and a train of evils which it is impossible to enumerate.—A horse will rarely become a perfect hunter before he is seven or eight years old; and with proper treatment, if his constitution be vigorous, he will generally be enabled to perform his business till he attains the age of sixteen, or perhaps twenty.

**HUNTER, MANAGEMENT OF THE.** Some remarks respecting the management of the hunter have already appeared under the head “CONDITION;” but they are, in a great degree, of general application: we have therefore deemed it necessary to enter more particularly into the subject in this place.

*On the treatment of the Hunter, both summer and winter; with miscellaneous observations.*

The subject of summering the hunter has, of late years, occupied the attention of the sporting world in a more than ordinary degree: the old and general system of summering at grass has been vigorously opposed by a very active minority, who have endeavoured to prove, that summering the hunter in the stable is infinitely superior to the old method of summering him in the open air; and that, in fact, the latter is generally attended with the most disastrous consequences. But it would appear to me, that the advocates of the different systems, in the heat of argument, have entirely overlooked that which ought to constitute the fundamental principle of each—I allude to the constitution, or physical habit, of the horse,—a subject which it is highly necessary to bring under consideration.

Although the stable system is generally denominated the *new system*, it is not quite so modern as this term would seem to imply, since the sportsmen of the old school were divided in opinion on the same subject; or, at least, the grass system was called in question by a minority of them, much in the same way as it has been for the last few years by modern sportsmen. An author, whose notions on hunting appeared in the year 1733, thus speaks of the treatment of the hunter. “As to all matters of feeding, physicking, airing, &c. I refer you to the more

expert grooms, or the learned doctors of the hammer and pincers; but as my way of ordering my steeds is to consult use rather than ornament, I always keep them in the open air (unless the night after a hard chase); I allow them two or three acres of pasture to cool their bellies and stretch their limbs, with a warm hovel to shelter them from a storm; a rack and manger, with proper provisions, to keep them in heart; and a fresh spring of water in the same field to quench their thirst. I have known a gelding, with this regimen, to be sound, fresh, and in full vigour, after ten years of the hardest hunting; I dare promise him that shall try it, to find such an one as far beyond the fine cloathed, thin skinned courser (*cæteris paribus*), as a rough ploughman is fitter for business than a soft handed beau.” I quote this merely to shew the opinion of a sportsman of the last century, not as a system that I would recommend; as I am willing to suppose that, as most arts and sciences have been in a state of progressive improvement, the treatment of that noble quadruped, the horse, has not been forgotten in the general march of the mind.

The eloquent Beckford, whose “Thoughts on Hunting” made their appearance at a more recent period, thus expresses himself on the subject of summering the hunter:—“After a long and tiresome winter (says he) surely the horse deserves some repose. Let him then enjoy his short lived liberty; and as his feet are the parts which suffer most, turn him out into a soft pasture. Some there are who disapprove of grass, saying, that when a horse is in good order, the turning him out undoes it all again. It certainly does. Yet this, at the same time, I believe, that no horse can be fresh in his limbs, or will last long, without it. Can standing in a

hot stable do him any good? and can hard exercise, particularly in the summer, be of any advantage to him? Is it not soft ground, and long rest, that will best refresh his limbs, while the night air and morning dews will invigorate his body? Some never physic their hunters; only observing, when they first take them up from grass, to work them gently: some turn out their's all the year. It is not unusual for such as follow the latter method to physic their horses at grass; they then are taken up, well fed, and properly exercised, to get them into order: this done, they are turned out for a few hours every day when they are not ridden. The pasture should be dry, and should have little grass: there they will stretch their limbs, cool their bodies, and will take as much exercise as is necessary for them. I have often remarked, that, thus treated, they catch fewer colds, have the use of their limbs more freely, and are less liable to lameness than other horses. Another advantage attends this method, which, in the horses you ride yourself, you will allow to be very material:—your horse, when once he is in order, will require less strong exercise than grooms generally give their horses; and his mouth, in all probability, will not be the worse for it."

The Earl of Pembroke, in his "Military Equitation," observes, "Horses should be turned loose somewhere, or walked about every day when they do not work, particularly after hard exercise:—swelled legs, physic, &c. will be saved by these means, and many distempers avoided."—He further observes—"it is a matter of the greatest consequence, though few attend to it, to feed horses according to their work. When the work is hard, food should be in plenty; when it is otherwise, the food should be diminished immediately, the hay particularly."

These quotations are given to shew the opinions of men of sense and reflection, who had studied the subject at a period when it was not so well understood, nor had been so thoroughly investigated, as at present; and when the short, beautiful, glossy coat, so indispensable in the present day, was but little regarded. A horse which is exposed to a cold atmosphere will be rough in his coat; a considerable degree of warmth (to say nothing of good grooming and good feeding) being absolutely requisite to give the sleek silky coat now so highly, and so justly, esteemed.

In regard to the much-agitated question, *summering the hunter*, I am decidedly of opinion that what ought to constitute the leading principle, namely, the *constitution and state of the horse*, has not been sufficiently regarded in the discussion of the question; and therefore, upon due consideration of the subject, it will perhaps be found that the advocates on both sides have somewhat overstrained the point. The true Arabian horse, from whom we have, in a very great measure, derived our hunters, at least our modern hunters, is an animal whose constitution seems to require a very considerable degree of atmospheric warmth: to this he is constantly exposed in his own country, where he is remarkable for his beauty, his spirit, and vigorous perseverance; and therefore, I am of opinion, in the treatment of our hunters, we should keep this steadily in view.

If a horse be regularly hunted throughout the season, he must be fortunate indeed, if he do not receive many bangs and bruises about the feet; in fact, his legs and feet are what must necessarily suffer the most during his laborious occupation; and it is very fair to presume, that, at the end of the hunting season, he is something "worse for wear," is suffering from the bangs and bruises already noticed, as well perhaps as from the straining of the tendons, and other incidents to which the hunter is peculiarly liable: added to which, the animal has been highly fed, and throughout the season may be said to have been kept in a state of continual excitement. Now, the question is, which is the method, under such circumstances, to re-invigorate him, and restore his constitution to its wonted or requisite state? There are many persons, I am very well aware, who would prefer the stable to the field; but I am free to confess, that I am not one of those. Under the circumstances already set forth (and generally speaking, they will be found to apply to hunters) I would turn the horse into a dry, but not hard, pasture, where he might crop the early spring grass, which would cool his body, and thus allay the excitement under which his system had been kept for many previous months; while his feet and legs (perhaps in some degree inflamed) would derive every possible benefit from the coolness of the ground—advantages which he could not derive if kept in the stable.—In thus turning the horse out at an early period, I do not wish it to be understood

that I would suffer him to remain out during the night; on the contrary, I would have him housed till such time as the weather was sufficiently warm, and the season sufficiently advanced, so as to remove all doubt as to his sustaining any injury from remaining abroad, exposed to the cold air.

During the hunting season, the faculties and powers of the horse may be said to be kept constantly on the stretch; and consequently, at the end of that period, they must require relaxation; for which the stable system does not, in my opinion, appear well calculated.

And, in speaking of summering in the field, I must here observe, that, as at the early period of the summer, I would not allow the horse to remain out during the night, so, as the season advanced, the weather became hot, and flies troublesome, I would take him into the stable during the heat of the day.

If a horse happens to be very short in the neck, with long fore legs, the pasture in which he is placed, should not be a level flat; on the contrary, it should be hilly or undulated; or what an old sporting friend calls "a give and take pasture," as the horse will thus feed much easier.

When a horse happens to be tender in the fore feet, summering on a soft pasture cannot be otherwise than infinitely superior to summering in the stable. In fact, the feet of a horse are very apt to contract by standing in the stable:—if he is to be summered in the stable, some artificial precaution must be adopted to prevent the contraction; otherwise the circulation in the feet, from the heat and dryness of the stable, will be obstructed, and the hoof or heel will consequently contract.

Where a horse is tender before, the pasture should be as soft as possible; and many marshes are to be met with which are very well calculated to answer the end in question. I should be careful, however, to choose such marshes as were not remarkable for rich or luxuriant pasturage; I would have the grass hard and scanty rather than otherwise, since I am inclined to think the reverse of this is apt to produce that unpleasant disease in the horse, emphatically known by the name of *roaring*.

In conversing upon this subject with that intelligent gentleman, Mr. Scarisbrick of Scarisbrick Hall, near Liverpool, in the early part of the year 1827, he observed that his paddocks, (four in number) upon which we were then walking,

some years before had been well manured, under the idea of increasing and rendering the pasture more luxuriant, since which, however, they had repeatedly produced roarers; which he attributed entirely to the circumstance just noticed, and, I make no doubt, justly.

Light, hard, benty grass is the best calculated for horses, and for hunters and all horses with any pretensions to breeding in particular. It is true, by turning a hunter out to grass, you lose his condition, and this is one of the principal arguments advanced against it, by the advocates of the stable system; but surely it is no difficult matter to take the horse up in time, so as to place upon him that firm elastic muscle so necessary in a hunter. And, indeed, if, while at grass, corn be given to the horse, his condition will suffer very little; but I do not think this necessary, since, if he be taken up two or three months before the hunting season, and properly fed, properly exercised, and properly groomed, he will be completely fit for his business; and, what is more, he will be, as it were, a new horse.

Where a hunter has done but little work, he will sustain no injury, perhaps, by being summered in the stable, supposing him to be perfectly sound; but his feet, nevertheless, should be particularly attended to, or they will be very likely, I think, to contract. However, if such a circumstance do not happen, I do not mean, for a moment, to deny that such a horse will come out at the commencement of the hunting season every way calculated for his work.

The beautiful bloom of a horse's coat may be better preserved in the stable than in the field; and from this and some other minor circumstances, perhaps, the advocates of the system of summering the hunter in the stable, hastily insisted upon the superiority without any qualification; but experience soon taught them that, in the stable, the feet of the horse, required more attention than they had at first suspected, and a clay house or shed was then mentioned; that is, a few cart loads of clay were to be placed under a shed, to be kept well moistened with water, and in this wet clay, the horse's feet were to be placed for several hours each day; and shortly afterwards an inclosure, allowing sufficient room for the horse to move about and exercise himself, was recommended; while, at the same time it was admitted, that green food, or soiling

in the stable, was indispensable. Now, what does all this amount to, but that it is a troublesome and expensive method of doing that which may be better accomplished by a run at grass in the manner I have already described.

It may be also very justly observed, that, in the treatment of the hunter, his constitution should, in the first instance, be duly considered; since, it will be found that some horses will do better in the stable than others, during the summer; and, in this the judgment of the owner, or of those in whom he confides, must decide, since it is impossible to lay down any precise rules without a previous knowledge of the identical cases.

I wish to be particularly understood, that, although I am an advocate for a run at grass, I would by no means recommend an unqualified summer's run. I would give the horse the early spring grass, if possible (as I have already observed), but I would not suffer him to remain out at night till the weather became sufficiently warm; when he should be sheltered during the heat of the day from his tormentors, the flies.

And, after all, upon a considerate view of the case, the two systems will be found to approximate each other, since, if the pasture be scanty, and corn be given at grass, the advantages of condition are preserved in a great degree; while, by the stable system, the use of the clay shed may, perhaps, preserve the feet from contraction. But I feel a perfect conviction, that, by the latter method, the constitutional vigour of the animal becomes much sooner exhausted; he may be said to experience a premature old age; or, in other words, he is much sooner worn out; since he requires much more medicine, and is kept, it may be said, in a constant state of excitement. When a horse is summered in the stable, regular exercise is, of course, absolutely necessary.

As a proof of the re-invigorating qualities of a run at grass, we have only to look at any battered and jaded horse, and particularly at such as are employed in stage coaches. When these, for instance, have been worked to a "stand still," as it is called, their legs and feet battered to pieces by the hard road, a few weeks' grass is the remedy, and perhaps the only remedy; after a few weeks, they come up again, "quite new horses," able to proceed with their work; and thus nature, in a short period, accomplishes that, which would be very tedious to bring about in

the stable with all the assistance of art, to say nothing of the much greater expense attending it: in many cases, the object could never be accomplished in the stable.

We have been told of late years, by the strenuous advocates of the stable system of summering the hunter, that grazing the horse for the summer is very apt to produce roaring; but this is one of those sweeping declarations that, to be properly understood, requires elucidation. If a hunter, after being kept in a very warm stable during the season, and highly fed upon hard meat, be improperly turned out, it is no matter of wonder if he should become a roarer: if the transition be sudden, the horse will take cold, and, if neglected, is very likely to come up a roarer. The animal should be prepared for so great a change by degrees, nor should he, in my opinion, be suffered to remain out during the night till he has been some weeks at grass, unless indeed the season be advanced and the weather warm. The fact is, that the grass system, like all other systems, is liable to abuse; and thus the glaring improprieties of the groom are placed to its account; though I feel perfectly convinced, that no danger of roaring from summering the hunter at grass is to be apprehended, provided the horse be properly prepared for the change.

A horse, which is intended to undergo the laborious exertion of the ensuing season's hunting, if summered at grass, should be taken up in good time; as, if he be suffered to remain out till the approach of cold weather, his coat will be apt to stare; nature will not fail to guard herself against the approaching change of the atmosphere by a longer, thicker, and consequently warmer coat; which, however well it may be calculated to protect the animal from the severities of our chilling climate, has a very unsightly appearance by the cover-side, to say nothing of another serious inconvenience, after a hard day's hunting—I mean *drying*.

On coming up from grass, it is the general custom to put the horse through a course of physic; and in most cases this is practised without the least reference to the animal's constitution, at least in an individual point of view. Any person capable of reflection will easily perceive that horses, like human beings, vary very considerably in constitution, and consequently, either as it regards physic or food, or exercise, should be treated accordingly.

I am induced to suppose that some hunters, on being taken up from grass, require very little physic, though I am very well aware that it is the general practise to put the horse through a regular course of medicine. On speaking to an old sporting friend on this subject, (a very strenuous advocate for physic) he remarked, that such a plan could do no harm; that physic never hurts a horse; and therefore fortified himself under the idea that, though the horse might stand in no need of physic, yet, from the administration of it, nothing injurious could result: but this is a doctrine to which I cannot subscribe, and which, I am inclined to think, will not endure the test of reasonable investigation. It must be admitted that physic excites an unusual and indeed an unnatural action of the animal system; and therefore, if administered, when not called for, must be injurious; if often administered, under such circumstances, cannot fail to weaken and impair the animal organization—cannot fail, in fact, to induce premature decay.

If a horse, when taken up from grass, do not improve in his condition and appearance as he ought, he, most likely, is in want of physic; he may be plagued with worms, which, of course, it will be highly necessary to remove; and this purpose is best effected, according to the notion of some, by administering linseed oil; and I am inclined to be of this opinion, since this, as well as several other *vegetable* oils (and perhaps vegetable oils in general), are the very bane of the insect and worm tribes. However, as I never feel myself justified in attempting to administer remedies, where my knowledge must be very imperfect, so I must recommend the same system:—I might feel no hesitation in bleeding a horse, or giving a simple dose of physic to him; but where I had a remote suspicion of approaching danger, or did not understand the case, I would call in the assistance of a professional man, with the least possible delay. At the same time, I have to observe, that, though I should be thus ready to employ a veterinary surgeon, I would not trust so valuable an animal as a favourite horse to his entire controul, unless I had the utmost confidence in his skill. A veterinary surgeon should possess sound sense and also acute perception—such a man would form his practise upon the principles of reason and true philosophy—I should be inclined to place implicit confidence in such a person, and rest

satisfied, whatever might be the result.

As I am come to speak of the hunter on being taken up from grass, I must observe, that as I recommended turning him out by degrees, as it were, so, in taking him up, I would not have the rigid and regular stable discipline inflicted upon him immediately. This change, like the others, should be brought about by degrees. For instance, in the first place, the stable should be cool, his cloathing trifling, his corn less than the usual stable allowance (and, of course, increased by degrees), and his exercise gentle. These matters should proceed in judicious progression till the required condition is accomplished. The perfection of condition must be to get as much firm elastic muscle upon the horse as possible, devoid, however, entirely of fat, since even the smallest quantity of the latter must be a drawback upon the animal's powers of speed and endurance. Therefore, if, when I took the horse up from grass, I found that he went on well, I should proceed without much physic; but if his coat appeared *penny*, or he otherwise indicated imperfect health, I should deem physic indispensably necessary. I have already remarked that the horse is subject to worms; but it is a matter of doubt as to the manner in which these vermin are generated—a gentleman whose opinion respecting horses I very much value, supposes that the embryo of the worm is externally deposited, and makes its way into the stomach or intestines through the pores of the skin. See WORMS.

It frequently happens that the feet of hunters require more than ordinary attention in the stable. If it be necessary to stuff the feet of a hunter, tar and clay mixed, will be found, generally speaking, to answer the purpose; tar mixed with hog's lard is perhaps better in many cases; and crushed linseed mixed with water has been lately brought into use. Goodwin, in his excellent work on Shoeing, observes, (speaking of the hoof of the horse) "It is familiar to every person, who has paid attention to the nature of horn, that it readily absorbs water, and that a few hours' immersion softens and renders it pliant. When subject to the heat of stables and fermented litter, evaporation takes place so freely, that not only the little moisture which may have been absorbed during the day, when at exercise or work in wet weather, is quickly evaporated on returning into the stable, but also a great

portion of the moisture which has penetrated the hoof from within. Thus, if no means have been devised to counteract these effects, hoofs soon become hard and brittle. It is therefore an object of great moment to bring horses' feet, when in the stable, as near to a state of nature as can be accomplished without much inconvenience. For this purpose I recommend two pieces of Bath coating, or any other coarse cloth, cut to the precise form and size of the hoof, and stitched together with a leather lace at each end long enough to go once or twice round the foot. It should be made quite wet, and be tied round horses' feet when dressed and clean. I also fill their feet with crushed linseed, mixed with water, and made of the consistence of stiff mortar. I have found most advantage in using crushed linseed without any of the oil being taken out of it, as a foot stopping in preference to any other." Cow dung, though used for stopping, has a tendency, it is said, to destroy the texture of the frog.

Once a week, it is supposed, is sufficient for a horse to go out with foxhounds; but there are many horses that will come out more frequently, if judiciously ridden. Of course, the day the horse is intended for hunting, he should not receive his usual allowance of food: on the contrary, one small feed of corn only should be given him at an early period of the morning with a few gulps of water—no horse can go well on a full belly; at the same time, the stomach should not be absolutely empty. On returning home after the exertions of the chase, his treatment should be regulated by his state of exhaustion or otherwise. If the horse be what is called *over-marked* (rendered feeble by excessive fatigue) a dram of tartar emetic may be given with advantage, and it may be found necessary to bleed him. However, speaking generally, I would, as soon as the horse reached home, after a hard day's hunting, give him a warm mash, composed of linseed, bran, and oats; and on all occasions, (at least where the horse has undergone a hard day's work) should prefer getting something nourishing into his stomach, to rubbing him dry, &c. which operation I have often seen grooms compel their horses to undergo before they have allowed them to eat. Where a moist warm mash is given (and it should be ready to be put in the manger, if possible, as soon as the horse comes in) the horse will not require gruel, or indeed water till he is

perfectly dry and cool. On returning from hunting on ordinary occasions, having a few miles to ride home, the horse having become cool and dry, I have let him drink a few gulps of water at some stream or convenient place, as I passed along—and trotted on: this indeed is my general practise, unless the exertions of the day have been extraordinarily severe, and I have a considerable distance to ride, when I give him some oatmeal and lukewarm water at the first house where I can procure it. Some persons prefer *flour*, instead of oatmeal on such occasions, on account, as they say, of the purgative or scouring quality which the latter possesses:—On this very account I prefer it, since, beyond all question, the best results may frequently follow its administration to the horse under such circumstances, and particularly in preventing or counteracting any tendency to inflammation.

#### HUNTERS' STAKES, AND COCK- TAIL RACING:—

We copy the following from that highly interesting little book, *BROWN'S TURF EXPOSITOR*.—Horses which appear as racers, and are understood not to be thorough-bred, are, in the common language of the turf, denominated *Cocktails*. They run for hunters' stakes, and also for what are called half-bred stakes; nor indeed are they debarred from running for regular plates, &c. for which, however, they seldom enter: though instances are not wanting where they have beaten acknowledged thorough-bred horses, and those of a fair description, or perhaps a little above the average of what may be called plate horses; as an instance, I give the following:—at Knutsford Races, 1827, *Miracle*, a cocktail, belonging to a man named Hudson, was entered for one of the plates. Three started, *Miracle*, *Orthodox*, and *Vesta*; the plate was won by *Miracle* after three well contested heats!—Yet *Miracle* raced under the description of a cocktail!

The fact is, a number (the greater part perhaps) of these cocktails are *thorough-bred horses*; and of all systems of swindling and fraud, there is none more contemptible and disgusting than cocktail racing. To say nothing of Tom Paine and several others, which have now disappeared, who, let me ask, could look for a moment at Brother to Hexgrave, The Tartar, Mr. Fry, Agnes, Judy Nicholson, and Sawney, and others, and suppose they were not thorough-bred? Let us look at the performances of the above-named

cocktails, and we shall be convinced that they are not only thorough-bred, but as well and almost as highly bred as possible. A real cocktail cannot bear the training even, which these horses have undergone; to say nothing of the powers of *continuance* which they have displayed, a characteristic so utterly inconsistent with the very nature of a horse with a taint in his pedigree: and indeed of which a real cocktail is absolutely incapable. If a real or genuine cocktail be put into training and treated the same way as a thorough-bred horse, he will, in a short time, refuse his corn, and consequently his training must cease. He is absolutely unable to endure the severe exercise to which thorough-bred horses are subjected, and refuses to feed. A cocktail can neither do the work nor feed like a thorough-bred horse.

Speaking upon the subject of cocktails with Mr. Pierse, the enlightened trainer, who resides at Belleisle, near Richmond, Yorkshire, he observed, that he had once a cocktail in his stable belonging to a gentleman of the name of Yates, who entertained a very favourable opinion of the capacity of his horse. The animal was high spirited and fretful, and the first time a lad was placed on his back for exercise, he ran away for the distance of some miles on the high road till he was stopped by a turnpike gate. However, he was taken to the ground and exercised several times, till he gave the usual symptoms of a mixture of base blood, viz. loss of appetite, and alarm at the sight of the moor where the exercise ground is situated: so great indeed was his terror of the latter, that it was found impossible, or at least unadvisable, to take him to it, or even to let him see it. What was to be done?—Mr. Yates, as I have already observed, regarded the horse as far above the common class of cocktails, and would have heard with much regret that he would not endure training. The best mode would be to bring him out in good condition to the first race, which, if short, he perhaps might win; and the system of training adopted was placing a lad on his back and exercising him round the stack yard, close to the stable. He was thus made to appear in tolerable condition. He was brought out at Lancaster, run for the half-bred stakes (which happened to be a short distance, for which he might be said to have good speed) and won. Mr. Yates was in raptures; but after some conversation with the elder Pierse, that gentleman was induced to sell him for

three hundred guineas, which were offered in consequence of his winning the stakes just mentioned, handsomely, having, very luckily, what may be called nothing to run against him. However, being placed in another trainer's hands, less acquainted with the nature of the business, and who attempted to train him in the regular way he was never afterwards able to run. Mr. Pierse finished the story by remarking, that no consideration should ever induce him to train another cocktail!

A horse of this description can race only in a certain way; no true cocktail can maintain a long contest against a thorough-bred horse; he may go as fast perhaps for a short distance, but he cannot continue the struggle for any considerable length. Hence those conversant with the business can never be much mistaken respecting true cocktails. If the animal be a genuine, true-bred cocktail, and is forced to encounter long or repeated struggles, nature denies the power of performance:—*out comes the black mare!*—the taint in the pedigree is too manifest to be mistaken. But many of the cocktails of late years, and particularly those of the present day, have been able to train, to go from race to race, and run as often as any acknowledged thorough-bred horses in the kingdom; and have not only been remarkable for speed, but for uncommon powers of continuing the struggle. Let us look for a moment at Gossoon, Fitzjames, Miracle, and Tawpy; the last in particular possessed, in the greatest possible perfection, the most distinguishing characteristic of the purest blood, namely, extraordinary capacity for endurance. These four *cocktails* have left the turf; but they have been succeeded by half a dozen others, whose claims to purity of blood are equal, if not superior, to their predecessors, at least, if an opinion is to be formed from their performances.

A person unacquainted with the nature of cocktail racing might reasonably ask—how can it happen that thorough-bred horses are brought out as cocktails, when certificates of pedigree are rendered indispensably necessary for the purpose of qualifying them for the stakes in which they appear? In order to answer this question satisfactorily, a little prefatory examination, or rather elucidation, becomes requisite, that we may arrive at a complete exposition of the business. In the first place, let us just glance at the part of the kingdom whence these more

than suspicious cocktails emerge. It is generally from the north, or more geographically speaking, from the northern part of the north-western coast, and the business, in its earlier stages, is brought about in a manner, or upon a system, varying according to circumstances. Let it not be forgotten that the spot is well-selected for the purpose, and shews at once the perspicacious calculation and uncommon foresight of those who figure in these nefarious transactions. A horse and mare became necessary for the purpose:—indeed, two horses and two mares are often rendered necessary in order to accomplish the contemplated fraud as impenetrably as possible. The men who breed these suspicious cocktails are persons who can practically perform the necessary operations of the stable, and therefore on many occasions stand in need of no assistant who might bear witness of the sinister transactions. Ambo, once belonging to Sir W. Wynne, or rather to Sir W. Wynne's brother, became the property of several other persons, after the conclusion of his racing career; and, while in the hands of one of these people, he was kept for some time in a loose sort of old building, situated at a place in Cheshire, convenient for the purpose. The owner of Ambo had another stallion, with some pretensions to blood (something more than half-bred;) which covered publicly. He had a mare also suited to his purpose, thorough-bred, which he gave out had been put to the half-bred horse, but which in reality had been put to Ambo. But I never knew what became of the foal; as the fellow, (very suspicious, as such fellows generally are) contrived to get it completely away; and although I was never able to trace it, I have not the least doubt, it raced as a cocktail.—This circumstance took place not exactly in that part of the kingdom remarkable for producing suspicious cocktails, yet, that the position is correct may be easily perceived, if we consider, for a moment, whence came Tawpy, Brother to Hexgrave, Miracle, Mr. Fry, Sawney, Agnes, &c. &c.

The schemes put in practice by the breeders of these animals are various: sometimes, it is contrived to have two mares to bring forth as nearly at the same time as possible, and the foals are changed:—it is a very well and generally known fact, that a bitch will suckle strangers—a mare, it seems, with proper management will do the same. Sometimes

foals suddenly disappear—are given out as dead, and are brought on the course as cocktails, under a studiously prepared, but false, pedigree. The persons concerned in these transactions are men of a particular *caste*:—and, if I am not mistaken, the very man who introduced Tom Paine as a half-bred horse, is at this time the owner of a *first-rate cocktail*.—The manufacturing of pedigrees is an art or science in which also these men excel: it is true, the workmanship is clumsy, and always presents an awkward appearance; yet it passes. Indeed, a pedigree, regularly supported by a succession of oaths, if necessary, however false, is not easily disproved—in fact, the irrefragible proof is, for the most part, impossible, though in almost all these cases an unqualified conviction is indelibly impressed upon the mind of its gross and utter falsehood!

Then, again, the appearance of a horse is sometimes altered, and he is taken to a distant part of the country to run as a cocktail. A man, at present residing upon the north-western coast of the kingdom, aware of a fine thorough-bred horse having been brought into that part of the country—a horse too of uncommon power, and consequently able to carry weight, contrived to meet the owner of him prior to the covering season, *for the purpose of feeling his pulse*. The gentleman who had purchased and brought the horse into that part of the country was most superlatively ignorant of the art and mystery of manufacturing cocktails, and therefore when he met the proficient in the science, he had not the most distant idea of the object in view. After a few preliminary but indifferent observations, *Cocktail* (that name will serve to distinguish the *knowing one*;) said, “Your horse would win many of the heavy stakes in the kingdom.” The gentleman did not know that what are called *heavy stakes* are run for by horses understood not to be thorough-bred, but supposing that the carrying of a great weight was intended, very promptly replied—“I dare say he would, as he is one of the strongest horses in England.”—*Cocktail* immediately conceived that the owner of the horse understood the intended business, and would not hesitate to *come into it*; he therefore continued—“But we must *make him a pedigree*.” “There is not the least occasion for that (said the owner) the horse has an excellent pedigree.”—“O! but it won't do (said *Cocktail*); he must be made to appear

not thorough-bred." "That can't be, as the horse has raced, and is very well known." "Never mind that; I can easily procure him a *proper pedigree*; I could also get one of his legs painted, and a little more hair placed in his tail, and then no one will recognise him!" Here the conversation ended, and the business also; the owner turned away.

Whatever might have been the original intention of cocktail racing (and I have no doubt it was very laudable) it has become a regular and well-organized system of swindling and fraud. It behoves every gentleman and man of honour, connected with the turf, to discountenance it; and if stakes "*for horses not thorough-bred*" cannot be immediately expunged from every race list, a salutary check may easily be put upon it by weighting the winners in such a manner as could not fail to bring them to the proper level. Weight must and will always *tell*; and by this means an effectual *bridle* would be placed upon these nefarious cocktails at the commencement of their career. Even in regard to the age of these suspicious cocktails, that is often rendered a doubtful circumstance, as all the trickery and cunning of the men who own them, are put in practice to accomplish their purpose in this respect. From information which I have no reason to doubt, a cocktail from the north, which has repeatedly won during the present season (1829) has been running as a year younger than the correct age; added to this also, little doubt can exist of the animal being as thorough-bred as any racer in the kingdom. Moreover, to say nothing of the immediate and obvious turpitude of the system of cocktail racing, it is productive of continual and never-ending disputes.

HUNTING. See CHASE.

HUNTING CAP. Is a cap made of leather and covered with black velvet, sitting close to the head behind, and having a semi-circular peak before, for the protection of the face in case of falls as well as in passing through strong covers during the chase. In the old school, he who wore the hunting cap was termed a *Dasher*, under a supposition that the wearer would never swerve from any difficulty, or refuse any leap; but this supposition, however general at one period it might have been, is altogether absurd. Five-and-twenty years ago, hunting caps were in general use; and how they came to be superseded by the hat appears un-

accountable: certain it is, that nothing could be better adapted for the purpose than the cap; while the hat is very inconvenient in a variety of ways, to say nothing of the unsportsmanlike appearance which it gives to the person who wears it. The hat is continually liable to be knocked off by the branches of trees, and when the wind blows it is as troublesome a companion as can well be imagined. Many sportsmen, in order to remedy the inconvenience as far as possible, tie it to the button-hole or some part of their coat with a narrow black ribbon. Surely the hunting cap must shortly be restored.

HUNTING WHIP. The whip so called, is large and heavy, and is intended, of course, for the correction of the hounds. The hunting whip in use some years ago, had frequently a hammer and claw at the butt end of the handle, which, of late, has, in a great degree, been laid aside. At the butt end of the modern hunting whip, there is merely a hook of buck's horn or bone; and some of the younger sort of Meltonians appear in the field with merely the handle or stock of the whip, which, in the eye of a sportsman of even forty years of age, gives them a very inappropriate, and a very unsightly, appearance.

HUNTSMAN. The huntsman is a person whose business it is to superintend every department of a hunting establishment, as well as to hunt the hounds. As it is an office of considerable trust and responsibility, so it requires no inconsiderable share of ability to fulfil it in a proper manner. He should be possessed of a comprehensive mind, a clear head, and humane heart; and of an obliging disposition. He should be remarkable for sobriety, acute perception, personal fortitude, patience, and activity; have a good constitution, an excellent ear, and a sonorous voice.

"It is common enough with our young Squires (observes a writer of the old school) to take the first wide throated attendant who offers his service, and make him his huntsman, imagining the green coat will qualify him for his office; as some set up themselves for doctors with no other recommendation but a pair of large eyebrows, and a set of loud sounding polysyllables.

But as every block will not make a Mercury, much less is he fit for a huntsman who is not born with a natural craft and readiness of mind, and has not im-

proved those talents by long study, observation, and experience.

I once had the pleasure of a long conversation with a very ingenious learned gentleman, then seventy years old; having himself hunted with all sorts of dogs, and in most of the counties in England, he entertained me with a most delightful discourse on that subject; and upon my making him a compliment on his perfect knowledge in the art, 'Oh! Sir (says he) *the life of man is too short!*' This sage declaration was received as a jest by some of the company; but I have since found it a serious truth: I am an old hunter myself; the wiles of the hare have been all along the study of my leisure hours, and yet I am perfectly puzzled and outwitted by that subtle creature. When I think myself sure, she often puts some unexpected trick upon me; and hardly do I ever lose her in tolerable scenting weather, but I can afterwards discern it was the effect of some oversight, or want of provision for such and such a contingency. For the conquest of a hare does not depend only upon vigorous attacks or pursuits, but there are a hundred accidents to which the success of the field is obnoxious, and which ought always to be in the head of the huntsman, if he would come off with glory."

A huntsman (to harriers) must never forget that every hare has her particular play; that, however that play is occasioned or changed, according to the variation of wind and weather, the weight of the air, the nature of the ground, and the degrees of eagerness with which she is pursued. Nor is he to be unmindful of the numerous accidents she may meet with in her way, to turn her out of her course, to cover her flight, to quicken her speed, or to furnish her with an opportunity of new devices. It is not enough to have a general knowledge of these things before the game is started, but in the heat of action, when most tempted to be in raptures, he should calmly observe the alterations of the soil, the position of the wind, the time of the year, and no less notice with what speed she is driven, how far she is likely to keep on forward, or to turn short behind; whether she has not been met by passengers, frightened by curs, intercepted by sheep; whether an approaching storm, a rising wind, a sudden blaze of the sun, the going off of the frost, the repetition of foiled ground, the decay of her own strength, or any other

probable turn of affairs, has not abated or altered the scent.

There are other things which equally claim the huntsman's attention, such as the particular quality and character of each dog; whether the present leaders are not apt to overrun the scent; which are most inclined to stand upon the double; which are to be depended on in the high-way, on greasy fallows, &c. Nor must the hounds be followed so closely, when fresh and vigorous, as after they have run off their speed and mettle.

When the scent lies well, the huntsman should keep considerably behind the hounds. At such a time, especially if it be against the wind, it is impossible for the hare long to hold forward: on such occasions she is very apt to stop short by the way, and when all the hounds have passed, to steal back; and thus the chase is frequently lost: whereas, if the huntsman were not too forward, he might perhaps see her steal back, and be thus enabled to recover what would otherwise have been lost.

The preceding observations relate to the pursuit of the hare, the following are more general, and will of course explain themselves:—Mr. Beckford says, "I will endeavour to describe what a good huntsman should be. He should be young, strong, active, bold and enterprising; fond of the diversion and indefatigable in the pursuit of it: he should be sensible and good tempered: he ought to be sober and exact, civil and cleanly: he should be a good groom and an excellent horseman; his voice should be strong and clear; and he should have an eye so quick as to perceive which of his hounds carries the scent when all are running; and should have so excellent an ear as always to distinguish the foremost hounds when he does not see them. He should be quiet, patient, and without conceit.—Such are the excellencies which constitute a good huntsman. He should not, however, be too fond of displaying them till necessity calls them forth. He should let his hounds alone, while they *can hunt*; and he should have genius to assist them, *when they cannot.*"

Although the qualifications of a huntsman, upon the great scale of universality, should be precisely the same, yet there is an infinite contrast in the various points of execution. No distinct difference of light and shade upon the canvass, no effect of the elements upon the human frame, can be productive of more opposite

sensations than the requisites necessary to form a proper distinction between the modes of hunting hare and fox; since the very means calculated for the promotion of the one, would, in a few minutes, prove the evident destruction of the other: from which it is natural to infer that a huntsman eminently qualified for *either* would never be likely to acquire celebrity for *both*; for, as the accustomed spirit, speed, and dashing impetuosity of the fox hunter would soon lose a hare, so the philosophic patience, and constitutional tardiness, of the hare hunter would never kill a fox.

Perhaps a man who has reached the meridian of life, or one who has even passed it, would be, generally speaking, better calculated for a huntsman to harriers than a person in the full vigour of youth: at all events, he should be quiet and patient; "for patience he should be a very grizzle; and the more quiet he is, the better." A huntsman to a pack of harriers should have infinite perseverance; as a hare should never be given up while it is possible to hunt her:—she is sure to stop, and therefore may always be recovered.

It is generally supposed that the scent of the fox is more powerful than that of the hare, and this in all probability is the case; but the general supposition does not stop here; on the contrary, the prevalent notion among sportsmen is, that the scent of the fox is also more volatile, or evaporates sooner, than the scent of the hare. But the truth of this position we very much doubt (see the article SCENT). Fox-hounds are fleet sharp-nosed dogs (or at least they are generally so) and go with great speed while they can keep near the fox; but their noses are by no means so good as the generality of harriers; and on this account they are seldom able to hunt if the fox passes even but a short period before them—hence in all probability has arisen the notion of which we have been speaking. Harriers will hunt a fox more eagerly than they will a hare; and the writer has little doubt, that as the scent of the fox is more powerful or stronger, so also will it remain as long as that of the hare: consequently the seeming difference arises, not so much from the unequal volatility of the scent of the hare and the fox, as from the difference of the olfactory organs of the dogs by which the animals are pursued. We have already remarked, that harriers will hunt a fox more eagerly than they will follow a hare, which arises, no doubt, from the circumstance of the

effluvium which constitutes scent, being more powerful, and more easily carried on, than that of their own chase; nor have we the least doubt that harriers will acknowledge, or challenge, the scent of a fox as long as they will that of a hare, if not longer. The reason why harriers are not able to kill a fox in good style arises from their want of power and speed: they are neither so large nor so strong as fox-hounds; and if hounds by which a fox is pursued are not able to hunt well up to him, the chase must necessarily be protracted, and the fox will generally escape.—Generally speaking, when foxes are killed by harriers they are merely hunted down; while fox-hounds run up to their game, and kill him in style.

In regard to the pursuit of the different objects of the chase, sportsmen assert that "the scent of the stag, the fox, and the hare, is so exceedingly different in the duration of each, that it requires a method proportionably different in the pursuit of either; all which is practically known to huntsmen, who have no alternative, but to render their endeavours applicable to the kind of chase they are destined to pursue. The scent of the fox is well known to be the most powerful, as well as the most volatile, of any; the scent of the stag is equally grateful to hounds, but is known to evaporate sooner than the scent of the hare." The remarks we have already made are equally applicable here, namely, that the difference arises rather from the noses of the dogs than the quality of the scent, though we have reason to believe the scent of the fox (as already observed) is not only more powerful, but more lasting also; the scent of the stag we regard as the next both in strength and durability; and as to the hare, the scent which she leaves is, in our opinion, neither so powerful, nor yet so lasting.

But each of these animals requires a different style in the pursuit. In the two first, clamorous exultation upon view is more customary and more in character, than in the latter. Stag or fox break away in an undaunted manner; seek safety in persevering speed; and consequently the hounds cannot be laid on or kept too close to them, to fox in particular. But the case is different in hare hunting; where a general silence should prevail; and where the endeavours of the pack should never be obstructed by the busy tongues of officious obtruders; and upon this well-founded position, that if they receive no assistance, they encounter no opposition.

Harriers, as well as their huntsmen, are by no means calculated for the pursuit of the fox.

When a hare is found, she cannot be permitted to go off too silently; her own extreme timidity frequently occasions her heading, and the pack are as repeatedly liable to overrun the scent. The huntsman, by not pressing too close upon the hounds himself, may perhaps influence the company to keep at a proper distance also; and when the hounds are left to a proper and free use of their faculties, they are by no means so likely to overrun the scent.

In the pursuit of the hare, Beckford says, that "hounds, through the whole chase, should be left almost entirely to themselves, and not be much hallooed: when the hare doubles, they should hunt through those doubles; nor is a hare hunted fairly, when hunted otherwise. They should follow her every step she takes, as well over greasy fallows, as through flocks of sheep; nor should they ever be cast, but when nothing can be done without it."

The case is very different in the pursuit of the fox; where the huntsman should go off with the leading hounds, and press them forward as much as possible while they are able to carry the scent. The moment the hounds come to a check, they should be suffered to make their own cast, and perhaps as long as they will try to recover the scent themselves, the huntsman had better not interfere; but the moment they come to a stand, is the moment for the huntsman to display his abilities, and that too without the least loss of time.

When a huntsman makes a cast, he should make it perfect one way before he tries another, as much time is lost by going backwards and forwards; and the huntsman should be quick in his motions. Some huntsmen, when a forward cast does not succeed, come slowly back again; they should return as fast as they can.

When hounds are at fault, and it is probable that the fox has headed back, the cast forward should be short and quick; the scent is then likely to be behind, and too obstinate a perseverance forward has been the loss of many foxes.

There are times when hounds should be helped, and at all times they must be kept forward: hounds will naturally tie on a cold scent, when stopped by sheep or other impediments; and when they are no longer able to get forward, will

oftentimes hunt the old scent back again, if they find that they can hunt no other. It is the judicious encouraging of hounds to hunt when they cannot run, and the preventing them from losing time by hunting too much when they might run, that distinguishes a good huntsman from a bad one. Hounds that have been well taught will cast forward to a hedge of their own accord; but this excellence can never be acquired but from proper instruction. To suffer a pack of fox-hounds to hunt through a flock of sheep when it is so easy to make a cast round them, is the height of absurdity—it is losing time to no purpose.

In chases and forests, where high fences are made to preserve the coppices, the huntsman should put only a few hounds over, enough to carry on the scent, and get forward with the rest—it is a proof that he knows his business.

A huntsman should take care where foxes are in plenty that he does not run the heel; as it frequently happens that hounds can run the wrong way of the scent better than they can the right, when one is up the wind and the other down.

Huntsmen uniformly try down the wind, before they try up—some indeed will not try up at all; and no doubt frequently lose the fox by their ill-timed obstinacy.

When a huntsman hears a halloo, and has five or six couple of hounds along with him, the pack not running, let him get forward with those which he has; when they are on the scent, the others will soon join them.

Sometimes a good kennel huntsman is met with; sometimes an active and judicious one in the field; some are clever at finding a fox; others are better after he is found; whilst perfection in a huntsman, like perfection in any thing else, is scarcely ever seen. The keeping hounds clean and healthy, and bringing them into the field in their fullest vigour, is the excellence of a good kennel huntsman: if, besides this, he makes his hounds both love and fear him; if he is active and presses them on while the scent is good, always aiming to keep as near the fox as he can; if, when his hounds are at fault, he makes his cast with judgment; if, added to this, he is patient and persevering, never giving up a fox whilst there is a chance of killing him; such a person may be regarded as an excellent huntsman.

"I have always thought a huntsman a

happy man (says Beckford); his office is pleasing, and at the same time flattering; we pay him for that which diverts him, and he is enriched by his greatest pleasure; nor is a general after a victory more proud, than a huntsman who returns with a fox's head.

"I have heard that a certain Duke, who allowed no vails to his servants, asked his huntsman what he generally made of his field money, and gave him what he stated instead of it. This went on very well for some time, till at last the huntsman requested an audience:—"Your Grace (said he) is very generous, and gives me more than ever I got from field money in my life; yet I come to beg a favour of your Grace—that you would let me take field money again; for I have not half the pleasure now in killing a fox that I had before."

Huntsmen, whilst their hounds are drawing, or are at fault, frequently make so much noise themselves that they can hear nothing else: they should always have an ear to a halloo. "I once (says Beckford) saw an extraordinary instance of it in my own huntsman, who was making so much noise with his hounds, which were then at fault, that a man hallooed a long time before he heard him: and when he did hear him, so little did he know whence the halloo came, that he rode a couple of miles the wrong way, and lost the fox."

A huntsman to a pack of fox-hounds, went out one morning so very drunk that he got off his horse in the midst of a thick cover, laid himself down and went to sleep:—he was lost: nobody knew what was become of him, and he was at last found in the situation just described. He had, however, great good luck on his side; for, at the very instant he was found, a fox was hallooed; upon which he mounted his horse, rode desperately, killed his fox handsomely, and was forgiven.

The following is related of a sulky huntsman:—Things did not go on to please him; he therefore alighted from his horse in the middle of a wood, and, as quietly as he could, collected his hounds about him: he then took an opportunity, when the coast was clear, to set off silently and by himself for another cover; however, his master, who knew his tricks, sent others after him to bring him back: they found him running a fox most merrily, and to his great astonishment they stopped the hounds and made him to go back along with them. This fellow had

been often very severely beaten, but was stubborn and sulky to the last.

It is not necessary to enter more at large on the qualifications or duties of a huntsman; as, in that case, we should be compelled to repeat what has already appeared under the articles *FOX HUNTING* and *HARE HUNTING*, to which we therefore refer the reader. We shall here introduce a slight notice of a huntsman, whose eccentricities and other qualities seem to merit particular notice.

Isaac Rogers, though better known in the West of England by the name of the Doctor, was born at Montecute in Somersetshire. When a lad, he was instructed in shoe making; but early evincing a fondness for horses and hounds, Mr. Philips, the grandfather of the present owner of Montecute House, took him from the cobbler's stall, and placed him as understrapper in the stables—a state much more congenial to the Doctor's taste; and he remained in the service of the family the remainder of his life—about sixty-two years.

At one period he was groom, after that postilion, and then he became whipper-in; and on the death of a then old huntsman, Amos, he was promoted to the rank of huntsman. One of his sons, named Jack, and who was a very good sportsman and rider, was appointed whipper-in and the other feeder.

The Doctor, when drawing Prince's Wood, one day, on some of the hounds challenging, was asked why he did not cheer them? "Because (said the Doctor) we have a good many young hounds out, and I am afraid it be nothing *but some small varment*." The Doctor, for some minutes more, sat in anxious expectation of hearing some of his old friends, when presently two or three of them began to give tongue; on which the Doctor began to open his pipes and exclaimed, "Hark to ould Bowler, Vengeance, and Warhoop! *Now the right bell have a tolled!*"

The hounds having in a fog, and on a very high scenting day, ran away from the whole field, it was not until an hour after that the Doctor got up to them, when he found them returning by themselves; on which the Doctor observed, that he verily believed they had killed their fox. Mr. Philips, who was present, said, "Doctor, you had better get off and smell their breath; you will soon find if they have killed their fox or not." The Doctor, imagining at the moment that his master was not in earnest, but meant it

as a joke, turned short round, and, with one of his arch looks, replied—"No, no, measter; that will never do—a pretty story would be carried up along into the New Forest next April, that the Doctor did not know when his hounds had killed their fox, without geeting of to smell to the breaths o'em."

One of the gentlemen of Mr. Philips's hunt overtook the Doctor with his pack one morning, on his road to Melbury, where they were to throw off, and remarking that the long chase the day before had rather tired him, the Doctor, in his blunt manner, quaintly replied, "If you be tired with a two hours' ding yesterday, what must I be then, for this be the zeven-and-vortieth day vollying that I've hallied to a hound, save and except Sundays."

A gentleman who kept a noble pack of fox-hounds being once on a visit to his friend Mr. Philips of Montecute, on his leaving that place, he invited the Doctor to go and see his hounds, and taste the strong beer. As soon as hay-making was over, at which the Doctor played a very pretty pitchfork, he started to pay his promised visit, and on being shewn the hounds, the gentleman said, "Well, Doctor, how do yo like my hounds?"—"Why (said the Doctor) they be pictures to look at, *but they bayn't half so scratched in the face as our ould measter's be down at Montecute.*"

Some gentlemen meeting the Doctor with the pack one morning going to cover, asked him where they were going? "*Why (says the Doctor) we be going to try if we can't tackle thick Whitfield fox that have a beat us vour times. I've drafted vour-teen couple of sich rogues, that if he don't look pretty sharp, I count in about three quarters of an hour they will be for sucking his blood.*"

So thoroughly attentive was he, that if he ran a fox to ground, and suspected a gin might be set at night, or a fox dug, after taking care of his hounds, he would set off on a pony, although the distance might be ten or twelve miles, to ascertain if all was right.

The Doctor was all animation from the moment old Bowler, Warhoop, Warrior, Tidings, or Vengeance, or some other of his old favourites, had pushed him out of his kennel: his mind, from that instant, was never at rest until he had properly accounted for him. One day, after running a fox hard, and they had got him into a small coppice, where the hounds were scoring at him, and he, to escape them, began running short, and every moment skipping behind them—the Doctor, addressing himself to a Mr. B. said, "*Mr. B. its pretty well up with him—don't ye hear how angry ould Shark, the bandy legged tarrier, be with him?*"

*Epitaph on Isaac Rogers, huntsman to the Rev. Wm. Philips, of Montecute, Somerset.*

Now the Doctor is laid, and over his head  
May the turf lie as light as a feather!  
And if not very warm, it will do him no harm,  
Who ne'er valued the wind, nor the weather.

He's no longer in view; but to give him his due,  
Though not born nor bred for a college,  
Death ne'er drove to the earth a man of more worth,  
More science or practical knowledge.

Isaac Rogers his name; a huntsman, whose fame  
From the Yeo to the Avon resounded:  
At his musical voice, Clift Wood would rejoice,  
Dev'rill Longwood its echo rebounded.

As in life's busy burst, he was never the first  
To hit off a fault in a neighbour,  
Now he's fairly stopt in, let us hope that he'll win  
The brush of reward for his labour.

*Seventy-four years of age.*

Good temper is a most desirable quality in a huntsman, as circumstances frequently occur where it is put to a very severe trial:—when, for instance, a fox is

found, imprudent sportsmen are apt to ride over the scent, as well as to head him back. If the cover be small, so that the fox cannot go away unseen, heading back may not perhaps be of very great consequence; but the case is frequently very different, and very vexatious; but to ride over the scent is, I think, more provoking. When a fox has just broke cover, and before the hounds have got settled to the scent, how often have I seen the scent ridden over! and that too in the most vexatious manner: it certainly is not to be wondered at, however it may be regretted, if, on such occasions, the huntsman should forget the respect due to his superiors. On the 7th of last January (1826) I met the hounds of Hugo Meynell, Esq. at Radborne, about three miles from the town of Derby. A fox was found in a cover called *the Pasture*: he was well viewed away; in fact, he went off in such a manner as to enable a number of thoughtless and highly reprehensible sportsmen to ride before the hounds—they rode over the scent: the hounds endeavoured to pick it out from among the horse's legs; but the the country presenting no *formidable fences*, the mercurial spirits above alluded to were enabled to head the hounds repeatedly, so that they could not get settled to the scent; and we ultimately lost the fox! Could any thing be more provoking? A few weeks prior to this period, I met the York and Ainsty fox-hounds at Skelton Springs, near York. We found in Overton Wood, a cover of very considerable extent; which renard seemed very unwilling to leave. At length, he broke away, and faced the open country in the direction of Benningborough; but, at a short distance from the wood, he crossed a lane, where several secondary sportsmen were waiting; who rode over the scent in all directions: and though the pursuit was continued for more than half an hour, the hounds were unable to run well up to their fox, (owing, no doubt, to the circumstance just mentioned) and we of course lost him. However, Naylor, the huntsman, kept his temper; though he informed me, that, some time before this period, he had broken out into a great rage, in consequence of a gentleman, not merely riding over the scent, but also over the best hound in the pack, and killing it!

I have met with several huntsmen who possessed good sense, who were not altogether destitute of what is understood by

the word genius; but who, however, had received scarcely a common village education. The famous Dick Knight, who was huntsman to Lord Althorp, and who, with his favourite horse (Contract) is represented in a well-known series of engravings, was as illiterate as possible, but occasionally elicited something like strokes of genius. This man was a great favourite with his master; was a desperate rider; and one who excelled in low games at cards, in which he passed most of his leisure hours. The features of Dick Knight's face were by no means prepossessing; yet they were strongly marked, and very expressive. He is celebrated for several extraordinary feats, amongst which, his leap down the precipice, known by the name of Dick Knight's leap, was, perhaps, the most dangerous. Dick had repeatedly run a particular fox, which uniformly beat his hounds; this same fox became well known, and Knight always knew where to find him. Renard invariably made for and reached a cover, (Cank Wood) distant about ten miles, in defiance of every exertion made to kill him; and in this cover he uniformly eluded all further pursuit. Knight was bent on killing this fox, whose acknowledged game ought, however, to have insured him fair play; but Dick, chafed by the sneers of the sportsmen who attended his hounds, and finding it impossible to kill this fox in the ordinary manner, adopted the following mode in order to accomplish his purpose. He gave his whippers-in the requisite directions as to the manner in which they were to second his exertions; and, placing himself in a situation where he might be able to view away his old acquaintance, the hounds were thrown into cover, the fox found, and viewed off by Dick Knight. But Knight was not content with this; he had resolved to keep him company as long or as far as possible; he therefore went away with him, and kept him in sight for four or five miles; this was an exertion of which very few would have been capable; but it answered the purpose, (not a praiseworthy purpose certainly;) for, by this method the fox was so pressed and so blown, that he was unable to reach the place that had always afforded him secure protection: however, he made the most desperate efforts, and the hounds reached him only one mile from his place of safety!

Shaw, one of the most famous huntsmen of modern days, appeared to have

## H U N

something like genius in his composition, though he was not able to write till he entered the service of the Duke of Rutland, when he was about thirty years of age. The first time I ever saw this man was with the the harriers of Lord Moira (Marquis of Hastings) about thirty-five years ago, to which he was huntsman, and it was the first season he had ever acted in that capacity. These harriers were afterwards replaced by fox-hounds, and Shaw continued to hunt them (several years) till they were sold by Lord Moira to Sir Henry Harper, of Caulk, Derbyshire. Shaw afterwards became huntsman to Sir Thomas Mostyn; and ultimately served the Duke of Rutland in that capacity; with both of whom he was a great favourite. He continued in the Duke's service for a series of years, until, in fact, he was afflicted with some disorder, which disabled him from fulfilling the duties of his office. He quitted the service of his Grace for some time, and returned again at the express desire of the latter; but he was still incapable of going through the fatigue necessarily attendant upon the office of huntsman, and he retired. Such, however, had been the kindness of his master, that Shaw had realized, not a splendid fortune, but sufficient to live respectably, and keep a couple of hunters. When Sir Bellingham Graham had the Pycheley hunt, Shaw was frequently out; he also visited other parts, and I believe resides at present in Northamptonshire.

Shaw was not only a favourite with the Duke, his master, but with those who attended his hounds. He was a good horseman, very active in the field, civil and respectful, and sometimes manifested what Beckford would call genius. Shaw

## H U R

became a huntsman without proceeding through those probationary steps, which generally lead to the office:—he never officiated in the subordinate capacity of whipper-in.

I have seen several good huntsmen within the last score years; and I am of opinion that few packs of fox hounds were ever better managed in the field than the Quorndon, a few years ago, when Sebright was the huntsman, assisted by those two very active whippers-in, Richard Burton and Will Head.

Richards, who hunts the Badsworth, seems to understand his business; but, unfortunately for a huntsman, he cannot be called a *light weight*. He is, however, a good rider, and an active man in the field. In the year 1825, I visited the Badsworth; and had thus an opportunity of observing the motions of Richards: I proceeded to Lord Harewood's hunt, where the operations of George Payne (his Lordship's huntsman) formed a striking contrast to those of Richards. The hounds must, in a certain degree, take their tone and manner from the huntsman:—the Badsworth are quick and active; Lord Harewood's are more slow and more *philosophical*. There was one hound in particular, in Lord Harewood's pack, that struck my attention: I remarked to Payne, the huntsman, that I was much pleased with the hound in question:—"That hound, Sir, (said he) would hunt through York Minster."

**HURLE OR WHIRLE BONE** is situate in the central part of the hind-quarter, midway between the hip-bone and the gaskin, and is at present called the *round-bone*.

**HYDROPHOBIA.** See **DISEASES OF DOGS.**

## I & J

**JANUARY.** The pursuit of the partridge and pheasant ceases at the end of this month; though wood-cocks, snipes, and wild-fowl still remain an object with the shooter.

The hare will afford good diversion either with greyhounds or harriers, as hares are very strong at this period of the year.—The buck and doe seek the company of each other, if the season be mild and open.

Foxes run very stoutly, and good sport with the hounds may be confidently anticipated, unless prevented by the severity

of the weather. The dog fox and vixen seek each other.

**JARDON.** A jardon was the name given to any callous enlargement on the outside of either hock, proceeding from blows, or by kicks from other horses; although they more frequently arise from sudden turns or twists in too short a compass, or being too violently thrown upon their haunches in the manege, or elsewhere. In slight affections, they are not always productive of pain or lameness; and if properly attended to upon their first appearance, are sometimes re-

duced and obliterated without any future ill effect. Powerful repellents, and strengthening embrocations, are the most efficacious applications. Blistering first, and firing afterwards, have been the usual practice. It is, however, certain they are, in general, too hastily adopted. Daily fomentations of hot vinegar, followed by a strong embrocation of extract of Saturn, and camphorated spirits, might probably prevent the necessity for either.

**JAUNDICE.** A disease in the horse, termed by farriers the *yellow*s. Horses are frequently subject to this malady, but in them it is less liable to be complicated with other diseases than in men, and therefore, when early discovered, may, for the most part, be easily removed.

The signs of the jaundice in horses, are a dusky yellowness of the eyes; the inside of the mouth and lips, the tongue and bars of the roof of the mouth, look also yellow. But here we are to distinguish between the yellowness of the jaundice, and that yellowness of the mouth and eyes which sometimes happens to horses upon the crisis of an inflammatory fever, where the inflamed parts look yellow when the fever and inflammation are going off. When this happens after a fever, the horse generally comes to his appetite, and looks lively, and the fever leaves him, the yellowness also soon wears off. But, in the jaundice, the yellowness is one of the first symptoms, and generally appears in the beginning of the complaint. The horse is dull, and refuses all manner of food, and the fever begins slowly, yet both that and the yellowness soon increase and proceed together. In the decline of an inflammatory fever, a horse dungs and stales freely, and in a kindly manner. In the jaundice, his dung is often hard, dry, and of a pale yellow, or light pale green. The urine is commonly of a dark dirty brown colour, and, when it has settled sometime on the pavement, it looks red like blood. He also stales with some pain and difficulty; and, if the disease be not soon checked, all the symptoms will increase, and the horse soon grows delirious. In cases of jaundice the assistance of a skilful veterinarian should be called in.

**IMPOSTHUME.** An imposthume is that kind of inflammatory enlargement, or swelling, which terminates in the formation of matter, produced by an effort of nature to relieve herself from some offending morbidity under which she labours.

**INCUBATION.** A hen has scarcely sat on the egg twelve hours, when some lineaments of the head and body of the chicken appear. The heart may be seen to beat at the end of the second day; it has at that time somewhat of the form of a horse shoe, but no blood yet appears. At the end of two days the vesicles of blood are to be distinguished, the pulsation of which is very visible: one of them is the left ventricle, and the other the root of the great artery. At the end of the fiftieth hour, one auricle of the heart appears, and resembles a nose, folded down upon itself. The beating of the heart is first observed in the auricle and afterwards in the ventricle. At the end of seventy hours the wings are distinguishable; and on the head two bubbles are seen for the brain; one for the bill; and two others for the fore and hind part of the head. Towards the end of the fourth day, the two auricles, already visible, draw nearer to the heart than they did before. The liver appears towards the fifth day. At the expiration of one hundred and thirty-four hours, the first voluntary motion is observed; in seven hours more, the lungs and stomach become visible; and four hours after this, the intestines, the loins, and the upper jaw. At the hundred and forty-fourth hour, two ventricles are discerned, and two drops of blood, instead of the single one which was seen before. The seventh day, the brain begins to have some consistence. At the hundred and ninetieth hour of incubation, the bill opens, and the flesh appears in the breast; in four hours more, the breast bone is seen; and in six after this, the ribs appear, forming from the back; and the bill is plainly seen as well as the gall bladder. The bill becomes green at the end of two hundred and thirty-six hours; and if the chicken is taken out of its coverings, it evidently moves itself. The feathers begin to shoot out towards the two hundred and fortieth hour, and the skull becomes gristly. At the two hundred and sixty-fourth, the eyes appear. At the two hundred and eighty-eighth, the ribs are perfect. At the three hundred and thirty-first, the spleen draws near the stomach, and the lungs to the chest. At the end of three hundred and fifty-five hours, the bill frequently opens and shuts; and at the end of the eighteenth day, the first cry of the chicken is heard. It afterwards gets more strength and grows constantly, till at length it is enabled to set itself free from its confinement.

In the total of this process must be remarked, that every part appears at the appropriate time: if, for example, the liver is formed on the fifth day, it is founded on the preceding situation of the chicken, and on the changes which are to follow. No part of the body could possibly appear, either sooner or later, without the whole embryo suffering; and each of the limbs becomes visible at the proper moment. This ordination, so invariable in its effects, is manifestly the work of a supreme Being, whose creative powers must be still more sensibly acknowledged, when the manner in which the chicken is formed out of the parts which compose the egg is also considered: how astonishing it is that in this there should exist the principle of life: that all the parts of an animal's body should therein be concealed, and require nothing but heat to unfold and quicken them—that the formation of the bird should be so regular—that exactly at the same instant the same changes will take place in a great number of eggs—that the chicken, when hatched, is heavier than the egg was before. But even these are not all the wonders in the production of the bird from the egg (and this instance will serve to illustrate the whole feathered race); there are others, which, from our limited faculties, are altogether hidden from our research.

Hatching chickens by artificial heat, is a process that has been long known in Egypt: (it was successfully tried by Mr. Potter, in the isle of Ely, both with hens' and pheasants' eggs); but this is only now practised by the inhabitants of a single village called Berme, and by those who live in its immediate vicinity. About the beginning of autumn, these persons spread themselves all over the country, and each of them is ready to undertake the management of an oven. These ovens are of different sizes, capable of containing from forty to eighty thousand eggs; and the number of ovens, in different parts, was about three hundred and eighty. These were annually kept working for about six months; and as each brood takes up twenty one days in hatching, it is easy in every one of them to produce eight different broods of chickens in the year.

The ovens are of the most simple construction, consisting of only a low arched apartment of clay. Two rows of shelves are formed, and the eggs are placed so as not to touch each other.

They are slightly moved five or six times in every twenty-four hours. All possible care is to be taken to diffuse the heat equally throughout; and there is but one small aperture large enough to admit a man stooping. During the first eight days, the heat is rendered great; in the last eight, it is gradually diminished, till at length, when the young brood is ready to come forth, it is reduced almost to the state of the natural atmosphere. At the end of the first eight days, it is known which of the eggs will not be productive.

Every person who undertakes the care of an oven is under the obligation of delivering to his employer only two thirds of as many chickens as there have been eggs given to him; and he is a gainer by this bargain, as it always happens (except from some unexpected accident) that more than two thirds of the eggs produce birds. In order to make a calculation of the number of chickens thus hatched yearly in Egypt, it has been supposed that, upon an average of only two-thirds of the eggs being productive, and that each brood consists of at least thirty thousand chickens, the ovens, by this estimate, give life, annually, to about 92,600,000 of these animals.

M. de Reaumur introduced this advantageous mode of hatching eggs into France, and by a number of ingenious experiments, reduced the art to certain principles. He found that the degree of heat necessary for the production of all kinds of domestic fowls was the same, the only difference consisting in the time during which it ought to be communicated to the eggs: it will bring the canary bird to perfection in eleven or twelve days, while the turkey poult requires from twenty-four to twenty-eight. M. de Reaumur found that stoves heated by means of pipes from a baker's oven, or the furnace of glass houses, succeeded better than those made hot by layers of dung, the mode preferred in Egypt.—These should have their heat kept as nearly equal as possible, and the eggs should be frequently removed from the sides into the middle, in order that each may receive an equal portion of heat. After the eggs were hatched he had the offspring put into a kind of low boxes without bottoms, and lined with fur, the warmth of which supplied that of the hen, and in which the chickens could at any time take shelter. Till the chickens acquired some strength, these boxes were kept in a warm room; with safety they then could be exposed to

the open air in a court yard. The young seldom take any food the whole day after being hatched ; then a few crumbs of bread are given for a day or two, after which time they begin to pick up insects and grain for themselves. That the trouble of attending them might be saved, M. de Reaumur taught capons to watch them in the same manner as hens, of which three or four were sufficient to take care of two hundred chickens.

From the incubation of eggs, Dr. Paley makes some highly interesting observations respecting animal instinct. He thus proceeds :—" I entertain no doubt but that a couple of sparrows hatched in an oven, and kept separate from the rest of their species, would proceed as other sparrows do in every office which related to the production and preservation of their brood." Assuming this fact, the thing is inexplicable upon any other hypothesis than that of an instinct impressed upon the constitution of the animal. For, in the first place, what should induce the female bird to prepare a nest before she lays her eggs? It is in vain to suppose her to be possessed of a faculty of reasoning ; as no reasoning will reach the case. The fulness or distention which she might feel in a particular part of her body, from the growth and solidity of the egg within her, could not possibly inform her that she was about to produce something, which, when produced, was to be taken care of and preserved. Prior to experience there was nothing to lead to this inference or to this suspicion. The analogy was all against it ; for in every other instance, what issued from the body was cast out and rejected. But, secondly, let us suppose the egg to be produced into day—how should birds know that their eggs contain their young? There is nothing either in the aspect, or in the internal composition of an egg, which could lead even the most daring imagination to a conjecture, that it was hereafter to turn out from under its shell, a living perfect bird. The form of the egg bears not the rudiments of a resemblance to that of the bird. Inspecting its contents, we find still less reason, if possible, to look for the result which actually takes place. If we should go so far as, from the appearance of order and distinction in the disposition of the liquid substances which we noticed in the egg, to guess that it might be designed for the abode and nutriment of an animal (which would be a very bold hypothesis) we should expect a tadpole dab-

bling in the slime, much rather than a dry, winged, feathered creature ; a compound of parts and properties impossible to be used in a state of confinement in the egg, and bearing no conceivable relation, either in quality or material, to any thing observed in it. From the white of an egg, would any one look for the feathers of a goldfinch? or expect from a simple uniform mucilage the most complicated of all machines, the most diversified of all collections of substances? Nor would the process of incubation, for some time at least, lead us to suspect the event. Who that saw red streaks shooting in the fine membrane which divides the white from the yolk, could suppose that these were about to become bones and limbs? Who, that espied two discoloured points first making their appearance in the cicatrix, would have had the courage to predict that these points were to grow into the head and heart of a bird? It is difficult to resuscitate surprise when familiarity has once laid the sentiment asleep. But, could we forget all that we know, and which our sparrows never knew, about oviparous generation ; could we divest ourselves of every information but what we derived from reasoning upon the appearances or qualities discovered in the object presented to us, there is every reason to believe that harlequin coming out of an egg upon the stage is not more astonishing to a child, than the hatching of a chicken both would be, and ought to be, to a philosopher. But admit the sparrow, by some means, to know, that within that egg was concealed the principle of a future bird, from what chemist was she to learn, that warmth was necessary to bring it to maturity ; or, that the degree of warmth imparted by the temperature of her own body, was the degree required?—To suppose, therefore, that the female bird acts in this process from a sagacity and reason of her own, is to suppose her to arrive at conclusions which there are no premises to justify. If our sparrow, sitting upon her eggs, expect young sparrows to come out of them, she forms a wild and extravagant expectation, in opposition to present appearances and to probability. She must have penetrated into the order of nature further than any faculties of our's will carry us ; and it has been well observed that the deep sagacity, if it be sagacity, subsists in conjunction with great stupidity, even in relation to the same subject. " A chemical operation (says Addison) could not be followed by

greater art and diligence than are seen in hatching a chicken ; yet is the process carried on without the least glimmering of thought or common sense. The hen will mistake a piece of chalk for an egg ; is insensible of the increase or diminution of their number ; does not distinguish between her own and those of another species ; is frightened when her supposititious brood of ducklings take the water."

But it will be said that what reason could not do for the bird, observation, or instruction, or tradition, might. Now, if it be true that a couple of sparrows, brought up from the first in a state of separation from all other birds, would build their nest, and brood upon their eggs, then there is an end of this solution. "But what (continues Dr. Paley) can be the traditionary knowledge of a chicken hatched in an oven?"

**INJECTIONS.** Many medical solutions and lotions are so called ; though the word more properly applies only to such compositions as are prepared solely for the purpose of being conveyed into such remote cavities, or sinuses, as may be formed by accident, imposthume, or disease, in any part of the body.

**INTERFERE.** A horse was formerly said to interfere, when one fetlock-joint received an injury in action, by a cut or blow from the foot of the other leg.

#### JOCKEY CLUB, RULES AND ORDERS OF THE.

*New Rooms, Newmarket,  
29th Oct. 1828.*

At a general meeting of the members of the jockey club, the following rules and orders were unanimously approved of and agreed to be adopted as rules and orders of the jockey club, to commence and be in force from the 1st of January, 1829.

1. That the former published rules and orders of the jockey club be repealed on the 31st of December, 1828, and the following rules and orders be thence substituted and acted upon.

2. *Respecting the Stewards.* The three members of the jockey club, now acting as stewards, shall be continued in their office till the next annual meeting of the jockey club, when the senior steward (the one who has been the longest in office) shall quit his station immediately after the settling of the accounts at that meeting, and shall then name a member of the jockey club to succeed him, subject to the approbation of the remaining stewards and of the members of the jockey club then

present ; and at every subsequent annual meeting, the then senior steward shall in like manner retire and name his successor.

3. If any difference of opinion should arise on such nomination, it shall be decided by a majority of the members present ; which majority must include one (at least) of the continuing stewards ; if both the continuing stewards are in the minority, then there shall be a fresh nomination.

4. If any of the stewards should die or resign between the periods of the annual meetings, the surviving or continuing stewards may appoint a member of the club to succeed the deceased or declining steward, and to stand in his place in point of seniority ; but such nomination shall be notified to the club at their next annual, or at any special, meeting to be called for that purpose, and shall then be subject to the like approbation, as in the case of a senior steward retiring at the expiration of his stewardship.

5. All disputes relating to racing at Newmarket, or bets on racing elsewhere, if any of the parties interested should request the interference of the stewards, shall be determined by the three stewards and two referees (who shall be members of the club) one to be chosen by each of the parties concerned, if either of them shall desire to have referees. If only two stewards be present, they shall fix upon a third person, being a member of the club, in lieu of the absent steward ; but the stewards, if they think fit, may call in any other members of the jockey club to their assistance ; or may refer the case to a general meeting of the jockey club, if the importance or difficulty of the matter in dispute shall appear to them to require it.

6. If any dispute, arising elsewhere than at Newmarket, shall be referred to the stewards of the jockey club, and they shall think fit to take it into consideration, the matter must relate to horse-racing, the facts be reduced to writing, and be sent by, or with the sanction of, the stewards of the races where the matter in question occurred. All communications of this kind must be addressed "To the keeper of the match-book at Newmarket," and delivered free of postage.

7. The three stewards, or any two of them, shall have full power to make such regulations as they may think proper in regard to the course and exercise ground.

8. The three stewards shall have the power of appointing such person or per-

sons as they choose, to keep the coffee-room, the match-book, receive the stakes, and collect the entrance-money, and all other funds belonging to the jockey club; and the stewards shall be responsible to the jockey club for all the money collected as belonging to the club. They shall also have the power to appoint the judge of the races, clerk of the course, and other servants of the club.

9. The stewards shall fix the hour of starting for each race, by nine o'clock in the evening preceding the day of running, and notice of the time of starting is to be fixed up in the coffee-room immediately afterwards.

10. The stewards shall produce an account of the funds and disbursements of the jockey club at the annual meeting in each year.

11. *Respecting the admission of new members for the jockey club.* The ballot for members of the jockey club shall be in the New Rooms at Newmarket, or in such other place as the stewards shall appoint, on the Tuesday in the first spring meeting, and the Tuesday in the second October meeting of each year. Each candidate must be proposed by a member, and his christian and surname and usual place of abode, with the name of the member proposing him, put up in the dining and card rooms, at Newmarket (or in such other place as the stewards shall appoint), in the meeting preceding the ballot. Nine members (at the least) shall ballot; and two black balls shall exclude.

12. *For the New Rooms.* The ballot for members of the New Rooms may be in any of the seven established meetings at Newmarket. Each candidate must be proposed by a member of the jockey club, and his christian and surname and usual place of abode, with the name of the member proposing him, put up in the dining and card-rooms at Newmarket (or in such other place as the stewards shall appoint) on the day preceding the ballot. The ballot shall be in the morning between the hours of eleven and one, or in the afternoon between the hours of four and six. Members of the jockey club only shall be allowed to ballot. Nine members (at least) shall ballot, and two black balls shall exclude. If eighteen members ballot, there must be three black balls to exclude.

13. A member of any of the clubs in St. James's Street, known by the name of White's, Brookes's, and Boodle's, may

be admitted a member of the New Rooms without ballot, on paying the same sum for his admission, and the same subscription, as are required of members chosen by ballot.

14. *For the Coffee Room.* The ballot for members of the coffee-room shall take place in the coffee-room at Newmarket (or at such other place as the stewards shall appoint) on any day in the present seven established meetings, between the hours of eleven and one o'clock in the morning. Each candidate must be proposed by a member of the jockey club, and his christian and surname, and usual place of abode, with the name of the member proposing him, be put up in the coffee-room the day before the ballot. Members of the jockey club only can ballot. Twelve members (at least) must ballot, and two black balls shall exclude.

15. Any member of the new rooms may become a member of the coffee-room, on signifying his wish to be so to any of the stewards, or to the keeper of the coffee-room, and paying for his admission and subscription, as members chosen by ballot are required to do.

16. A person, though chosen, shall not be considered as a member of any of these clubs until he shall have paid the usual sums for the admission and subscription of a new member. And the name of every member, whose subscription shall be in arrear for one year, shall be placed over the chimney-piece in the new rooms and in the coffee-room at Newmarket, in the Craven meeting of each year. And if such arrear be not paid by the end of the following second spring meeting, he shall cease to be a member, and shall not be again admitted as a member until his arrears be paid, and until he be again chosen by ballot.

17. *As to Nominations.* In all nominations and entrauces for stakes, subscriptions, and plates, of horses, &c. which have not started previously to the time of naming or entering, the sire, dam, and grandam of the horse, &c. named or entered, must be mentioned, if known, unless the dam has a name which is to be found in the Stud-Book or Racing Calendar, in which case the name of the sire and dam will be sufficient. If the horse, &c. named or entered be own brother or sister to any horse, &c. having a name in the Stud-Book or Racing Calendar, it will be sufficient to name it as such. If the dam or grandam be sister (but which sister must be specified, if there be more than one)

or dam, or grandam of any horse, &c. having a name in the Stud-Book or Racing Calendar, it will be sufficient to mention her as such. If the dam or grandam is not known, the sire of the horse, &c. must be mentioned, together with such other particulars as will be sufficient to identify the animal. If a horse has once appeared in the Racing Calendar by a name and his pedigree, it will be sufficient afterwards to mention him by his name only, even though he has never started. If the dam was covered by more than one stallion, the names of them all must be mentioned.

18. If any horse, &c. shall be named or entered without being identified as before directed, he shall not be allowed to start in the race, but his owner shall be liable to pay the forfeit, or, if a play or pay race, the whole stake. All bets on a horse so disqualified for starting shall be void.

19. No person who has once subscribed a stake shall be allowed to withdraw his name, and no nomination shall be altered in any respect, after the time of closing, without the consent of all the parties in the race being first obtained.

20. No nomination shall be received or considered as valid, so as to entitle the person naming to start his horse, &c. unless he shall, before the time of the closing of the stake named for, have paid up all arrears of stakes and forfeits; but he shall be liable to pay the forfeit of the stake so named for, if he shall previously have been a subscriber to the stake. All bets on a horse so disqualified for starting shall be void.

21. In every sweepstakes in which there shall be any allowance of weight to the produce of untried horses or mares, such allowance shall be claimed on the article by each subscriber before the expiration of the time of naming: and if not so claimed, no allowance shall be made, even though the horse or mare should prove to have been untried at the time of naming.

22. *Respecting Stakes and Bets.* All stakes for matches, subscriptions, and sweepstakes, shall be made before the hour of starting for the first race of the day, in cash, bank bills, or banker's notes, payable on demand, and be paid into the hands of the person appointed by the stewards to receive the same: and in default thereof by any person, he shall pay the whole stake as a loser, whether his horse come in first or not, unless such

person shall have previously obtained the consent of the party or parties with whom he is engaged, to his not staking. But this rule is not to extend to bets, which are to be paid and received as if no such omission had happened.

23. A day-book shall be kept by the person appointed by the stewards to receive the stakes; in which shall be entered an account of all matches, subscriptions, and sweepstakes, to be run for; and as the different stakes are made, they shall be entered therein as paid.

24. Five pounds per cent. shall be allowed on all forfeits under 100*l.* declared to the keeper of the match-book, at or before ten o'clock the evening before running: and if the forfeit amount to 100*l.* and upwards, 10*l.* per cent. shall be allowed. All forfeits shall be paid before twelve o'clock at night of the day fixed for the race, and on those forfeits which shall not be so paid, the deduction for the timely declaration of such forfeits shall not be allowed.

25. No person, shall start any horse, &c. unless he shall have paid all former stakes and forfeits to the keeper of the match-book, by ten o'clock in the morning of the day on which he intends to start his horse, &c. And this rule is declared to extend to all other places, as well as Newmarket, where races are run and engagements entered into by members of the jockey club. And it is recommended to the consideration of the stewards of other races where members of this club are not amongst the subscribers.

And where any person shall have bought a horse, with his engagements, this rule, as to all the engagements subsisting at the time of purchase, and to be run for subsequently thereto, shall be considered as extending to the purchaser, whether those engagements were entered into by the vender or any other person; and such horse, in whosoever hands he may be, shall not be allowed to start for any race until all the stakes due for such engagements shall have been paid. But in default of payment by the purchaser, the original subscriber to such engagements shall not be exonerated from his liability to make them good.

26. If any bet shall be made from signal or indication, after the race has been determined, such bets shall be considered as fraudulent and void, and shall not be paid. And if any servant belonging to a member of this society shall be found to

have betted from any such signal, or shall be concerned in making any such signal, he shall be dismissed from his service, and no further employed by any member of this society.

27. All stakes and bets, whether expressed to be in guineas or pounds, shall be paid in pounds sterling.

28. All double bets shall be considered as play or pay bets.

29. All bets depending between any two horses shall be void, if those horses become the property of the same person, or of his avowed confederate, after the bets are made.

30. All bets between particular horses shall be void if neither of them happens to be the winner, unless agreed by the parties to the contrary.

31. If a match or sweepstakes be made for any particular day in any race week, and the parties agree to change the day to any other in the same week, all bets must stand; but if the parties agree to run the race in a different week, all bets made before the alteration shall be void.

32. When the riders of any horses brought out to run for any race are called upon, by the person appointed to start them, to take their places for that purpose, the owner of every horse which comes up to the post shall be considered as liable to pay his whole stake, and all bets respecting such horses shall be considered as play or pay bets.

33. *Trials.* No person shall try the horse, &c. of any other person than his declared confederate, without giving notice of such trial, by inscribing the name or proper description of the horse, &c. tried, and the name of his owner, in the trial book, kept at the coffee-room, Newmarket, within one hour after the trial has taken place; or by nine o'clock in the morning, in case the trial should have taken place at an earlier hour; and the hour of running such trial, and also the hour of making the entry, shall be noted in the trial book. And in case any trial shall not be so entered, the groom having the care of the horse running with the trial horse, and being present at the trial, or if not present, then the owner of any horse running with such trial horse, shall forfeit and pay to the stewards of the jockey club, the penalty or sum of 10*l.* for every such offence; but the stewards shall have the power to mitigate such penalty to not less than 5*l.* in case it shall fall upon any groom.

34. Every bet made upon or against

any horse running in a trial, between the time of such trial and the entering of it in the trial book, whether it be entered within the time prescribed or not, shall be void.

35. Every engagement made with any horse, &c. running in a trial, between the time of such trial, and the entering of it in the trial book, whether it be entered within the time prescribed or not, shall not be run, but the owner of such tried horse shall be considered as having declared forfeit and be liable to pay the forfeit accordingly, unless his opponents, or any of them, shall desire to hold him to his engagement. And in case any horse so tried shall have started for and won any race made subsequently to the trial, and before the entry of it in the trial book, his owner shall not be entitled to the stake so won; and, in case he shall have actually received it, he shall pay it back into the hands of the stake-holder, who shall pay it over to the owner of the second horse, or, in case of a match, shall pay it over to the owner of the beaten horse; but if such horse shall have lost such race, his owner shall not be entitled to claim or to be repaid his stake or deposit for such race; and in those cases such disqualification shall attach to the horse, without regard to any change of the property in him; and if, with respect to the disqualification, there shall be any difficulty in ascertaining the horse or horses tried, the owner of the horse or horses so tried, shall be bound, on the request of the stewards, to declare to them which of his horses ran in such trial; and in case he shall decline so to do, the stewards shall have power to fix the disqualification upon any one or more of the horses of such owner, at their option.

36. No notice of trial shall be required where the trial is run at a greater distance than 25 miles from Newmarket.

37. The day, with respect to the engaging of the ground for trials, shall be divided into two periods, that is, previously to eight o'clock in the morning, and subsequently to two in the afternoon, from the first day of the Craven meeting to the end of the Houghton meeting; and previously to nine o'clock in the morning and subsequently to two in the afternoon during the rest of the year. No one stable-keeper shall engage the ground for both those periods on the same day, nor for more than two of those periods in the same week.

38. Notice for engaging the ground

shall, at least one day before the day it is used, be entered in a book to be kept for that purpose at the coffee-room at Newmarket. And no notice or warning shall be deemed sufficient unless given as before directed.

39. If any person shall be detected in watching a trial, or shall be proved to have employed any person to watch a trial, he shall be served with notice to keep off the heath; and if in the employment of any member of the club, or of any groom or rider employed by any member of the club, he shall be dismissed from his service, and not again employed.

40. *The Cup and Whip.* The cup may be challenged for on the Monday or Tuesday in the first spring meeting in each year: to be run for over the B. C. on Tuesday in the first October meeting following, by horses, &c. the property of members of the jockey club, four years old carrying 7st. 11lb. five years old, 8st. 8lb. six years old, 8st. 13lb. and aged, 9st. Each person, at the time of challenging, is to subscribe his name to a paper to be hung up in the coffee-room, at Newmarket, and deliver to the keeper of the match-book the name or description of the horse, &c. sealed up, which shall be kept till six o'clock on the Saturday evening of that week: and if not accepted, or only one challenger, to be returned unopened; but if accepted, or more than one challenger, to be then opened, and declared a match or sweepstakes for 200 sovs. each, play or pay. If the challenge be not accepted, the cup to be delivered to the keeper of the match-book, in the meeting ensuing the challenge, for the person who may become entitled to the same.

41. The whip may be challenged for on the Monday or Tuesday in the second spring or second October meeting in each year, and the acceptances must be signified, or the whip resigned, before the end of the same meeting. If challenged for and accepted in the spring, to be run for on the Tuesday in the second October meeting following; and if in the October, on the Thursday in the second spring meeting following, B. C. weight 10st. and to stake 200 sovs. each, play or pay.

42. *The £1 per cent. Plates.* The stakeholder shall deduct 1l. per cent. from all sums won at Newmarket, in sweepstakes or matches, where the clear sum to be received by the winner, over and above his own stake, shall amount to 100l. or more, (unless the winner shall object to allowing such deduction to be made) and the

money so raised shall be disposed of in the following manner; viz.

Two handicap plates of 100l. each, for four, five, six years old, and aged horses, shall be annually given to be run for; one in the second October meeting, A. F. and the other in the Houghton meeting, from the D. I. And if any horse-keeper shall object to contribute to the above fund, he will not be allowed to start a horse for either of those plates.

43. *The Stake-holder at Newmarket.* The stakeholder at Newmarket shall be allowed to retain out of the stakes in his hands the following fees, for his trouble; viz.

For every match, one pound.

For every plate, one pound.

For every subscription or sweepstakes, where the whole stake exceeds 100l. and does not amount to 1000l. two pounds.

For every sweepstakes, where the whole stake amounts to 1000l. or upwards, five pounds.

44. *Relating to matters not before specified.* If for any plate, sweepstakes, or subscription, the first two horses shall come in so near together that the judge shall not be able to decide which won, those two horses shall run for such prize over again, half an hour after the last race on the same day; the other horses which started shall be deemed losers, and be entitled to their respective places, as if the race had been finally determined the first time.

45. Every person who shall ride for a race at Newmarket, shall be weighed immediately after the same, and shall be allowed 2lb. above the weight specified for his horse to carry, and no more, unless the weight he actually rode be declared as the weight he intended to ride, as herein-after mentioned. The owner of every horse which shall be intended to carry more than 2lb. above his weight, shall, by himself or his servant, declare to one of the stewards, or to the keeper of the match-book, before ten o'clock on the morning of the day on which the race is run, what weight he intends his horse to carry, including the 2lb. allowed, which shall be immediately inserted in the list in the coffee-room. And if any horse shall run in a race, carrying more than 2lb. above his weight, without such declaration having been made, or, if after the race, on weighing the jockey, he shall not prove to have ridden the weight which it was declared the horse should carry, or shall have ridden more than 2lb. above

the weight declared, then such horse shall not be considered the winner of the race, even though he should come in first, but shall be placed as the last horse in the race, and his owner shall pay the stake, as for a beaten horse.

46. The persons appointed by the stewards to weigh the jockeys, shall, immediately after each day's race, report to the keeper of the match-book how much each horse carried, where he carried more than 2lb. above the specified weight. And the keeper of the match-book is, as soon after as may be, to communicate such report to the stewards, or one of them. And the weight each horse actually carried, if more than 2lb. above his weight, shall be published in the first list printed after the race, and also in the account published in the Racing Calendar.

47. Every groom shall have his horse at the post, ready to start within five minutes of the time appointed by the stewards. And every jockey is to be there, ready to start, within the same time. And every groom or jockey making default herein, shall forfeit 5*l.* to be paid to the keeper of the match-book, and by him accounted for to the stewards.

48. The person appointed to start the horses shall mark in his list the time when the horses in each race actually started; and, if there have been any false starts, the first of them shall be considered as the time of starting for that race. And he shall make a report thereof to the keeper of the match-book in the afternoon of the day the races are run. And if any delay beyond the allowed time shall have taken place, he shall state by whom, or by what cause, the delay was occasioned. He shall regulate his watch by the coffee-room clock, which shall be considered as the true time for this purpose.

49. If any horse, &c. intended to be entered for any plate or subscription, where entrance is required, shall be engaged to run on the day of entrance, he shall not be obliged to shew at the time of entrance; but if he have not before run at Newmarket, he shall shew at the place of entrance, within one hour after his engagements are over. But no horse that has before run at Newmarket need be shewn at the time of entrance, or afterwards.

50. When any match is made in which crossing and jostling are not mentioned, they shall be understood to be barred.

51. When any match or sweepstakes shall be made, and no weight mentioned,

the horses shall carry 8st. 7lb. each. And if any weight is given, the highest weight shall be 8st. 7lb.

52. When any match or sweepstakes shall be made, and no course mentioned, the course shall be that which is usually run by horses of the same age as those engaged: viz.

If yearlings, the Yearling Course.

If 2 years old, the Two Years Old Course

If 3 years old, Rowley's Mile.

If 4 years old, Ditch-In. And

If 5 years old and upwards, Beacon Course. And if the horses should be of different ages, the course shall be fixed by the age of the youngest.

53. The keeper of the match-book shall charge the proprietors of such horses as receive forfeit, and shall be excused from appearing, with the same fees for weights and scales, as if they had come over the course.

54. Towards defraying the expense of repairing the course and exercise ground, one guinea annually shall be paid in respect of every race-horse that shall be trained or exercised, or that shall run any private trial or public race thereon. And the same shall be paid by the stable-keeper or servant having the care of such horse, and be charged by him to the owner of such horse. Every such stable-keeper or servant shall, immediately after the Houghton meeting in each year, deliver to the keeper of the match-book at Newmarket, a list of the horses which have been under his care, liable to pay the said charge, and shall then also pay to the keeper of the match-book the money due for each horse.

55. If in running for any race one horse shall jostle or cross another, such horse and every horse belonging to the same owner, or in which he shall have a share, running in the same sace, shall be disqualified for winning the race, whether such jostle or cross happened by the swerving of the horse, or by the foul and careless riding of the jockey, or otherwise, and where one horse crosses the track of another next behind him, it shall be deemed a sufficient cause of complaint, even though he be a clear length, or more, before the horse whose track he crosses, it being desirable that, when once a jockey has taken his ground, he should not prevent any other jockey from coming up, either on his right or left hand. And if such cross or jostle shall be proved to have happened through the foul riding of

the jockey, he shall be disqualified from again riding at Newmarket; or shall be punished by fine or suspension for a time, as the stewards shall think fit; it being absolutely necessary, as well for the safety of the jockeys themselves, as for the satisfaction of the public, that foul riding should be punished by the severest penalties.

56. All complaints of foul riding must be made before, or at the time, the jockey complaining is weighed; and it may be made either by the owner, jockey, or groom of the horse, to one of the stewards, to the keeper of the match-book, to the judge of the race, to the clerk of the course, or to the person appointed to weigh the jockeys.

57. In naming or entering for any race where there shall be any particular conditions required as a qualification to start, it shall be sufficient if the horse were qualified at the expiration of the time allowed for naming or entering; and he shall not be disqualified by any thing which may happen after the expiration of that time, unless so specified in the article; and if any additional weight is to be carried by horses which have won one or more plates or races within the year, it shall be construed to mean the year of our Lord.

58. Where it is made a condition of any plate or subscription that the winner shall be sold for any given sum, the owner of the second horse being first entitled, &c. no other person than one who ran a horse in the race shall be entitled to claim. The horse claimed shall not be delivered till he is paid for; and he must be paid for on the day of the race, otherwise the party claiming shall not be entitled to demand the horse at any future period; but, nevertheless, the owner of the winning horse may insist upon the claimant taking and paying for the horse claimed.

59. When the qualification of any horse is objected to by ten o'clock in the morning of the day of starting, the owner must produce a certificate, or other proper document, to the steward, or clerk of the course, or to the keeper of the match-book, if the case happen at Newmarket, before the race is run, to prove the qualification of the horse; and if he shall start his horse without so doing, the prize shall be withheld for a period to be fixed upon by the stewards, on the expiration of which time, if the qualification be not proved to the satisfaction of the stewards, he shall not be entitled to the prize,

though his horse shall have come in first, but it shall be given to the owner of the second horse. When the qualification of a horse is objected to after that time, the person making the objection must prove the disqualification.

60. It is expected that every member of the clubs at Newmarket, and every person running or training horses at Newmarket, shall consider themselves amenable to these rules, and such others as the stewards may from time to time think fit to adopt for the better regulation of racing at Newmarket. And all trainers, jockeys, grooms, and servants of such persons, are strictly enjoined to observe the same. And if any trainer, jockey, groom, or servant, shall be proved to have been guilty of any infraction of these rules or orders, or of any of them, he will be punished by the stewards, to such extent as they may think the case requires, and in such a manner as they may have power to enforce.

61. All disputes referred to the stewards of the jockey club will be adjudged according to their published rules and orders, where any of them are applicable to the case submitted to them; and where not, according to the established rules of racing.

S. BATSON,  
LOWTHER,  
RICHMOND, } Stewards.

#### ADJUDGED CASES.

*Case 1.* A, B, and C, run for a subscription, the best of heats. A wins the *first* heat, B the *second*.—C's rider, after saving his distance the second heat, dismounts between the distance-post and the end, but remounts, rides past the ending-post, and weighs as usual; starts, and wins the *third* heat, and weighs, without any objection being made.

A, being second the third heat, in a short time afterwards demands the subscription (not knowing till then that C's rider had dismounted) and refuses to start for the *fourth* heat, which B and C run for, and C wins.

It was decided, that no objection having been made to C's starting for the third heat, he was entitled to the prize.

*Case 2.* The winner of a plate, whose horse had distanced all the others, applied for the stakes or entrance money, which was advertised to be paid to the second best horse that won a clear heat—one of the distanced horses had won the first heat.

It was decided, that the winning horse cannot be deemed the second horse, and therefore was not entitled to the stakes; and all the others being distanced, no other person could claim them.

*Case 3.* A gold cup, &c. for horses that never won.

A	.	.	.	1
B	.	.	.	2
C	.	.	.	3

The owner of B claimed on the ground of A's disqualification, he having, the preceding year, won a clear heat at Chelmsford, to entitle him, according to their articles, to the stakes or entrance-money.

It was decided that A was not disqualified, the term "winner" applying only to the horse that beats all the rest.

*Case 4.* Whether a horse, having won a sweepstakes of 23gs. each, (3 subscribers) is qualified to run for a 50l. plate, expressed to be for horses that never won plate, match, or sweepstakes, of that value?

It was decided, that it was the practice, in estimating winnings, to consider the clear sum gained only, and consequently to exempt the stake of the proprietor; the horse, therefore, which had won a sweepstakes of 46gs. only, viz. two stakes of 23gs. each, was not thereby disqualified for the 50l. plate above-mentioned.

*Case 5.* Mr. Baird having entered two horses for the Kings's plate at Newcastle, in 1793, and won it with Sans Culotte, (his other horse not starting) the owner of the second horse objected to his receiving the plate, on the ground that he was disqualified by having *entered* two horses.

It was decided, that Mr. Baird was entitled to the plate.

*Case 6.* A betted B, that a mare should trot a mile in five minutes, in four minutes and a half, and in four minutes; all which, it was stated, she won with ease; but B measuring the distance after the races were over, found it was short of a mile by four yards.

It was decided, that as no objection was made to the measure of the course before starting, and the mare having performed the distance set out, and not objected to, A won all the bets.

**JOCKEYS.** We extract the following from that interesting little book, the "Turf Expositor."—

"Jockeys (observes the author) I regard, in the aggregate, as honest men than trainers, unless, indeed, where the two professions are united; and, when I behold a man thus circumstanced, I can-

not help viewing him in the light of a Janus of Mischief, calculated to put in practise every species of trickery, on both sides the question.

Jockeys may be divided into two, if not three, classes: namely, the southern jockeys, the northern jockeys, and the *dirty* jockeys. The first class are those which are seen at Newmarket, Ascot, Epsom, and indeed in most of the races in the southern counties, and also at Doncaster. The second class attend the Yorkshire meetings, and what, for the sake of distinction, I will call the northern circuit. The third or *dirty* class, are met with still farther to the north, in Westmoreland, Cumberland, &c. and are remarkable for their slovenly, dirty, and unworkmanlike appearance:—it is no uncommon occurrence to see these wretched apologies for jockeys (at Kendall for instance) ride in dirty jackets, dark greasy corduroys, and gaiters of a similar complexion. Mr. Thomas Simpson's jockey frequently appears thus, though Mr. Simpson is wealthy and highly respectable; but evidently not very scrupulous on the score of cleanliness. The southern jockeys, much to their credit, appear on horseback with a neatness and cleanliness bordering upon elegance; and their performance is, for the most part, of a superior order—superior, in fact, to their rivals of the north; they are illiterate, ignorant men, with little exception; though, in private, they affect a mysterious but plebeian, importance, and would willingly be thought a sort of semi-gentlemen, which, however, their very attempt to assume such a character renders impossible. There is much less of this ridiculous and ignorant affectation about the northern jockeys, who yet seem, it must be confessed, not nearly so anxious about their appearance on horseback (as far as relates to the advantage of dress;) as their brethren of the south.

The question next arises as to which are the best workmen. The southern, beyond a doubt; that is, speaking generally: but, it must be admitted, that there are some excellent northern jockeys, who would lose little by the comparison with either Chifney, Robinson, Dockeray, or any of the most favourite riders of the present day. Buckle is now grown old, and does not often appear; otherwise, I should place him at the head of the list. H. Edwards must be classed, I imagine, amongst the northern jockeys; he has a good seat, good hands, and a good head;

and is altogether an excellent rider; I am doubtful if his superior is to be found. T. Shepherd, a northern jockey, has a good head, and I have always admired his riding; I think his abilities have generally been much underrated. Lear is a promising young northern jockey; but he must be careful not to let his self-opinion and overbearing temper supersede the plain uncultivated sense he possesses. Templeman is what may be called an improving jockey: he has a good seat, and I have frequently been much pleased with his performances. He rode Dr Faustus (Sir T. Stanley's) very well at the Liverpool summer meeting (1829), and I thought won the cup—I was not singular in this opinion: the judge, however, decided in favour of Velocipede. I never recollect observing a horse better managed than Forth managed his own horse Frederick, when running this year (1829) at Epsom, for the Derby. He had betted to a considerable amount on Exquisite (also his own horse, and came in second) particularly with Mr. Crockford; but shifted his money, the evening before running, on Frederick, and thus became a winner to a very considerable amount. There are many very awkward jockeys, possessing but very slender requisites for the profession which they have embraced; to point them out, however, by name, would appear ill-natured and invidious.

It is some dozen years or more since "Old Billy Pierse" quitted the avocation of a jockey. This man I always considered as a very superior rider—as one of the best I ever saw. In stature, he was one of the shortest of his fraternity: but he was a sort of dwarf Hercules: he was able to give his horse a pull without any perceptible movement of his body; and, of all the jockeys I ever saw, not one sat so steadily upon his horse. He never acquired the fame of Chifney; though there are those who think his merits were equal, if not superior, to that celebrated jockey:—such is the opinion of one gentleman, in particular, whose superior judgment I have frequently experienced, and very much admired.

What I have denominated the "dirty jockeys" are little worthy of consideration. They are very indifferent riders, but made up of trick and cunning; and ready at any time to put in practice their sinister arts for the purposes of deception, swindling, and fraud.

There is another class of jockeys, which

cannot be passed over in silence:—I allude to what are called *gentlemen riders*, a term grossly misapplied in many instances. I have always considered it a mistaken notion for gentlemen to appear on the race course in the character of jockeys:—it cannot be in imitation of the heroes of old, who were so emulative in the Olympic games. There is no accounting for taste; so the circumstance of gentlemen converting themselves into jockeys, where *real gentlemen* only are concerned, might be excusable, or passed over with the slightest possible reprehension; but the business has been so subjected to abuse, that, I have not the least doubt, were this description of jockeyship entirely superseded, it would give very general satisfaction to the true friends of the turf. In the first place, with the exception of Lord Wilton, Mr. White, and some others, there are few gentlemen but what make a poor, or perhaps ridiculous, figure in riding a race. When gentlemen are to ride, it seldom happens that the patience of the multitude is not put to the test: if the preparations for gentlemen riders are not more complex than those of the professed jockeys, they cannot be either so well defined, or so direct, since they occupy a period of time, of at least six times the duration. But this is by no means the worst of the business:—the system is liable to very gross abuse; and a class of men contrive to insinuate themselves into it, who have very meagre pretensions, indeed, to the character of *gentlemen*, and whose operations are, for the most part, merely a cloak for the basest purposes. I have often been surprised, that those genuine or sterling gentlemen who choose to contend in the race are not more scrupulous as to the persons in whose company they thus appear: accustomed as they are to the turf, they cannot be unconscious, surely, that men frequently are seen as gentlemen riders, who are not only destitute of every honourable feeling, but whose exertions are made in furtherance of a system of swindling, base, degrading, and utterly incompatible with the best interests of the turf. Also, a number of these men cannot come fairly under the description of amateur riders, since they go from race to race throughout the season, and are in the constant habit of riding, which they understand as well as the regular jockeys: what chance has a mere amateur against such competitors?

## COLOURS WORN BY JOCKEYS.

Lord Ailesbury . . .	scarlet body, yellow sleeves, black cap.
Lord Anson . . .	sky blue, with black cap.
Mr. Batson . . .	crimson and white stripe, black cap.
Mr. Beardsworth . . .	crimson.
Mr. Benson . . .	white body, mazarine blue sleeves, chequered cap, blue and white.
Sir J. Beresford . . .	pink and white.
Mr. Berkeley Bond . . .	celestial blue body.
Mr. Biggs . . .	green, with red cap.
Gen. Sir J. Byng . . .	orange body, light blue sleeves, and black cap.
Lord G. H. Cavendish . . .	orange.
Mr. L. Charleton . . .	red and white stripe, with black cap.
Lord Clarendon . . .	blue, with red collar and cap.
Lord Cleveland . . .	pink and black stripe, with black cap.
Mr. Clifton . . .	yellow and snuff brown, broad stripe round the body.
Mr. Gilbert Crompton . . .	orange satin.
Mr. Fulwar Craven . . .	purple, with orange cap.
Col. Cradock . . .	blue body and cap, with white sleeves.
Lord Derby . . .	black, with white cap.
Mr. Dickinson . . .	scarlet body, with white sleeves and cap.
Mr. Dilly . . .	red, with white cap.
Mr. Douglas . . .	yellow body, black sleeves and cap.
Mr. Dundas . . .	light blue, with orange cap.
Lord Egremont . . .	dark green, with black cap.
Lord Exeter . . .	light blue and white narrow stripe, and black cap.
Mr. A. Farquharson . . .	red, with black cap.
Lord Fitzwilliam . . .	grass green satin, with black velvet cap.
Lord Foley . . .	green and white stripe.
Mr. Garforth . . .	light blue.
Mr. Gascoigne . . .	black and white.
Mr. Gauntlett . . .	crimson, with white cap.
Mr. Giffard . . .	light blue and yellow, with black cap.
Mr. Goddard . . .	white body, mazarine blue seams, sleeves and cap.
Mr. Ormsby Gore . . .	scarlet, with purple and velvet cap.
Duke of Grafton . . .	scarlet.
Mr. Greville . . .	purple, with black cap.
Lord Grosvenor . . .	} yellow, with black cap.
General Grosvenor . . .	
Mr. Gully . . .	violet, with white cap.
Mr. Haffenden . . .	crimson body and cap, black sleeves.
Mr. Heathcote . . .	crimson, with black cap.
Mr. Holyoake . . .	white, with gold buttons.
Mr. Houldsworth . . .	green and gold, with yellow cap.
Mr. Hunter . . .	white body, crimson sleeves, and crimson cap tied with white riband.
Lord Jersey . . .	dark blue and buff stripe, black cap.
Mr. Irby . . .	orange, with white cap.
Mr. R. Jones . . .	black body, white sleeves and black cap, tied with white riband.
Mr. Johnson . . .	red, purple cap.
Colonel King . . .	mazarine blue, crimson sleeves, and cap.
Lord Durham . . .	blue and buff, with black cap.
Duke of Leeds . . .	chocolate, with black cap.
Lord Lowther . . .	white and yellow stripe, with red cap.
Lord Lynedoch . . .	light blue and crimson stripe.
Mr. Maberly . . .	crimson, with white cap.
Mr. Maule . . .	orange, with mazarine blue cap.
Mr. F. Mills . . .	black and white broad stripe.
Mr. J. Mills . . .	white, with red cap.

Mr. R. Milnes . . . .	black body, pink sleeves, with white cap.
Lord Milton . . . .	green.
Mr. Molony . . . .	black and white stripe across the body, light blue cap.
Sir D. Moncrieffe . . . .	white.
Sir T. Mostyn . . . .	yellow, with black cap.
Lord Mountcharles . . . .	French grey, with scarlet cap.
Mr. Mytton . . . .	green and white, black cap.
Mr. Nowell . . . .	rose colour, with black cap.
Lord Orford . . . .	orange body, black sleeves, and white cap.
Mr. Payne . . . .	black and white broad stripe.
Hon. E. Petre . . . .	black body, pink sleeves, and black cap.
Mr. R. Petit . . . .	black and white stripe across the body, blue cap.
Mr. Peel . . . .	orange.
Sir George Pigot . . . .	yellow, with black cap.
Duke of Portland . . . .	white, with black sleeves and cap.
Hon. T. O. Powlett . . . .	deep yellow, with purple cap.
Mr. Prendergast . . . .	black body and red sleeves.
Mr. Pringle . . . .	azure and white stripe, cap quartered.
Lord Queensberry . . . .	deep red, with black cap.
Mr. Delme Radcliffe . . . .	blue, trimmed with scarlet, and black cap.
Mr. Radclyffe . . . .	yellow, with black cap.
Mr. Ramsbottom . . . .	purple body, orange sleeves and cap.
Mr. Rawlinson . . . .	pink, with black cap.
Duke of Richmond . . . .	yellow, with red cap.
Mr. Riddell . . . .	blue and yellow.
Sir M. W. Ridley . . . .	pink body and cap, white sleeves.
Mr. Ridsdale . . . .	sky blue body, white sleeves and cap.
Mr. Roberts . . . .	white, with scarlet and white cap.
Mr. J. Rogers . . . .	white and yellow stripe, with red cap.
Mr. Rush . . . .	black, with red cap.
Mr. Russel . . . .	white, with gold buttons.
Col. Russel . . . .	blue and buff stripe.
Duke of Rutland . . . .	light blue, purple sleeves, black cap.
Mr. Sadler . . . .	white body, scarlet sleeves, black cap.
Lord Scarborough . . . .	sky blue and white stripe.
Lord Sefton . . . .	white body, yellow sleeves and cap.
Sir J. Shelly . . . .	black, with white cap.
Lord Sligo . . . .	white, with crimson sleeves.
Mr. H. Smith . . . .	white, with yellow cap.
Lord Southampton . . . .	dark blue and white quartered—cap, dark blue.
Mr. Sowerby . . . .	light blue.
Sir T. Stanley . . . .	blue body, yellow sleeves, blue and yellow cap.
Mr. Scott Stonehewer . . . .	yellow.
Lord Stradbroke . . . .	pale blue satin.
Sir Tatton Sykes . . . .	orange body, purple satin sleeves, cap.
Mr. Thompson . . . .	crimson, black cap.
Lord Tavistock . . . .	blue and buff stripe.
Mr. Thornhill . . . .	white body, scarlet sleeves, white cap.
Mr. Thornhill (Oxon) . . . .	black, with orange cap.
Mr. Tomes . . . .	black body and cap, light blue sleeves.
Mr. Vansittart . . . .	white, with blue cap.
Lord Verulam . . . .	white, with black and yellow down the seams, and black cap.
Mr. Udny . . . .	pea green.
Mr. R. W. Walker . . . .	pink, with black cap.
Lord Warwick . . . .	brown body, white sleeves, and cap.
Mr. Watt . . . .	harlequin.
Mr. West . . . .	mazarine blue, with black cap.
Lord Wharnccliffe . . . .	white.
Mr. White . . . .	pink body, black sleeves, and cap.
Mr. Wilson . . . .	light blue, trimmed with black, and black cap.

Col. Wilson . . . .	green and red stripe.
Mr. R. Wilson . . . .	white, with green and velvet cap.
Lord Wilton . . . .	dark blue and white stripe, black cap.
Sir W. Wynne . . . .	crimson and white quartered, with white cap.
Mr. Wadham Wyndham	dark blue body, yellow sleeves and cap.
Major Yarrowburgh . . . .	dark blue, with red cap.
Mr. Yates . . . . .	orange.
Col. Yates . . . . .	purple, with orange cap.

**JOCKEYSHIP** is a term sometimes used in a metaphorical sense, alluding to the dealings of individuals, where one, by a superior degree of knowledge, cunning, artifice, or chicanery, obtains in *a bargain* considerable advantage over the other. Its principal signification, however, in its literal meaning, and frequent use, applies more particularly to the peculiar excellence, or personal ability, of Jockeys, whose avocation it is to ride horses for the different plates and prizes at Newmarket, and various other parts of the kingdom. The great and leading qualifications which constitute the predominant traits of distinguished jockeyship, are to acquire a complete knowledge of the prevalent points, speed, temper, mouth, and perfections or defects, of the horse before starting; to ascertain, as well as it can be accomplished, a tolerable idea, whether it will be most in his favor to insure the whip-hand, or decline it; to take the lead, or leave it, and wait upon his adversary; whether to make play, or to lay by: all these, and a variety of other contingencies dependent upon judgment, as well as a still longer list, which must ever be equally dependent upon the sole

effect of chance, seem combined to render jockeyship a very arduous task.

**JOHN BULL.** The name of a horse of much celebrity both as a racer and a stallion; having been deemed, by the best judges, a horse of the greatest strength, and the most beautiful and corresponding symmetry, ever produced in this kingdom. He was bred by the late Lord Grosvenor; foaled in 1789; got by Fortitude, dam (Xantippe) by Eclipse; her dam (Grecian Princess) by Williams's Forester, &c. &c. Monday, in the Craven Newmarket meeting, 1792, when three years old, he won the great produce stakes of 200 guineas each, half forfeit, across the flat, 35 subscribers; beating Ormond, Hotspur, Whisky, St. Paul, Lucifer, and three others. At Epsom, in May, the same year, he won the Derby stakes of 50 guineas each, 32 subscribers; beating Speculator, Bustard, Lyricus, St. George, Whisky, and the Duke of Queensbury's colt by Pharamond. Soon after which, sustaining an injury, he paid 300 guineas forfeit to Lord Foley's Vermin, and became a stallion, 1796, at 20 guineas a mare.

**IRISH GREYHOUND, OR WOLF DOG.** This animal might perhaps be considered as the first of the canine race; but it is now very rare, even in the only country in the world where it is to be found, and is rather kept for show than use, there being neither wolves, nor any other formidable beasts of prey in Ireland, that seem to require so powerful an antagonist. The Irish greyhound or wolf dog is therefore bred up by such persons as choose to keep him as a curiosity. He is beautiful and very majestic in appearance, being the largest of the dog kind to be seen in the world. Goldsmith says, "the largest of those I have seen (and I have seen above a dozen) was about four feet high, or as tall as a calf of a year old. He was made extremely like a greyhound, but rather more robust, and inclining to the figure of the French *matin* or the great Dane. His eye was mild, his colour was white, and his nature seemed heavy and phlegmatic. This I ascribed to his having been bred up to a size beyond his nature; for we see in man and all other animals, that such as are overgrown are neither so vigorous, nor so alert, as those of a more moderate stature. The greatest pains have been taken with

## IRISH GREYHOUND

these to enlarge the breed both by food and matching. This end was effectually obtained indeed, for the size was enormous; but as it seemed to me at the expense of the animal's fierceness, vigilance, and sagacity. However, I was informed otherwise; a gentleman who bred them assuring me that a mastiff would be nothing when opposed to one of them, who generally seized their antagonist by the back; he added, that they would worry the strongest bull-dog to death in a few minutes. But their strength did not appear either in their figure or their inclinations; they seemed rather more timid than the ordinary race of dogs; and their skin was much thinner, and consequently less fitted for combat. Whether, with these disadvantages, they were capable, as I was told, of singly coping with bears, others may determine; however, they have but few opportunities in their own country of exerting their strength, as all wild carnivorous animals there, are only of the vermin kind. They were once employed in clearing the island of wolves, which infested it in great plenty; but these being destroyed, the dogs are also wearing away, as if nature meant to blot out the species, when they had no longer any service to perform."

From other writers on the subject we are given to understand, that the Danish dog, the Irish greyhound, and the common greyhound of this country, though they appear so different, are but one and the same race of dog. The Danish dog is said by Buffon to be but a more corpulent Irish greyhound; and that the common greyhound is the Irish greyhound rendered thinner and more fleet by experimental crosses, and more delicate by speculative culture; for these three different kinds of dogs, though perfectly distinguishable at first sight, differ no more, comparatively, from each other than three human natives, of Holland, Italy, and France; and by the same mode of argument, he justifies the supposition, that, had the Irish greyhound been a native of France, he would have produced the Danish dog in a colder climate, and the common greyhound in a warmer one; and this conjecture, he observes, is absolutely verified by experience, as the Danish dogs are brought to us from the north, and the greyhounds from the Levant.

Having given the opinions of others on this ambiguous subject, we will venture to express our own. From those specimens of the Irish greyhound which have fallen under the observation of the writer, he has much reason to believe that they were originally produced by crossing the mastiff and the common greyhound; but the immediate offspring of such a conjunction would not be the animal in question, as it would be too heavy and sluggish, or partake too much of the nature of the mastiff; another cross of the greyhound, however, that is, two thirds of the greyhound and one third of the mastiff, would give us something very like the Irish greyhound or wolf dog: the strength of the mastiff is thus decreased; but this seems to be more than compensated by the great increase in activity, and the keenness of the bite.

But nothing can be more erroneous than the supposition, that the Irish greyhound is the precise kind of dog frequently introduced in the productions of Rubens, Snyders, and others, as well as in the

popular and well known prints of Redinger, where dogs are represented in contact with the wild boar. The German boar dog is a very different animal from the Irish greyhound; and indeed the latter has a very strong resemblance to the tough, wire-haired greyhound frequently seen in the north of England and in Scotland, only larger and more powerful.

**ITCHING.** Horses are sometimes observed to labour under a severe itching, or external irritation, which keeps them in a kind of perpetual disquietude; biting such parts as they can get at with the mouth, and rubbing those more remote against such parts of the stall as are most convenient. In cases of this description, the blood does not possess a proper or just equalization of the component parts indispensibly necessary to the standard of health. Permitted to continue and increase, it extends its progress from a simple itching, in the first instance, to scurfy eruptions, scaly exfoliations, or partial loss of hair; bearing the external appearance of surfeit, degenerating, by degrees, to inveterate mange, or confirmed farcy. Bleeding should be resorted to, the system improved, and the circulation enlivened, by an invigoration of the frame: the property of the blood should be enriched by an alteration in the quality of the food. A great deal of substantial dressing should be adopted in the stable, and regular gentle exercise out.

**JUCKING.** Partridges are said to *juck* when they congregate for the night.

**JUDCOCK, or JACK SNIPE.** This bird is scarcely half as large as the common snipe, though its haunts are similar; but it is more rare, and will generally lie so close as to suffer itself almost to be trod upon before it will rise; its flight is seldom distant; and though it does not seem to fly so fast as the common snipe, yet it presents a more difficult shot; or, at least, so the writer has found it. As it rarely flies far, so it may be followed and fired at as often as necessary; and instances have been known where one of these little birds has furnished amusement for a sportsman during the whole season!

The jack snipe will scarcely weigh two ounces; and it is in some parts of the country, distinguished by the name of the *half snipe*. The length of this bird is eight inches; the bill is something more than an inch and a half long, and black; crown of the head tinged with rust colour; a black streak divides the head lengthways from the base of the bill to the nape

of the neck; over each eye a yellow streak passes to the hinder part of the head; neck varied with white, brown, and pale red; scapulars narrow, very long, brown, and margined with yellow; the rump of a glossy bluish purple; belly and vent, white; the greater quill feathers, dusky; tail, brown, with tawny edges, and consisting of twelve pointed feathers; the legs are of a cinereous green.

This bird breeds in our marshes; and lays five or six eggs, of a dirty olive colour.

**JUDGE.** A person appointed to place the horses in a race. I have frequently known dissatisfaction to arise from the manner in which the judge has placed the horses; for instance, at the last Epsom races (1829) the first race, the first day, was very closely contested by Conrad and Fleur de Lis. I was nearly opposite the winning post, and felt no hesitation in supposing Conrad the winner; I heard great numbers express their opinion to the same effect. The judge decided otherwise. At the Liverpool meeting in July, 1829, the gold cup was decided in favour of Velocipede, though many persons insisted that Dr. Faustus was the winner. Templeman, who rode Dr. Faustus, unhesitatingly declared his unqualified conviction that he won the race. Now, since no person can tell so exactly which wins as the judge; from the situation in which he is placed, I am very willing to suppose, that, in both cases, the decision was correct. Many other instances might be adduced, but as they merely form a catalogue of unmeaning repetition, I shall not state them.—However, a judge, in order to be master of his business, or qualified for the important office which he undertakes, should be generally acquainted with the jockeys, the colours, and also the horses, particularly when they come within distance, or he will find it a difficult matter, should the race be finely contested, to give a correct decision—a decision satisfactory to his own mind.—A judge should abstain from betting, if he wish to avoid suspicion.—**TURF EXPOSITOR.**

**JUGGED.** A technical term with the horse-dealing fraternity; and implies a horse's having tumefactions under the jaws. But when used in a more serious and emphatic sense, it is to convey an idea, that the horse is infected with the glanders.

**JUNE.** If this month (and also the preceding) be fair and dry, an abundance of winged game may be expected. Much rain is highly injurious to young birds; while dry weather is not only more con-

genial to their nature, but furnishes food in abundance, which principally consists of insects.—Young grouse are on the wing.

**JULY.** Early mowing is destructive to the incubation of partridges and pheasants; for, although many young birds (the greater part) are brought forth prior to this period, yet the eggs of yearling birds are seldom hatched before July.—Young grouse are strong on the wing.

## K

**KEEPERS** are of different kinds, acting under different appointments, as servants of the crown, or of individuals. There are forest keepers, park keepers, and game keepers, whose employments are distinct and separate from each other. It is the province of the first to superintend and protect the deer in any one of his majesty's forests to which he is appointed, and to become a principal instrument of enforcing the laws enacted for its preservation, against depredators of every description. Park-keepers are retained in the service of noblemen and gentlemen who have parks stocked with deer; their employment is principally to superintend, preserve, and regulate the stock, as well as to kill bucks, does, and fawns, according to the season, when required for the table; which can never be done by any park-keeper of the crown without a proper warrant previously issued from superior authority for that purpose.—Game-keepers are employed in various forests, parks, chases, free warrens, and manors, to protect, preserve, or kill any kind of game upon the particular place or manor for which they are appointed; to execute and enforce all such manorial rights and privileges within the department, as may be submitted to their delegation; but for further information on the subject the reader is referred to the article **GAME-KEEPERS**, page 352.

**KENNEL** is the place where hounds are kept; and upon the judicious construction of which their health, safety, and preservation mainly depend. We have, under the article of **FOX HUNTING**, described the kennel, and refer to it accordingly. Among the most extensive, as well perhaps as the most approved, kennels, are those of the Duke of Bedford at Woburn Abbey; the Duke of Richmond's at Godwood in Sussex; and Sir

William Rowley's at Tendring Hall, Suffolk. The erection of the Duke of Richmond's kennel is said to have cost £10,000.

**KENNEL.** As we say a hare's seat or form, we say a fox's kennel: a fox being found by the hounds in drawing cover, he is then said to be unkennelled.

**KIBBLE.** The first remove from the southern-hound is the *kibble*. See the article **HOUNDS**.

**KIBES**, in horses, are the cracks which appear in the heels during the severity of the winter season, and are much more the consequence of neglect, or a want of knowledge in the stable discipline, than the effect produced by changes in the weather. They proceed mostly from being left with wet legs, which, in very cold or frosty weather, occasions such a tightness and rigidity of the skin, that, when brought into sudden and brisk action, it bursts asunder, (in a greater or less degree,) according to the texture of the skin, or the constitutional irritability of the horse. These soon become exceedingly painful; and if the weather should repeatedly vary from short frosts to alternate thaws, and the horse continue in use, the constant insinuation of the sharp particles of small gravel and sand of the dirty roads, is productive of such excruciating sensations, that the animal refuses food, and does not lay down for many days and nights in succession: when even gently compelled to move, he lifts up the limb in so much misery, that it is with the greatest reluctance he brings it again to the ground. Cure may be effected by poultices made of linseed powder, milk, and a little olive oil, applied immediately after comfortable softenings with warm gruel, and a small sponge: an alterative powder in a mash, nightly, and the use of camphorated spermaceti liniment, night

and morning, when the poultices are left off, will be found greatly to assist the general intent, letting the horse rest.

**KIDNEYS.** The distinguishing symptoms of diseased kidneys in the horse, are a palpable weakness of the hind part of the back and loins, a painful sinking of those parts upon pressure, a difficulty of staling, which is generally voided partially in small quantities, and frequently with short groans of internal disquietude: in slight affections, the urine is white, but turbid; in severe cases, very high coloured, as if tinged with blood: there is mostly a heaviness of the eyes, debility of body, a loathing of food, and a tendency to symptomatic fever. From whatever cause an injury may arise, or from whatever state of the body a disease of the parts may proceed, bleeding largely is the first step to speedy relief, and the prevention of danger. The quality and quantity of medicine must be regulated by the shades, as well as the duration, of the disorder, according to consequences liable to ensue. Warm clysters of gruel and olive oil occasionally; mashies, made of ground malt and bran, for food; and thin gruel for drink, in which gum-arabic should be dissolved, to lubricate the passages, and sheath any asperity with which the parts may be affected. Should the weakness of the loins increase, the difficulty of staling continue, the urine become more thick and foetid, the strength more reduced, and the frame emaciated, one or both the kidneys may be considered in a state of ulceration, and cure cannot be expected.

**KINDLE.** A doe rabbit is said to kindle when she brings forth young.

**KING FERGUS.** The name of a horse bred by the late Colonel O'Kelly; he was foaled in 1775; was got by Eclipse, dam (Tuting's Polly) by Black-and-all-Black, grand-dam by Tartar, great grand-dam by Old Starling. He was of great celebrity, and continued for many years a stallion of the first eminence. He was the sire of a great number of good racers, amongst which were those celebrated runners Hambletonian, Overton, Beningbrough, Sir Solomon, Warter, Johnny, Garswood, &c. &c.

**KING'S PLATE.** Those called king's plates, are a free gift from his majesty of 100 guineas each; and, it is believed, were originally granted as a means of exciting such a degree of emulation, as would probably tend to national advantage, by improving the breed of horses in general;

as well as to afford an annual pecuniary advantage to such cities and towns as enjoy the royal favour.

**KING'S PLATE ARTICLES.**—It is his majesty's command, that these following Rules be observed by the owners and riders of all such horses, mares, and geldings, as shall run for his majesty's plates at Newmarket.

1. Every horse, mare, or gelding, that runneth for the said plates, shall carry twelve stone, fourteen pounds to the stone, three heats.\*

2. Every person that putteth in a horse, mare, or gelding, for the said plate, is to shew such horse, mare, or gelding, with the marks, name, and name of the owner, to be entered at the king's stables in Newmarket the day before they run; and shall then produce a certificate under the hand of the breeder, that his horse, mare, or gelding be no more than ——— years old the grass before.

3. Every horse, mare or gelding, that runneth, is to start between the hours of one and four in the afternoon; and to be allowed half an hour between each heat to rub.

4. Every horse, mare, or gelding, that runneth on the wrong side of the posts or flags, or is distanced, in any of the heats, shall have no share of the said plates, nor be suffered to run any more.

5. The horse, mare, or gelding, that winneth any two heats, winneth the plate; but if three several horses, mares, or geldings, win each of them a heat, then those three, and only they, to run a fourth heat, and the horse, mare, or gelding, that winneth the fourth heat, shall have the plate.

6. And each horse's, mare's, or gelding's place, as he or they come in, by the ending-post, each heat, as first, second, third, &c. shall be determined by such judges as shall be appointed for that purpose by the Master of the Horse. And in case any horse, mare, or gelding, shall be then, or after, proved to be above the age of ——— years the grass before, the owner or owners of such horse, mare or gelding, shall be made incapable of ever running for any of the king's plates hereafter.

7. As many of the riders as shall cross, jostle, or strike, or use any other foul play, as shall be judged by such person or persons as shall be appointed by the Master of the Horse, such rider shall

---

\* By order, it is altered to one heat, and different weights are appointed.

BIRDS, ETC. *Plate V.*

KNOT, *p.* 517.

OTTER, *p.* 573.

PLOVER, or LAPWING, *p.* 640.

be made incapable of ever riding any horse, mare, or gelding, for any of his majesty's plates hereafter; and such owner shall have no benefit of that plate; but such owner may be permitted to run any horse, mare, or gelding, for any other of his majesty's free plates hereafter.

8. Every rider shall, immediately after each heat be run, be obliged to come to the usual place of weighing, with his horse, mare, or gelding, then and there to alight, and not before, and there to weigh to the satisfaction of the judges appointed for that purpose.

9. And in case of neglect or refusal thereof, such owners and riders shall be immediately declared incapable of running or riding any more for this or any of his majesty's plates hereafter.

10. And in case any difference shall arise relating to their ages, or in their running, or to these his majesty's orders, &c. the same to be determined by such person or persons as shall be appointed by the aforesaid Master of the Horse.

\*\*\* *These Articles will continue in force for succeeding years, unless directed to the contrary by his majesty.*

✂ A slight alteration will be observed in the Eighth Rule, as to the place where the jockey is to dismount—this is made with the sanction of his Grace the Duke of Leeds, Master of the Horse to his Majesty.

*Form of a Certificate of having won a King's Plate.*

These are to certify, that his Majesty's Plate of a Hundred Guineas was won at \_\_\_\_\_ the \_\_\_\_\_ day of \_\_\_\_\_ 183 , by \_\_\_\_\_'s \_\_\_\_\_ horse called \_\_\_\_\_ A. B. Steward, \_\_\_\_\_ C. D. Clerk of the Course.

**KNOT, THE.** This bird, which frequents the fens, is said to have been a favourite dish with Canute, king of England; and Camden observes, that its name is derived from the monarch Knute or Knout, as he was called, which, in process of time, has been changed to Knot. These birds are caught in Lincolnshire, and other fenny counties, by nets, into which they are decoyed by stale birds, carved and painted so as to represent themselves, and placed within the range of the nets: their numbers are so considerable that Mr. Pennant states fourteen dozen to have been taken at once. They are fattened in the same way as the ruffs, and by some are supposed to excel that bird in flavour. The season for taking them is from

E. } \*Lord Lieutenant  
of the County.

*To his Grace the Duke of Leeds,*

*Master of the Horse to his Majesty.*

[The signature of the Lord Lieutenant alone is sufficient, but that can seldom be obtained without first producing to him a certificate signed by the Steward and Clerk of the Course.]

N. B. The certificate, when properly signed, is payable at sight to the winner of the plate (or to any other person, if endorsed by the winner) at the office of the Clerk of his Majesty's Stables, in the Royal Mews, Pimlico.

The plates at Chester and Edinburgh, and the hunter's plate, at Ascot, being given from a different fund, the certificates are to be addressed to the Keeper of the Privy Purse, and presented for payment at the Duchy of Cornwall Office, Somerset House.

\*\*\* Since the alteration in the act of parliament respecting stamps for receipts, the Clerk of the Stables requires the person presenting a certificate for payment, to provide a receipt stamp of the proper value, which at present is *two shillings and sixpence*.

**KNEE OF A HORSE,** is the central joint of the leg, where the fore-thigh is united to the shank-bone. Its formation is of such strength, that a lameness, by twist, distortion, or any other injury, is hardly ever sustained in this part, but by the accident of falling; which frequently happens, and, if attended with a blemish, very much reduces the previous value of the horse. Loss of hair upon the knees, when not too severely affected, may be restored by a daily application of neat's foot oil. See **BROKEN KNEES**.

\* If the Lord Lieutenant be *officially* out of the kingdom, the signature of the Vice Lieutenant is admissible. The certificates for the Ascot-Heath plates must be signed by the Master of his Majesty's Hounds, instead of the Lord Lieutenant.

August to November, after which they in general disappear with the first frosts. The weight of the knot is four ounces and a half, length from nine to ten inches, breadth from sixteen to twenty inches. Bill one inch and a quarter, black at the tip, and dusky ash fading into orange towards the base. Tongue extends to the very end of the bill, and is sharp and horny at the point. Irides hazel; from the bill to the eye a dusky line: over the eye a white one: the top of the head, neck, back, and wings, ash colour; lower order of coverts tipped with white, and edged a little way up with the same, making a bar across the wing when extended; greater quills darker, with white shafts: lower part of the back and tail coverts dark ash colour, mixed with white, forming spots like crescents: tail ash coloured; the under part from the throat to the vent, white, with small dusky spots on the throat and breast; the sides under the wings, the belly, thighs, and vent, crossed with dusky lines; ridge of the wing white; the thighs feathered very nearly to the knee; the legs are short, in some bluish ash colour, in others reddish yellow; the toes are divided without any membrane. These birds, however, like others of the same genus, vary considerably from each other in their appearance at different seasons of the year, as well as from age and sex. Knots have been observed about Lake Baikal, and Mr. Pennant mentions a specimen which came from New York.

## L

LADY'S PAD. See HACK.

LAIR. The place where deer harbour.

LAMPAS. A disease very frequent in young horses. In this complaint the bars of the mouth project below the surface of the upper teeth, from which, however, the animal seldom sustains much inconvenience.

LAMPREY. The Lamprey is a sea fish, but, like the salmon, the latter end of winter, or early in the spring, ascends into the fresh waters, and after a stay of a few months, returns again (with the exception of a very few) to the ocean. It is reckoned a great delicacy, either when potted or stewed, but is said to occasion surfeits; a fatal instance of this occurred to Henry I. Notwithstanding this accident, this fish continued in high esteem, for Henry IV. granted protections to such ships as brought over lampreys for the table of his royal consort. It has been an old custom for the city of Gloucester to present his majesty annually with a lamprey pie, covered with a large raised crust. As the gift is made at Christmas, it is by great exertions the corporation can procure any fresh lampreys at that time, though they give a guinea a-piece for them. They are in best season in

March, April, and May, being firmer at their first coming from the salt water, and are observed to waste much, and to become very flabby at the approach of hot weather. It is also said that the string within them, which performs the office of a backbone, grows hard in summer, and they then lose their flavour. There is a much smaller kind of lamprey, which is potted, and made also into pies. This is the *petromyzon fluviatilis* of Linnæus: it is a small fish, and it was formerly, whatever it may be at present, of great and national importance.

LAND RAIL. See DAKER HEN.

LAPWING. See PLOVER.

LAWS OF THE LEASH OR COURSE-ING. First, it was ordered, that he who was chosen fewerer, or letter-loose of the greyhounds, should receive the greyhounds matched to run together into his leash, as soon as he came into the field, and follow next to the hare-finder till he came unto the form; and no horseman or footman, on pain of disgrace, to be before him, or on any side, but directly behind, the space of forty yards, or thereabouts.

2. That not above one brace of greyhounds do course a hare at one instant.

3. That the hare-finder shall give the hare three sohos before he put her from her seat, to make the greyhounds gaze, and attend her rising.

4. That the fewterer shall give twelve-yards law ere he loose the greyhounds, except it be in danger of losing sight.

5. That dog that giveth the first turn, if after the turn be given, there be neither coat, slip, nor wrench, extraordinary; I say, he which gave the first turn shall be held to win the wager.

6. If one dog give the first turn, and the other bear the hare, then he which bore the hare shall win.

7. If one give both the first and last turn, and no other advantage between them, the odd turn shall win the wager.

8. That a coat\* shall be more than two turns, and a go-by, or the bearing of the hare, equal with two turns.

9. If neither dog turn the hare, then he which leadeth last at the covert, shall be held to win the wager.

10. If one dog turn the hare, serve himself, and turn her again, those two turns shall be as much as a coat.

11. If all the course be equal, then he which bears the hare shall win only; and if she be not borne, the course shall be adjudged dead.

12. If he which comes first in to the death of the hare, takes her up, and saves her from breaking, cherishing the dogs, and cleanseth their mouths from the wool, or other filth of the hare, for such courtesy done, he shall in right challenge the hare: but not doing it, he shall have no right, privilege, or title therein.

13. If any dog shall take a fall in the course, and yet perform his part, he shall challenge the advantage of a turn more than he giveth.

14. If one dog turn the hare, serve himself, and give divers coats, yet in the end stand still in the field, the other dog, without turn giving, running home to the covert; that dog which stood still in the field shall be adjudged to lose the wager.

15. If any man should ride over a dog, and overthrow him in his course, (though the dog were the worse dog in opinion, yet) the party for the offence shall either receive the disgrace of the field, or pay the wager: for between the parties it shall be adjudged no course.

16. Lastly, those who are chosen judges of the leash, shall give their judgments

presently before they depart from the field, or else he in whose default it lieth, shall pay the wager by a general voice and sentence.

Such are the original Laws of the Leash or Coursing; which have, we believe, of late years experienced some local alterations.

**LAWS RELATING TO FISH.** By the statute 3 Ed. I. c. 1. none without license shall fish in another's vivary, (a place where fish are kept, 2 Inst. 162,) on pain of imprisonment, ransom, and double damages to the party, if he will sue; if not, the king shall have the suit as against the peace; and persons indicted shall be attached and distrained to appear within a month; then a second *distringas* to appear in six weeks; and, on default, shall be convicted and fined. And misfeasors in fish-ponds shall make amends, &c. c. 20.

By the stat. 13 Ed. I. c. 47. and 13 Rich. II. 19. none shall take salmon between 8th September and 11th November; nor young salmon with engines at mill-pools, between the middle of April and 24th June; nor with nets or engines destroy the fry of fish, on pain of having the nets burned for the first offence, of imprisonment for a quarter of a year for the second, and of a whole year for the third.

By the stat. 17 Rich. II. c. 9. justices of the peace shall be conservators of the above statutes, and may appoint under conservators, and at sessions enquire of defaulters, &c.

By the stat. 1 Eliz. 17. none shall take the young fry or spawn of fish; nor kill pike under ten, salmon under sixteen, trout under eight, or barbel under twelve inches; nor fish, unless for smelts, loaches, minnows, gudgeons, or eels, but with an angle, or a net of a mesh of two inches and a half, on pain of 20l. of which justices of peace may enquire, if no presentment in the leet within a year.

By 22 and 23 Chas. II. c. 25. a person convicted by confession of one witness, within a month after the offence, before any justice of the peace, of taking fish in a river, pond, &c. or assisting thereto, without consent of the lord, or the owner, shall pay to the party not exceeding treble damage, and to the poor not exceeding ten shillings, what the justice thinks meet, to be levied by distress and sale, &c. and in default to be committed, not exceeding a month, unless he give bond, with surety, not above ten pounds, not to offend more.

\* A coat is when a dog completely passes his fellow, and gives a turn.

By the stat. 4 and 5 Will. and Mar. 23. none shall keep any net, &c. for taking fish, other than the owner or occupier of a river or fishery : and the owner or occupier of a river or fishery, or any authorised by them, may seize them from persons using the same without consent.

By statute 5 Geo. III. c. 14. persons stealing fish from any river or pond, in a park or paddock, fenced in and inclosed; or from a garden, orchard, or yard adjoining or belonging to a dwelling house, or aiding or receiving, to be transported for seven years, on conviction, at goal-delivery.

For stealing fish in other inclosed ground, private property, forfeiture 5l. to the owner, or commitment for six months by one justice.

By the *black act* (9 Geo. I. c. 22.) it is made felony, under some special circumstances, to steal in a fish-pond. If any person shall unlawfully and maliciously break down the head or mound of any fish-pond, whereby the fish shall be lost or destroyed, or shall rescue any person in custody for such offence, or procure any other to join him therein, he shall be guilty of felony, without benefit of clergy.

*Conviction.* A conviction on this act (5 Geo. II. c. 14.) must shew that the fishing, &c. was without consent of the owner; and it must appear upon oath who was the owner. 4 Burr. 2279.

If a man is convicted of taking fish, without saying of another person, or in another person's pond, or without the consent of the owner, (or stealing Qu.) it is bad. Rex. v. Mallison, M. 32 G. II. 2 Burr. 679.

LEAM or LIAM. A line to hold dogs in, otherwise called a Leash.

LEAPING:—more fashionably termed JUMPING, is a very leading quality in a horse as a hunter. Leaping, in its general signification, extends to the two kinds, called flying and standing; a horse perfect in each, with good temper, and a fair portion of speed, is a complete or made hunter; and if he has a corresponding uniformity of figure, and excellence of action, both his reputation and worth become increased in proportion. There are very few horses of speed and spirit, but what become good flying leapers by a little practise in the field with hounds, which, indeed, is the only proper place to teach them; but it is not so with standing leaps, which should be taught coolly and calmly at the leaping-bar, and also in the field.

LEASH. A term used to imply the number three, as exceeding one, and not reaching two, brace; for instance, a brace of hares, a leash of pheasants, and two brace of partridges. Also, a leather thong or cord by which a falconer holds his hawk, or a courser his greyhound.

LEGS. The legs of a horse are so material to graceful and expeditious action, that they become, at the time of purchase, objects of minute inspection: if too long, in proportion to the depth of the chest, and the length of the carcase, they may be considered a tolerable criterion of constitutional weakness, as few of this description are found equal to a constant repetition of even moderate work. Too straight in the lower part of the leg, with the hoof overhung by the fetlock, is an indication of stiffness and constraint in action; as, on the contrary, those who are exceedingly long in the lower joints, and whose pasterns extend the hoof considerably before the leg, with a palpable bend or flexibility in walking, and the heel nearly down to the ground, are mostly horses of speed, (so far as their strength will permit;) but they are in general weak in those parts, and there is always a well-founded fear of their breaking down.

LEGS, SWELLED, originate in various causes; but from none so much as a sizzly, viscid state of the blood, a laxity of the solids, a shameful neglect of stable discipline, or a great deal of work at one time, and no regular exercise at another. That swelled legs arise from different causes, is sufficiently demonstrated by the opposite state of their external appearance in the examination of different subjects; where the legs of one shall be found distended to the utmost possible extent of the skin, with a degree of tenseness from the knee or hock downwards, not submitting to pressure, and without the least cutaneous pliability whatever. These are the kind of swelled legs occasioned by stagnant fluids, originating in the sizzly and viscid state of the blood. When they are equally distended, but pliable in the skin, yielding to pressure, and resuming their previous extension, it may be justly concluded, they proceed from a laxity of the solids, and a want of regular exercise without, and manual labour (leg rubbing) within. Proceeding from whichever cause, they are productive of temporary anxiety; and the cause should be removed without delay. Bleeding, with evacuants, and a course of alteratives, will expeditiously

EXTRAORDINARY LEAP TAKEN BY COL. STANDEN

eradicate the former; cordial invigorants, malt mashies, moderate exercise out, and regular bodily friction and leg-rubbing within, will soon obliterate the latter.

LENGTHS, &c. OF THE PRINCIPAL RACE COURSES.

*Ascot Heath.* A circular course, exactly two miles, the last mile of which forms the Old Mile. The New Mile is straight, rising all the way, and measures 7 fur. 150 yds. The T. Y. C. (part of the New Mile) is 3 fur. 95 yds. The ground remarkably well kept, the races are graced by Royalty, and splendidly attended.

*Buxton.* A circular course of one mile.

*Chelmsford.* An oval course, 30 yards short of two miles; but, by starting between the distance post and the winning chair, it becomes two complete miles.

*Chester.* A circular course of one mile. It is a complete flat, and perhaps the pleasantest course in England for spectators; where also the races are well conducted, and brilliantly attended.

*Doncaster.* A circular course of 1 mile, 7 fur. 70 yds. The other courses are formed of portions of this circle, namely, Red House-in, 5 fur. 164 yds. T. Y. C. 7 fur. 189 yds. Fitzwilliam Course, 1 mile, 4 fur. 10 yds. St. Leger Course, 1 mile, 6 fur. 132 yds. Two Mile Course, 2 miles, 25 yds. Four Mile Course, (twice round) 3 miles, 7 fur. 219 yds.

*Egham.* A flat oval course, 66 yds short of 2 miles.

*Epsom.* Two miles, the last mile and a half of which, is the Derby and Oaks Course. The Craven Course is one mile and a quarter of the same ground. Epsom Course can be properly called neither circular, oval, nor triangular.—It is altogether one of the worst courses in England. The ground better kept than formerly.

*Knutsford.* A flat circular course of one mile; and certainly not of the best description.

*Lancaster.* A circular mile course, and good turf.

*Leeds.* A circular course of 1 mile, 2 fur. 48 yds. There is also a straight course through the centre of the circular one, of 2 fur. 158 yds. which, uniting with each half of the circle, forms two other courses, in the form of a sector; the one, 1 mile, 11 yds, the other, 1 mile, 135 yds.

*Liverpool.* The Old Course is an oval

mile, flat, and very good turf. The New Course is one mile and a half, forming an ill-defined oblong square; and though nearly flat, is a very distressing course for horses. It is a new establishment, races being held upon it this year (1829) for the first time. The course is situated upon what may be called a kind of semi-morass, the whole length of it laid with turf cut expressly for the purpose, which gives it a fine appearance. I am at a loss to account for the distressing nature of this course, unless it arise from the heterogeneous or adverse nature of the strata upon which the turf has been placed, and which may perhaps thus cause a sort of undulatory sinking, imperceptible to the eye, but which may, nevertheless, be severely felt by the horses.—Further, though the course presents a good appearance, yet the horses are by no means seen to advantage. In this respect it is worse than Epsom, though in quite a different manner. The form is bad—it is too elongated, and, in consequence, causes the horses, for a great part of the length, to be too far distant. The Old and the New Course are situated at the distance of two miles asunder.

*Manchester.* An oval course of 7 fur. 184 yds. The Cup Course is 2 miles, 168 yds. The T. Y. C. 5 fur. 184 yds. There is a hill, and the course is by no means of the best description: it is badly kept, and the races, on the whole, not well conducted.

*Newcastle.* A sort of square of 1 mile, 6 fur. 132 yds.

*Newton.* A triangular course of one mile; containing a sudden strong hill, and is altogether an indifferent course, though formed upon fine elastic turf, and susceptible of great improvement.

*Nottingham.* A circular course of 1 mile, 2 fur. 11 yds.

*Oxford.* Flat, oval course, two miles all but a distance.

*Pontefract.* An oval course, formed on the gentle declivity of rising ground, 2 miles, 1 fur.

*Preston.* An indifferent oval course, one mile; the ground badly kept; the practical management slovenly.

*Stockbridge.* An oval course, rather hilly, the last three quarters of a mile in a straight line. There is one straight mile, and also a circular course of about one mile and a quarter; the latter is called the New Course.

*York.* T. Y. C. 5 fur. 59 yds. Mile Course, 1 mile, 8 yds. Last mile and a

quarter, 1 mile, 2 fur. 15 yds. Last mile and half, 1 mile, 4 fur. 18 yds. Last mile and three quarters, 1 mile, 5 fur. 160 yds. Two-mile Course, 1 mile, 7 fur. 85 yds. Four-mile Course, 3 miles, 7 fur. 24 yds. York Course is situated upon low ground, and, in consequence, becomes very heavy in wet weather.

*Newmarket Courses.*

N. B. 1760 yards are a mile. 220 yards are a furlong. 240 yards are a distance.

LESSES. The dung of a wild boar, bear, or wolf.

LETHARGY. " Sometimes ( says Gibson) horses are seized with sleepiness in very great colds, especially those colds that have some degree of malignity in them ; but this symptom generally wears off as the distemper abates. But a true lethargy seldom happens unless to horses that are old, or growing old, and to such especially that have been worked beyond their strength and keeping. I have known many horses seized with lethargic disorders after very hard labour, when there has not been sufficient time allowed for food and rest, by which nature has received such a shock, that some have died, notwithstanding proper applications have been made to recover them. Others have recovered with much difficulty ; and, of those, some were not afterwards able to go through any fatigue.

When a horse falls into a lethargy, he generally rests his head with his mouth in the manger, and his poll often reclined to one side, which denotes great stupor and insensibility. As there is seldom any great pain, he will shew an inclination to eat, but is apt to fall asleep with the hay, bran, oats, or whatever else has been given him, in his mouth. These, indeed, he seldom chews, but swallows them down. Except he is roused, and his head kept moving, he presently drops asleep again ; and, if a horse continues any time in this state, he falls into an atrophy, or universal decay, especially if his lungs, liver, or any other of the principal viscera be diseased, or if he has received any hurt on his head.

A lethargy in a horse may be cured, if he is not very old and past his vigour. It is always a good sign if he has a tolerable appetite, and so far retains his smell and taste as to eat up a mash with a relish, and without dozing over it ; for, though he eat but little hay, if, at the same time, he drinks pretty freely, without slabbering, and lies down and rises up carefully, even though it be but seldom, some hopes may be entertained of his recovery. But if a lethargic horse does not lie down ; if he is altogether stupid and careless, and takes no notice of any thing that comes near him ; if he dungs and stales seldom, and even when he sleeps and dozes ; his situation is bad. If he runs at the nose a thick white matter, it may relieve him ; but if the discharge be a viscid gleet that sticks to his nostrils like glue, and if this becomes profuse, and changes to a ropy, reddish, or greenish matter, with an increase of the symptoms of stupor, it is an infallible sign that (as the name of this distemper imports) it will prove deadly.

As to the cure, if the horse be young, and this distemper arose either from catching cold in some damp place, or from any hard usage, there may be great hopes of his recovery, because the disease, in this case, is in some measure symptomatic. The right way is to begin with bleeding, but not in too great quantity ; for lethargic horses are seldom able to bear the loss of blood, unless they be young and lusty. After bleeding, give the following drink, which consists both of pectoral and cephalic remedies ; for, in some lethargic disorders, the lungs are also much affected.

Take of the leaves of Pennyroyal,  
Coltsfoot,

## L E V

Chamomile flowers, of each a handful;

Rue,

Hyssop, of each half a handful;

Liquorice root sliced, an ounce.

Infuse these in two quarts of boiling water, in a deep vessel, close covered; and, when it has stood to be cold, pour it off.

Also,

Take of Assa foetida,

Russian castor, of each half an ounce;

Saffron, one drachm.

Bruise the assa foetida and castor, and shred the saffron; then tie them in a rag, and let them steep all night in a pint of strong mountain wine, or in the same quantity of spirits of wine and water, about three parts water to one of the spirits.

In the morning give a pint of the first infusion, with a quarter of a pint of this tincture; the same quantity in the afternoon, and also on the days following, squeezing the rag with the castor and assa foetida in each dose, leaving it always to soak in the tincture till there is occasion to use it again, and that no taste or colour remains in it. The first three or four days let the horse have emollient clysters; for, in all these distempers, they are apt to be costive. These are best made of fat broth, or of the leaves of mallows and marsh-mallows, boiled in water or milk, with an ounce of sweet fennel-seed, adding half a pint of linseed oil, and the same quantity of common treacle, to three pints or two quarts of the decoction.

If the sleepiness wears off, and the horse begins to move with spirit and vigour, give him one of the following balls every morning fasting, for a fortnight or three weeks:

Take of Cinnabar of antimony,

Assa foetida, of each half an ounce;

Castor, in powder, two drachms.

Beat this mass into a ball with a sufficient quantity of oil of amber.

After the use of these, should the horse come to feed heartily, two or three mild purges may be proper, just such as will thoroughly open his body."

LEVANTER is a word very well understood on the turf, and means a person who does not pay his bets; but this is an evil which works its own cure, as Levanters soon become known, and consequently despised: they are not allowed to mix in

## L O A

the betting stand or circle, and are shunned by all honourable men.

LEVERET. A young hare is termed a leveret till she is full grown.

LICE IN DOGS, TO DESTROY. See DISEASES OF DOGS, under the general head of DOGS.

LIFTING HOUNDS. Hounds are said to be *lifted* when they are taken by the huntsman from one point to another. For instance, if they have much difficulty in carrying the scent, or are a great way behind the fox, if the fox should be hallooed or seen at any particular spot, the hounds are immediately taken the nearest way to that spot, and there laid on the scent. This is termed *lifting*; but for a complete exemplification of the subject we refer the reader to Fox HUNTING.

LIGHT IN HAND. A horse is said to be light in hand, who, bearing properly upon his haunches, requires little or no assistance from the bit. Horses of this description are generally well formed in their fore-quarters, with a curved crest, carrying their heads well up, with long necks, high withers, and a commanding forehead. Those with short necks, thick shoulders, dull spirit, slow action, and the withers lower before than the spinal bone behind, are always of a contrary description; they bore along, invariably bearing upon the bit, and from that circumstance are said to be heavy in hand.

LIGHT CARCISED. The carcasses of such are flat at the sides, narrow in the chest, and gradually contract in circumference from the girth to the flank. Horses of this description possess, in general, a spirit so much beyond their strength, that they debilitate themselves so much by impetuosity, and unnecessary exertion, that, after a single day's hard work upon the road, or a severe chase in the field, they are not fit to be brought into use for a week after. They are always bad feeders; and it is an old maxim with the sporting world, "that those who won't eat can't work;" and this remark is literally just; they certainly cannot for any length of time together.

LIME TWIGS. Preparations of bird lime, with which almost all kinds of birds may be taken.

LOACH. This little fish is found in swift brooks among the gravel, or where there is a soil of mud and gravel together, with weeds, and in several of our rivers by the sides of sharp streams; it seldom rises to the top of the water, keeping at the bottom on the gravel, upon which it

feeds, and is on that account in some places called the groundling : it is frequent in the streams near Amesbury, in Wiltshire, where out of frolic the sportsmen swallow it down alive in a glass of white wine.

It is a slimy fish without scales perceptible to the naked eye, and of rather a long make ; the mouth is small, placed beneath, and has no teeth ; it is bearded like the gudgeon and the barbel, having on the upper mandible six small beards, one at each corner of the mouth, and four at the end of the nose ; the body is smooth and slippery, and almost of the same thickness ; the colour of the head, back, and sides, is in some white, in others of a dirty yellow, very elegantly marked with large spots, consisting of numberless minute black specks : the pectoral, dorsal, and caudal fins are also spotted ; the belly and ventral fins of a pure white ; the tail, where it joins to the tail fin, remarkably broad without any taperness ; the tail fin is broad and rather rounded. One of the largest ever heard of by Mr. Pennant, was four inches and three quarters in length, but they seldom exceed three inches. The flesh of the loach is singularly nutritious, and from that circumstance, and its being equally grateful to the palate, it is recommended to the sick. The females during summer are generally full of spawn. These fish are to be taken with a very small red-worm, the bait touching the ground. The loach is used as a bait for other fish, and for eels perhaps it is the best.

**LOCKED JAW.** A tetanic or spasmodic disease, to which horses of all ages are liable. It is more frequent in hot than in cold climates, and the symptoms of it are there more severe. The most common causes of locked jaw are, punctures of different tendinous parts, attended with some injury of the nerves supplying those parts, and producing an universal irritation of the nervous system, accompanied with a greater or less degree of spasm in the whole of the muscular powers. The operations of nicking and docking also occasion it, more particularly the latter, and these especially in frosty or other severe weather. Other causes are, cold applied to the body when hot ; journeys in bad weather, after having been indulged a long time with a hot stable and clothing. Horses pricked in shoeing are also liable to locked jaw. From the sympathy known to exist between the stomach and the brain, botts and other

worms have been supposed, sometimes to give birth to this disease, by adhering to and wounding the nervous coat of that organ. But locked jaw will frequently occur independently of any apparent reason. It sometimes proceeds to a violent degree very suddenly ; in other instances very gradually only. Previously to an absolute state of locked jaw, some rigidity is to be perceived in the muscles of the neck : as this proceeds, the extremities begin to undergo a similar effect ; the legs become stiff, and are drawn much apart : the ears and tail are erected, the nostrils expanded, and the eyes fixed, displaying, in appearance, an unusual and considerable fire and animation. Much difficulty seems to be experienced in deglutition, the abdominal muscles are strongly affected with spasm, and the body is drawn or *tucked up*. The bowels are generally obstinately costive, and the respiration is usually more or less influenced by the disease. In all spasmodic affections of the muscles, acute pain is experienced, causing an irregular state of the pulse. There is a deficiency in the secretion of the urine in this disease, but no diminution seems to take place in the appetite.

There are but few veterinary practitioners, probably, who can boast of having been very successful in the treatment of locked jaw. Though they may be well acquainted with its most prevailing symptoms, the method of cure yet remains an object highly worthy of the exertions of laudable enquiry. Perhaps some future period may give to the world a certain remedy for this dreadful malady ; and such an event would be not less desirable to human than to veterinary medicine.

For the cure of locked jaw, the greatest extremes of heat and cold have been recommended ; such as supporting a high state of perspiration in the animal for several hours, by covering the body in blankets, &c. or immersing the patient for a length of time in snow or cold water. We have heard of advantages attending both these methods, and we have had a few opportunities of giving each of them a fair trial ; not, however, with that benefit that we could have wished. It will be here necessary, notwithstanding, to point out the most probable means of success. We are convinced, that, in cases of locked jaw, opium, in large doses, is the remedy on which our hopes are principally to be founded : it may be given, indeed, in very large quantities in

all spasmodic diseases, without being attended with those hurtful consequences it is commonly accompanied with on other occasions. The doses ought to be repeated as the power of them appears to wear off. In the infancy of the disease, where the pulse will justify it, by indicating an inflammatory propensity, bleeding is required; but, without this precaution, the practice is now generally considered as improper. A costive state of the intestines will certainly tend to aggravate the complaint; so that, by relaxing them, we may probably promote a relaxation in other parts. Therefore, when we are not prevented by the closeness of the jaws, or the difficulty of deglutition, and when costiveness exists, the following drench may be given every six hours, until it operates.

Take of Thin gruel of oatmeal, one pint;

Castor oil, or

Olive oil, twelve ounces;

Glauber's salt, four ounces.

Dissolve the salts in the gruel, whilst warm, and afterwards mix the whole into a drench.

Spasmodic diseases are such as allow the loss of but little time; of course, before we can possibly perceive the consequence of this aperient treatment, it behoves us to employ, in the mean while, other useful medicines.

Let the following ball be given every three or four hours, or as often as the state of the case may demand.

Take of Purified opium, three drachms;

Salt of hartshorn,

Camphor, of each half an oz.

Syrup, sufficient to make a ball.

We have already remarked, that costiveness is to be avoided as much as possible: laxatives, independent of other utility in the above complaint, will beneficially counteract the astringent quality of opium. So far we have been treating of the disease as in its most favourable stage. When the jaws are already so far closed as to prevent the admission of medicines, the only means left are introduction of them in clysters. Of these, a laxative one, as the following, may be given, at the discretion of the practitioner.

Take of Thin gruel, four quarts;

Common salt, six ounces;

Olive oil, or

Hog's lard, four ounces.

Dissolve them together, and administer in the usual manner.

We cannot precisely ascertain the quantity of the opiate that can be administered in this way to the horse with safety: we conceive, however, that it is pretty considerable. The following may be injected without danger every three or four hours.

Take of Oatmeal gruel, one quart;

Purified opium, six drachms;

Spirit of hartshorn, one ounce and a half;

Camphor (previously rubbed into a liniment with a little spirit of wine), one ounce.

Dissolve the opium first in the gruel, and mix the whole well together.

It is necessary to remark, that this composition can prove but of little utility during the active operation of the laxative clyster; and, of course, it should be contrived that these very opposite remedies interfere as little as possible with each other.

Notwithstanding, we have not yet been lucky enough to witness the success of the application of cold water to the surface of the bodies of horses labouring under locked jaw, our hopes of its beneficial tendency are still sanguine; and we are induced to think the more favourably of it from the encouraging reports communicated to us by others. In similar diseases of the human subject, its use has been attended with the most beneficial consequences. Immersion in cold water is readily accomplished; but, perhaps, the most efficacious method would be that of pouring large streams of water on the animal. This process should be continued for a considerable time, perhaps ten or fifteen minutes; and, should a remission of the spasms ensue, it will afford us no little encouragement in our pursuit; and, in this interval of ease, a favourable opportunity will present itself of passing medicine by the gullet. When the complaint returns with any degree of violence, the cold water is to be repeated: the longer and the more frequent the remissions become, the nearer, of course, will be the prospect of cure. Immediately after the application of the cold water, let the skin undergo a diligent and general friction until it is dry; let the animal be then moderately clothed. We have already hinted, that horses, suffering from the above disease, have generally the inclination, though perhaps they have not the power, to eat: they are, therefore, to be supported with substantial gruel, given, when incapable of swallowing, by the anus. If this circumstance is suffi-

ciently attended to, the animal may be kept alive many days.

Here, however, a question occurs to us—Whether, in any case of locked jaw, either in the human or brute species, the throat is *absolutely inaccessible to nutritious fluids*? We think not; but that milk, gruel, broths, and even porridge, might be conveyed by injection between the intervals of the teeth, and drawn in, in some quantity, by the patient, provided the power of swallowing remain.

We have here endeavoured to describe such means of relief as have appeared to us to offer the greatest prospect of success. All rational experiments towards the removal of a malady, usually fatal in its termination, are certainly praise-worthy; and he who is the most fortunate in his researches will have a weighty claim indeed on the gratitude of society.

The introduction of mercury into the system, in persons affected with the spasmodic diseases, by frictions, on different parts of the body, with strong ointment of quicksilver, so as to produce and support a degree of salivation, has been sometimes attended with the happiest effects. We have never heard of this experiment being tried on the horse, but certainly it deserves the practitioner's attention.

The warm bath, in spasmodic diseases, has many advocates: perhaps it might be beneficial, if it could be used to that extent with the horse which it admits of with the human subject. When locked jaw is conjectured to have arisen from the operation of docking, it is usually considered prudent to remove another portion of the tail; afterwards applying such dressings as are most likely to hasten a free discharge of matter from the stump. The same dressings may be recommended when nicking is suspected to be the cause of the disease, and the extremity may be also surrounded with a large poultice. Few owners of horses, we fancy, would allow of a total amputation of the tail, and, probably, even that would not be followed by the slightest benefit. Where the disease arises from the foot having been pricked in shoeing, the wound should be opened freely to the bottom with a drawing knife; the actual cautery may then be applied, and the part scalded with a little turpentine as a dressing. All punctures should be laid tolerably open, and digestive applied; and, where an inflammation and swelling attend, fomentations are requisite. Let it be remembered, however, that these topical means

*alone* are never to be depended upon; but must, in locked jaw, be invariably assisted with the remedies heretofore mentioned. Should it be imagined that botts, or other worms, lodged in the stomach or intestines, have produced the disease (a circumstance which we are apprehensive is rather difficult to determine), a drachm of calomel may be given in one of the balls, or an ounce of the strong mercurial ointment may be dissolved in the first anodyne clyster.

In conclusion, we may observe, that we have witnessed the recovery of a few mild cases of locked jaw, in which scarcely any means of relief have been employed, except turning the horse into the cold air: indeed, such cases so frequently terminate fatally, that the owners of horses thus diseased generally leave them to their fate. In the above instances, considerable rigidity existed in the muscles; the act of deglutition was slightly obstructed, but not prevented; and the jaws were only partially drawn together. On these occasions, the complaint could seldom be traced to any particular source.

**LOOSE-JOINTED.** A horse is said to be loose-jointed, when his pasterns are so long as to let his hoof come considerably from under the perpendicular position of the fore leg, so that the heel is exceedingly flat, and the hinder part of the fetlock joint, by a kind of elastic bend or drop, seems nearly to touch the ground. Horses of the blood kind have frequently this failure in their formation: most of this description have the first defect accompanied by a second, which is a long back, and consequent weakness of the loins: these, in the aggregate, constitute a complete loose-jointed horse.

**LOUSINESS.** It is a very common case to see horses, oxen, cows, and other animals, affected with lice, or other animalculæ, particularly those which have been fed upon barren pastures, or kept in a state of starvation, &c.; because, such keep diminishes the vital heat, and reduces the strength of the body. As a proof of this, it will be observed, that lice are never seen amongst horses, or any other animals, which are duly fed, and judiciously taken care of. Poverty produces many diseases of the skin in horses and other animals, such as lice, the mange, farcy, &c. However, this disorder is extremely easy to cure in brute animals, since it requires nothing more than to pay attention to good and judicious feed-

ing, and cleanliness. And when this is thought, or found, ineffectual, corrosive sublimate, (*hydrargyrus muriatus*) dissolved in a strong infusion of tobacco, in the proportion of a drachm, to two quarts of the infusion. Or, cantharides, half an ounce; hellebore, two ounces; infuse the whole in two quarts of tobacco water.

**LOWBELL.** The use of this instrument is not likely to be conducive to the amusements of the sportsman of the present day; but as it was formerly used by sportsmen, and afterwards was employed by poachers; and as it is occasionally noticed in some of the statutes relative to the preservation of game, a few words upon the subject may be interesting, if not useful. The lowbell and the hand net were used in conjunction. "With these instruments (says a writer) birds are taken in champaign countries, as also in stubble fields, especially that of wheat, from the middle of October to the end of February, and after this manner:—When the air is mild, about nine o'clock at night, the moon not shining, take the lowbell, which should be of a deep hollow sound, and of such reasonable size as may be well carried in one hand; toll this bell just as a weather sheep does, while he is feeding in pasture ground: you must also have a box much like a lanthorn, about a foot and a half square, big enough to hold two or three great lights; let it be lined with tin, and one side open to send forth the light; fix this box to your breast to carry before you, and the light will cast, at a great distance before you, very broad, by which means you may see any thing on the ground within the compass of the light, and consequently the birds that roost therein.

For the taking of them, you are to have two men with you, one on each side, walking a little after you, that they may not be within the reflection of the light that the lanthorn or box casts forth; and each of them should be provided with a hand net, about three or four feet square, which must be fixed to a long stick, to carry in their hands, so that when either of them sees any birds on his side, he is to cast his net over them and take them up, with as little noise as may be; and let him that carries the light and lowbell be the foremost to take them up, without being too hasty for fear of raising others.

The sound of the lowbell causes the birds to lie close, and not to stir while you lay the net over them.

If you would practise this sport by yourself, carry the lowbell in one hand, and in the other a net, about two feet broad and three long, with a handle, which is to lay upon them as you espy them. But some persons, instead of holding the light to their breasts, tie the lowbell to their girdle, and their motion causes the bell to strike; and the light they carry in their hand, extending their arm before them; but then their lanthorn or box is not so large as that hung at the breast."

**LUNGS** consist of two lobes that fill up the greatest part of the chest, having the mediastinum between them. In some quadrupeds each lobe is subdivided into several small lobules, in the same manner as their livers, but not so much in a horse as in other animals that have a greater variety of motions. Gibson supposes this may be the reason why horses' lungs are so apt to be inflamed with hard exercise, and in consequence of cold. The *aspera arteria*, trachea, or wind-pipe, descending along the fore part of the throat, is branched out into the lungs. This pipe is composed of circular rings of cartilage or gristle, which surround it for about two thirds of its circumference; the back part being plain, smooth, and even, that it may not incommodate the *œsophagus* or gullet, which passes down immediately behind it, and which it ties. At its entrance into the chest, it is divided into two principal branches, called its *bronchia*; and is afterwards subdivided into innumerable other branches, the extremities of which compose an infinite number of small cells or air-bladders, which, with the ramifications of the veins, arteries, nerves, and lymphatics, make up the whole mass or substance of the lungs. These cells or vesicles are always filled with air, and distended in inspiration, and empty or sunk in expiration; and receive from the blood-vessels a quantity of lymph, or perspirable matter, which not only keeps the lungs from drying, but makes a large and necessary discharge from the blood. The lungs may justly be reckoned among the principal organs of the body, if not the chief of all; as they are adapted in every respect to receive air, without which, we cannot support life one moment; and are no less fitted to communicate oxygene to the blood by their continual action, and also to make such discharges of aqueous vapour and mucus as are necessary for the continuance of life. The

lungs are also the chief instruments of the voice in all creatures ; and, by drawing the effluvia through the nose, contribute greatly to the sense of smelling.

**LURCHER.** The dog passing under this denomination is fast fading from the face of nature ; and in all probability will, at no distant period, be utterly extinct. The breed, it is true, might easily be revived were it totally extirpated ; but as they are considered disgraceful to the sportsman, and cannot fail to attach suspicion to the lower orders, little doubt can be entertained that they will shortly disappear altogether.—The lurcher is said to have been originally produced from a cross between the greyhound and the shepherd's dog, and its appearance would certainly justify such a conjecture. Those who have seen the rough or wiry-haired greyhound, so common in many parts of the north of England, will have a tolerably correct idea of the figure of the lurcher, by imaging to the mind an animal similar in form, but only about two-thirds or three-fourths the size ; in fact, the lurcher may be regarded as a smaller kind of greyhound. This dog has not, as some have hastily supposed, a good nose, or, in other words, exquisite sense of smell ; on the contrary, like all narrow headed individuals of the dog tribe, it is deficient in the faculty just mentioned ; and as if perfectly conscious of the defect, it endeavours to make up by artifice and cunning, its evident want of olfactory nerves. The lurcher may be regarded as a most accomplished rabbit-catcher ; and for this purpose he adopts most extraordinary stratagems. He skulks round the borders of the warren ; and if he espies any rabbits, he does not run at them (unless they are at a considerable distance from their burrow), but hides himself from their view, and, by crouching and creeping along, endeavours to place himself between them and their hiding place, and thus cut off their retreat. The moment he has completed this preliminary manoeuvre, he shews himself, singles out his victim, and seldom fails to secure it. It will be necessary perhaps to remark, that the rabbit would be very likely to beat the lurcher in speed, were the race to the burrow distant not more than two hundred yards, and no intervening obstruction offered to its progress ; but the dog appears so well aware of this circumstance, that if there seems the least chance of his game thus escaping, he instantly ceases to follow the rabbit, and strains every nerve to throw himself between it and the hole, or at least to reach the hole before it. A rabbit seems to lose its courage and confidence, when it perceives its retreat intercepted, and is captured with little difficulty. The lurcher pursues the chase in silence, and carries the prize to his master : should he be met on the road by a stranger who attempts to rob him of the fruit of his labour, he will seldom relinquish it without a stout resistance, and till he has made the best defence his strength and courage will allow. The lurcher is very dextrous in taking young hares ; and though he is seldom equal to the capture of old ones, yet leverets, about three parts grown, rarely escape him : in this pursuit, as well as that of the rabbit, he resorts to every imaginable stratagem.

For the purposes of the poacher the animal in question is admirably calculated. In nocturnal expeditions, where hares are to be captured, the lurcher appears perfectly to understand the business upon which he is employed ; and will run hares in silence and with almost unerring certainty into the murderous engines prepared for their destruction. In fact, the lurcher is one of the most sagacious of the dog tribe ; and it is astonishing to what a degree of perfection some of these have attained by the instructions of an adept in the art of poaching ; but it is a mistaken notion, which some have adopted, in supposing that he is, like the spaniel, “crouching, humble, and obedient ;” on the contrary, though obedient to his master, he may nevertheless be considered as ill-tempered and snappish ; but it must be allowed that he imbibes instruction in a shorter space than would readily be believed, and soon conforms himself to the various motions, manners, and pursuits of the person who commands him.

**LURCHER.** The name of a horse of some recent celebrity ; he was the property of Mr. Rider ; was got by Dunganon, dam by Vertumnus. In 1792, when three years old, he won a 50l. plate at Ascot Heath, beating seven others. At Stockbridge, a subscription of 20gs. each, (ten subscribers) beating Hamlet, St. George, and two others. At Winchester, a sweepstakes of 20gs. each, eleven subscribers ; and at Lewes, a sweepstakes of 10gs. each, ten subscribers. He was then purchased by Mr. Wilson, in whose possession, 1793, when four years old, he won at Newmarket a sweepstakes of 500gs. each, from the Ditch-in, beating Kitt Carr and Ormond. On the Saturday in the same week, he won a sweepstakes

of 200gs. each, half forfeit ; beating Lord Clermont's Pipator. Lord Foley's Vermin paid. Second spring meeting, he beat Lord Clermont's Speculator a match across the Flat, 200gs. each. In 1794, at the Craven meeting, Newmarket, he won the first class of the Oatlands stakes of 50gs. each (twenty-one subscribers), half forfeit, beating thirteen others, with the odds of nine to one against him at starting. For the main of the Oatlands, first spring meeting, he beat Lord Grosvenor's Druid, 200gs. each, Ditch-in. Second spring meeting, he received 150gs. forfeit from the Duke of Bedford's Teucer ; after which he appeared no more upon the turf.

## M

**MADNESS IN DOGS.** See DISEASES OF DOGS.

**MADNESS OR FRENZY.** A term somewhat indefinitely applied to those accidents or diseases of brutes which produce an irregular action of the brain. In the human subject, madness usually denotes mental derangement ; and as, in brutes, any morbid action or irritation on the brain is known by actions inconsistent with their usual habits, or the law of self-preservation, this analogy has been assumed by the old writers on farriery. Gibson says, that “madness or frenzy in a horse may be caused first of all by the excessive hurry of the blood in a legitimate simple fever : but that symptom will very readily abate, by those things that are proper to assuage the violence of that disease. Secondly, blood or matter

collected upon the brain, or the membranes that involve it, may occasion a frenzy, whether that proceeds from wounds or bruises, or from a distraction or rupture of the vessels, when they have been over full and distended beyond measure ; or when there is any foreign substance grown within the skull : but then a frenzy arising from such causes will probably end in sudden death.

“But that sort of frenzy, which in a more peculiar manner deserves the name of madness, is what may happen without the concurrence of any other disease, and is most likely to proceed from excessive lust, occasioned by full feeding, either in a horse or mare, and when they are restrained from copulation. But this may be cured by bleeding, purging, with the concurrence of a low diet,” &c.

Bartlet says, "a frenzy may follow upon the bite of any venomous creature. The first intention in the cure, after the bite, and before the horse is mad, is to prevent the poison mixing with the blood. This possibly might be effected, if the part would admit of being instantly cut out with a knife, that cupping glasses might be applied, to empty the vessels, the wound being afterwards cauterized with a hot iron. The surrounding parts should afterwards be well bathed with salad-oil, and the sore dressed once or twice a-day with *mel ægyptiacum*. It is necessary also, that it should be kept open for forty days at least, with a piece of sponge or orrice-root smeared over with the precipitate ointment, or that prepared with Spanish flies : these seem to be the chief external remedies to be depended on. Internally, for bites from vipers, may be given cordial medicines, such as Venice treacle, and salt of hartshorn, an ounce of the former with a drachm of the latter, every night for a week ; or, where it can be afforded, a proportionate quantity of the famous Tonquin remedy of musk and cinnabar, so much recommended in bites from infected animals."

MAIN OF COCKS. See COCKING.

MALLENDERS. A large flat scab, or more properly an accumulation of eschars seated at the hinder part of the fore-legs, directly behind the knee, just where the back sinews have their insertion at that joint. They are seldom seen with horses that are properly managed, but merely with those of an inferior description, that are little attended to. If discovered, and proper means of counteraction adverted to in their early state, little or no inconvenience ensues ; but if suffered by time to become inveterate, with deep-seated cracks, from whence oozes a greasy kind of ichor, with bristly hairs making their way through the hardened scabs upon the surface, they are productive of much trouble before a perfect cure can be obtained.

Those horses having the greatest quantity of hair upon their legs are the most subject to this malady, where it remains a long time obscured from the eye. If the part inveterately affected is covered with hair, either totally or partially, it must be taken off as close as possible, before any attempt at cure is made ; that done, a patient fomentation of hot gruel, a decoction of linseed, or mallow roots and leaves, should be persevered in for a quarter of an hour daily, letting, however,

the process of soft soap and warm water be adopted on the first day, continuing one of the before-mentioned fomentations every day after. When the scabs or eschars are completely softened, got loose, and begin to exfoliate, the parts may be well impregnated with camphorated spermaceti liniment every day after the fomentation ; but not before the part is made properly dry to receive it.

MANEGE. Manege riding is the science whereby you become acquainted with, and learn, the superiority you have over the horse, by a proper correspondence of the hand—teaching the effect and power, every variation of situation and aids produce, with the theory and knowledge of dressing horses—improving your horse after what manner you please, rendering him obedient to the most delicate touches, riding him with the greatest ease and exactness, and making him display himself in the most elegant attitudes, and move either forward, backward, or sideways.

It is evident this style of riding is not suitable to those who want to trot at the rate of from twelve to sixteen miles an hour ; or gallop at the rate of twenty. No wonder, then, that it should be so little sought after, and the preference given to the common mode of riding.

Nevertheless, the study and knowledge of the manege has many advantages : for you are not confined to ride in the manege style when you find it most convenient to ride in any other : and certainly, if you ride fast, long distances, or a hunting, the manege style is not calculated for your own ease, or that of the horse. But whenever you adopt the proper style for these extended paces, and suffer the horse to take a support and ascendancy of the hand, you can, when you find it necessary, more readily recover the superiority of the hand than those who are totally ignorant of the science. Many of these you see pulling and labouring with all their might, to no effect ; and frequently exposed to imminent danger, from not being able to manage their horses ; and this they never attribute to their want of skill, but to the hardness of the horse's mouth.

Since, then, I allow the manege is not the style of riding for travelling, hunting, or racing, of what service can it be to the generality of persons whose pursuits tend that way ? I answer, much advantage is to be derived from it ; because the manege being the foundation and groundwork of all good riding, you will only adopt the

convenience of one, and reserve the excellence of the other, by which you acquire the greater security, and become the more perfect horseman.

We are often told the horse reared, and the person fell off behind, that the horse might not fall backwards on him ; but the occasion of the horse's rearing is not given : perhaps the severity of the rider's hand was the cause. But, admitting fright, or any other circumstance, might be the cause, the person seldom allows the impropriety of his riding ; which, under such circumstances, might increase his danger, or have occasioned the disaster.

Therefore, by a scientific knowledge of riding, you are guarded against the several contingencies that may unexpectedly happen, and are deterred from running into dangers which ignorance but too frequently incurs. You have likewise the advantage of improving such horses, that come into your hands, which are awkward from defective breaking, or bad riding ; and, I believe, most persons feel an extreme pleasure in the improvements they make ; as it is a confirmation of the goodness of their hand, and a proof of their abilities.

*On the Seat.* The seat is the conformation of the several parts of the horseman's body, agreeable to the position or manner the horse works in.

For instance, if a person was placed in what I shall call the fundamental seat or medium position (which will be first described), and the horse was to work in a bent position, or on a circle, the balance would be disturbed.

Likewise, if the horse passages, or works sideways, the balance would be endangered, or lost.

When a horse also plunges or kicks, if you have not a strong muscular hold with your legs and thighs, assisted by a corresponding motion or exertion of the body, you will be thrown from the saddle.

Thus the balance is maintained by as many different positions as the horse has capacity to work in ; and the violent exertions of the horse are repelled or counteracted by muscular strength and activity in the rider. Hence, a person may be an excellent horseman, though, for want of muscular strength and resolution, unfit to contend with obstinate, resolute, and vicious horses ; and a person of firm nerves and resolution, in the habit of riding, may contend with a vicious horse, and, where resolution only is wanting, will succeed ; but where skill and address

are required, most likely he will fail : success, in these cases, inducing many to imagine themselves very capital horsemen.

The fundamental seat is that medium position from which all others proceed, and in which the rider sits when the horse works straight, *i. e.* not only going straight forward, but without any bend in the position of the horse.

In describing this, I shall divide the horseman into three parts, and explain their different functions.

The first are the thighs, from the fork to the knees. These, at all times, have hold of the saddle, and, by their muscular exertions, contribute also to keep the body equipoised.

The second are the legs, from the knee downwards. These are auxiliaries, and, occasionally, strengthen the hold of the thighs by a grasp with the calves. They likewise request, aid, support, and chastise the horse.

The third is the body, from the fork upwards, which must always be in a situation to preserve the balance, and take the corresponding motion.

The thighs, to have an effective hold of the saddle, must be turned inward from the hips, so that the hollow and muscular part of the thighs may lay smooth and flat to the saddle. The knees must be stretched down and kept back, so as to place the thighs about twenty-five or thirty degrees short of a perpendicular.

This will occasion the rider to sit on his fork or twist, which he should do, and not on his breech—the knee is to be bent, so that the toe hangs perpendicular to the knee—the legs are to hang near the horse's sides, but not to touch—the heel is to be sunk as low as possible, and the toe raised. This will give firmness and strength to the muscles of the legs and thighs.

The body must be upright, and not have the least propensity to drop forward, which, from the situation I have placed the thighs in, it will do, if the loins are not well bent, making the back very hollow, and the shoulders well thrown back, and the chest open :—the head must be upright and firm—the arms, from the shoulders to the elbows, should hang in a perpendicular situation—the elbows bent, so that the left hand should in general be situated about three inches above the pommel of the saddle—the arm, above the wrist, may lightly rest against the

body—and the wrist so bent, that the thumb being upwards, resting on the first joint of the fore-finger, may point betwixt the horse's ears;—the right hand, holding the whip, is to be situated a little lower than the left, not to obstruct the operation of the bridle.—If you sit in the manner above described, you will observe the nose, the breast, the knee, and toe, will form a perpendicular line; the shoulders, elbow, and heel, will likewise be in a perpendicular direction. When the rider can see any part of his foot, he may be assured he is not in the position above described:—the sight of the foot should be obstructed by the knee.

To acquire the true balance in the position directed, I recommend the practice on circles, or what is called the longe; beginning on large circles, and an easy, gentle trot, by which the horse will be so little bent, as scarcely to make a perceptible alteration in the position I have laid down as the fundamental one; but as the circles are contracted, and the pace extended, it will be necessary not only for the body to lean with the horse, but likewise to bend, or be turned in the same direction as the horse's head, which, of course, will be bent a little within the circle: this may be called the first variation. Be mindful to work equally to both hands, and not to have any stirrups till you have acquired a true balance without them.

When the stirrups are first used, they will be found an incumbrance rather than any assistance, and a new difficulty will occur, namely, the keeping the foot in the stirrup. This must be surmounted by practice, observing to bear no more than the weight of your foot in the stirrup, which must be placed under the ball of the foot, and the plying of the instep to the action which the body receives, will keep it there. Till you have acquired this play of the instep, you will find, if your toe be too forward, the stirrup will fall to the instep, and if too back, you will lose the stirrup; but when the foot is in its proper situation, if the toe be raised, the stirrup will not immediately depart from it.

Crave no assistance from the reins to support the balance—let the hand be fixed, and the reins of such a length as to feel and support the horse, but never to hold on.

*On the Hand and its Accompaniments.* The generality of persons are very desirous of obtaining a strong and firm seat.

But the hand, take it in whatever point of view you will, is the excellence of horsemanship. In violent contentions with the horse, the hand deprives the horse of one half of his exertions to throw the rider; otherwise it would be impossible to keep on the back of some horses. In vicious restiveness, the hand is your whole security; it baffles every intention of the horse to foil the rider, by crushing him against carriages, rails, walls, &c. By a judicious use of the powers of the hand, you outmanœuvre every effort of the horse, and subdue him. Thus far your safety depends on your hand.

It may not be improper here to observe, that horsemen (by which I mean those who ride scientifically) always ride with the curb-rein. This and the following is a discrimination, that, perhaps, some of my readers have noticed, that, when an awkward horseman has hold of the curb-rein, and, by too severe a hand, prevents the horse from standing quiet, or moving forward, the good-natured spectators will desire the gentleman to loose the curb, and take hold of the snaffle. Now, this does not imply that the gentleman was wrong, but that he cannot ride sufficiently well to be safely entrusted with the curb-rein.

The method of holding the reins, is that wherein the little finger separates the curb-reins, and the second finger the bridoon-reins. This method is best calculated to ride the united airs or manege lessons, because the bridoon rein is easily detached from the left hand, the reins of the bit shifted to the right hand, and the bridoon to the left, for the purpose of handily changing the air from right to left.

Observe, the whip or switch never departs from the right hand (except while mounting or dismounting); the knuckles are carried upwards, unless you carry your whip erect, for which purpose the thumb will then be carried upwards.

Separating the reins, on several occasions, is very necessary. Two hands can execute more than one; consequently, when a horse refuses obedience to one hand, you take two: hence all young, raw horses are rode with two hands. Lessons for the instruction or improvement of horses, manege airs, or whenever you want to perform to the utmost of your own or horse's ability, you use both hands. You seldom have occasion to take more than one rein in the right hand, which, if a single-reined bridle, you cannot mistake;

but when it is a double-reined bridle, remember you take the right rein only of the bridoon or snaffle in the right hand.

I now come to the operation of the hand; perfection in which is the greatest attainment in horsemanship, and the most difficult to describe.

And first, the hand being connected to the reins, the reins to the bit or bridoon, the bit operating on the bars in the horse's mouth, the bridoon or snaffle operating on the lip; you cannot move the hand, nor scarce a finger, but the mouth is more or less affected thereby, according to circumstances, as will appear hereafter: this is called the *correspondence*.

There are many properties requisite to constitute a good and masterly hand. I call that a masterly hand, which, being not only well formed in itself by tuition, and riding well-dressed or manege horses, will make the rude, untutored mouth partake of the sensibility of the hand, which, in other terms, is dressing the horse: for, since the best dressed horses, when rode by heavy, insensible, or uninformed hands, of necessity depart from their excellence, and become as heavy and stupid as the hand that rides them: so may the tutored hand (not of necessity) depart from its properties, and conform itself to the heaviness and stupidity of the horse's mouth. Hence it frequently happens that horses, which please their owners very much at first, so alter in process of time, from the bad riding of themselves, grooms, or stable-boys, that they are under the necessity of parting with them; while horses that are properly rode, improve and please better.

If the hand is held steady, as the horse advances in the trot, the fingers will feel, by the contraction and dilation of the reins, a small sensation or tug, occasioned by the measure or cadence of every step. This sensation or tug, which is reciprocally felt in the horse's mouth, by means of the correspondence, is called the *appui*; and while this *appui* is preserved between the hand and mouth, the horse is in perfect obedience to the rider, the hand directing him with the greatest ease, so that the horse seems to work by the will of the rider, rather than the compulsion of the hand.

The hand, for preserving a medium effect on the mouth, is to be only half shut; the knuckles next the wrist are to be nearly open. By this means the hand, without moving, can give liberty or restriction, by bracing the muscles, or open-

ing and closing the fingers. This is demonstrable by only placing a rein, piece of tape, or string in your left hand, as directed. Rest the hand on a table, and, with the other hand, stretch the rein on the table as far as the liberty of the left hand will admit; then place the thumb of the right hand on the rein, and, by closing the left hand, you will be able to draw three inches of the rein from under the right thumb.

This shews the hand possesses a considerable power, independent of other aids or assistances, more than sufficient to controul or direct a horse that is termed broke or obedient.

Now the correspondence, as we term it, when we speak of the effective communication between the hand and mouth; the *appui*, when we speak of the quality or strength of the operation in the mouth; the support, when we speak of the effect the hand produces in the position or action, are always to be maintained in the manege, or military riding, and all united paces; and without which a horse is under no immediate controul, as we find in the extended gallop or full speed, where it may require a hundred yards to pull your horse together before you can stop him.

The correspondence being comprehended, the power and effect of the hand, by practice, will soon be felt and discovered. For instance, the hand collecting the reins supports the horse; the legs press the action; the action, by a proper correspondence, produces the *appui*; the *appui* will be strong or light, according to the action or position the horse works in. If it is heavy, from the head being carried too low, and the horse not sufficiently united, raise the hand, and let the fingers, by moving, rather invite than compel the head to rise; the legs, at the same time, pressing the haunches under; by this means the horse will become more united, and the *appui* will be lightened. Should the hand be too straight, or confining to the horse, which it may be, though it does not pull half an ounce, as thus, your collecting the reins to unite the horse, and the horse freely uniting himself, becomes so balanced on his haunches, that he cannot, while your hand supports him thus, though you do not pull in the least at him, disunite himself, nor advance one step; and, should you press him without yielding or dropping your hand, you would compel him to rear.

As the situation of the hand, in point

of elevation, so powerfully operates on the mouth, that every quarter of an inch has a perceptible effect; so has the situation of the hand if carried to right or left. But, to avoid moving the arm or hand as much as possible, the motion of the wrist will produce such positions of the hand, as, being accompanied by the corresponding aids of the body, &c. will effect whatever you require from a proper dressed horse.

Aids are certain positions of the hand, body, legs, and sometimes the switch or whip, which direct the horse agreeable to your will; the hand being the principal: the others are called accompaniments, which give greater power and efficacy to the hand; therefore, as I describe the position of the hand, I shall also describe the accompanying or corresponding aids of the body, legs, &c.

The first position of the hand has been sufficiently described already; it is the thumb upwards, the little finger downwards, so that you can just see the ends of the fingers. The aids applied to this position of the hand, are such as effect the action and position of the horse, as raising the head, working the croup in, &c. &c.

The second position of the hand directs the horse to the right, for which purpose, turn the little finger to the right, the thumb to the left; the nails upwards. This position of the hand will carry the operation of the reins nearly three inches more to the right, by which the left reins will press the neck, and the right reins will be slack. Horses properly broke obey this pressure, and the pressure of the left rein turns the horse to the right, and the right rein directs him to the left. To give greater efficacy to this position of the hand, the body aids by turning to the right; and, if necessary, likewise inclines. The right leg aids the croup, by bending the knee and pressing with the calf of the leg.

The third position of the hand is the reverse of the second, consequently directs the horse to the left; turn the little finger to the left, the thumb to the right, the back of the hand will be upwards. This will carry the operation of the reins to the left, the right reins will press the neck, and the left reins will be slack. The corresponding aid is turning the body to the left, and closing the left leg.

Whether you wheel to the right or left, let the aids of the hands, body, and leg, exactly correspond, and practise as much

to the one hand as the other. I advise to practise slowly at first: a proper restriction in the fingers, and less aid will be required; but when you turn quick, the aids must be proportionably stronger.

Remember, as the horse arrives at the situation you intend him to halt, whether it is a wheel, which is a quarter circle; about, which is half a circle; or about and about, which is a whole circle; the hand, body, and leg, must resume its proper straight position; the hand dropped, and the fingers eased, that the horse may stand quiet.

In wheeling the horse on his fore feet, the hand has to support and confine the fore part, while the heel directs the croup round. The aiding with the leg will induce the horse to advance, if a proper restriction be not put in the fingers; and the moving one end of the lever will shift the other, if not properly confined.

The passive obedience and submission of the horse to these nice restrictions of the hand and heel, is not to be expected from those which have not been properly broke; and these, if not sometimes practised to them, will shew a reluctance to obey; in which case (as I have observed, two hands can do more than one), you take the assistance of the other hand; for, though the delicacy of the performance is interrupted, the obedience must be compelled. The hand to which you would turn is the hand you must take the bridle in, and you take as much assistance from that hand as you find necessary. Should resistance require a powerful operation from this hand, observe, your power to compel the horse to turn increases in proportion as the hand is detached from the body; so that, when you pull in the direction from the horse's mouth to the horse's croup, your power is immensely greater than when you pull in a line to the centre of your body. The assistance of the right heel with the right hand, and the left heel with the left hand, must proportionably be given. Thus, being possessed of power, your discretion must direct you to the use of it.

The fourth aid or operation of the hand, requires the horse to rein back. Little or no alteration from the first position is necessary to effect this: the reins being properly adjusted, the stiffening of the muscles and pressure of the fingers are generally sufficient for proper dressed horses. To give greater efficacy, turn the knuckles a little down, and draw in the belly: the body should, if any, rather

incline forward, which gives the hand a greater effect, without provoking the horse to rear; a circumstance that might occur with horses which do not readily obey the hand, particularly if you leaned back to give power to the hand; and then you might be in some danger, because the body is not in a situation to act as the circumstance requires.

This must be particularly attended to, because, if you attempt to compel the horse back by the power or weight of the body, and he should rear, which is to be more expected than not, the body cannot be brought forward, and you hang on by the bridle; and, should you happen to have the preponderance, you pull the horse backwards on yourself.

The operation of the hand, in reining back, is a kind of invitation. Should the horse not readily obey, play with the mouth by moving the fingers; this will induce the horse to raise his head; gently close your legs to make him unite, and then the pressure of the fingers will constrain him backward. The instant the horse is constrained to back, the body, if in a proper position, will incline forward, and the fingers must be eased. A horse that is properly broke, obeys the lightest pressure of the fingers, and backs without throwing himself off his balance: but the horse that is constrained to back, is overbalanced; and, if the body did not come forward, or the hand relinquish its severity, he must back till he fell: therefore, the instant the horse yields to the hand, the body and hand yield to the horse, that he may recover his balance, and the little alarm occasioned thereby; and then gently invite or press him to back again.

It is to be observed, in reining back, the hand and the heel change their functions; that is, the hand compelling the action, and the heel directing it.

Having gone through the different positions to give efficacy when wanted, without moving the arm, there are still remaining many properties and excellencies, several of which must be obtained by observation and practice, words not being capable of conveying an adequate idea of them.

*Aids, Corrections, Animations, &c. &c.* Being necessitated to give a description of the aids as they accompany the hand, I have but little to add in this place. Aids are the indication of the horseman's will to the horse, and are so called, because they not only require but assist the horse to execute, at the same time they check

or obstruct him from acting contrary. Now, the positions of the body and legs, when they deviate from the fundamental seat, as laid down, for the purpose of giving effect and assistance to hands, are aids; but when, for the purpose of preserving the balance, or maintaining the seat, they are necessary variations of the seat, and will be found as many as the positions the horse can work in: in most instances, they contribute to assist both hand and seat.

The aids of the legs have their progressive strength and effect, and are thus given: the leg being brought nearer the side, is the first degree, or lightest aid; placing the leg further back, with the toe turned out, is the next; the lightest possible touch with the calf of the leg, is the third; and so on, increasing the degree of pressure, according to the strength of aid required, with the toe kept up firm, that the muscles of the leg may be hard and operative. The strongest aid is the scratch, which is thus given:—when the leg is laid on hard without effect, drop the toe; and if the spur is placed in a horseman-like manner on the heel, the rowel of the spur will thereby prick or scratch the horse's side. To this succeeds a correction, by giving the spur sharply.

Aids with the whip are sometimes used to give greater effect to the heel. These are gentle taps with the whip on the hind quarters, and sometimes on the shoulders: when given on the near side, the hand is applied behind the back, with the whip held by the fingers as you would a pen, with the lash downwards; or crossing the bridle-hand before, the whip held with the lash upwards. When aids are properly displayed, they discover the taste and the judgment of the horseman, and have a pleasing appearance.

Corrections are given by the hand; they are likewise given by the whip and spurs. The use we make of the whip and spurs, in common, to quicken and animate a horse, we do not call corrections, though sometimes given with a degree of severity; but when correction is given, it should be for vice or obstinate disobedience, and at such time, and in such manner, that the horse may be sensible for what; and with the intent to deter him from the like again.

Correction as smart and determined as possible, and repeat it sharper, if possible, should he kick at that. By this the horse is made sensible of his fault, and is

punished for it; and without such punishment the horse might be ignorant of doing amiss.

For if we wish to draw a croupade or balotade from a horse, we use a similar method of aiding on the croup to provoke and irritate him to raise it; for which we caress him, to let him know it was what we desired.

The animations of the tongue operate by surprise; it is a sound which all the letters in the English alphabet cannot express, and is produced by placing the tongue against the roof of the mouth, and drawing the air between it.

The noise is better known to the generality of people than I can describe it; it is the most animating sound to the horse the tongue can express; and, when judiciously applied, has its proper effect; but if too much continued, or too frequent, its design is done away, for it no longer alarms or surprises. Hence, you may alternately use your animations to keep up an effect; and, with sluggish horses, you may be necessitated to use the whip and spurs.

Soothings are the reverse of animations, and are used to pacify horses that are alarmed, frightened, or have too much fire or animation in their constitutions. Of all the means we use in dressing of horses, soothings and caresses are the most salutary, and from which no harm can accrue. These dispel their fears and apprehensions; reconcile them to new operations; give them confidence in their master; open their understanding to comprehend his lessons; and make them delight in instruction. The voice soothes by the mildest and softest expressions, such as—So, so, so, so!—poor fellow!—and the like. The hand, by gentle patting, stroking, &c. The body and legs, by a stillness, and relinquishment of all unnecessary firmness; sitting easy, and not moving a muscle.

*On Changes, Volts, &c.* A change is no more than the altering the hand to which you were going, or the foot with which you were leading: but this being done by different tracks or modes, and in several actions and airs, gives consonant names to them, and displays a taste in diversifying and execution.

The long change is crossing the riding house in a diagonal line, the whole length of the house; which, when you are working to the right, you quit the wall at the figure 1, and cross to the figure 3; or quit the wall at the figure 3, and cross to

the figure 1; by which you change the hand to which you were going. In like manner, when working to the left, and you would change to the right, you depart from the wall at the figure 2, and cross over to the figure 4; or at figure 4, and cross over to figure 2; which effects the change.

When working on circles of a large diameter, and you would effect a change, you form another circle of the same dimensions, making a figure of 8; in the intersection of which circles, you change your own and horse's position, by which you work to the contrary hand. These are called *changes large*; consequently, when your circles are so circumscribed that the two do not exceed the width of the riding house, they are *narrow changes*.

An air performed on a circle is called a *volt*; consequently the half circle is a *demi-volt*; the change by the demi-volt is effected when working to the right, as from *a* to *b*. At *b* you quit the line, and work on a demi-volt, which brings you to the point *c*, at which place you change and work to the left. In changing again from the left to the right, you quit the line at the point *d*, work on a demi-volt to the point *e*, change, and work to the right. The changes on the volt are confined to particular airs, as the *passage, terre à terre, and mezzair*. When the volt is complete, make a half stop, change the leg, and work the volt round to the contrary hand, on the same ground as before.

The *change reverse* is worked on traversing lines, and confined to the same airs as the volt; it is reversing your hands, position, &c. consequently the horse's position and foot at every angle.

For a further illustration of this subject, we refer the reader to "Adams's Horsemanship."

MANE is the name by which the long hair is called hanging from the neck of a horse, and extending from the back of his ears to his withers.

MANGE. See DISEASES OF DOGS, under the general head DOG.

MANGE IN HORSES. A cutaneous disease, incident to many domestic quadrupeds, and attended with an eruption and loss of hair. Mr. Ryding's account of this disease is as follows:

The causes of the mange, he says, are sudden changes of temperature, hot stables, bad diet, joined to want of cleanliness. The perspirable matter being

never properly removed by friction, and frequently being mixed with dust, &c. completely plugs up the external vessels, whereby they become obstructed, and a diseased action takes place. It may also be caused by infectious matter coming in contact with the skin; as when a sound horse rubs himself against the stall in which a mangy horse has been kept.

The principal symptoms of mange are, the horse growing very thin, without any apparent cause, attended with a staring of his coat. This is soon followed by eruptions, which discharge a thick yellowish matter, forming a kind of scurf, which peels off, and is succeeded by fresh eruptions, and the hair falls off. This, though partial at first, soon spreads all over the body, is attended with an itching, which causes the horse to rub against every thing he comes near.

With due attention to cleanliness, the following medicines will very soon remove this disease:

Take of Prepared hog's lard, one pound;  
Sulphur, half a pound;  
White hellebore, in fine powder, three ounces;  
Mix, and add  
Olive oil sufficient to make soft ointment.

A moderate quantity of this ointment may be rubbed well, with the hand, all over the affected parts, or where there is the least appearance of any eruption; and this should be repeated after an interval of three days. Two or three applications of this ointment, Mr. Riding says, are generally sufficient to complete the cure.

The following medicine, however, may be given with advantage in this disease. It will be found excellent for removing cutaneous obstructions, improving the appetite, and promoting condition.

Take of Antimony in fine powder, eight ounces;  
Grains of paradise in fine powder, three ounces.  
Mix, and add  
Venice turpentine, sufficient to form the mass of a proper consistence, and divide it into twelve balls. One of them may be given every other day.

Mr. Denny says the cure ought to commence with taking away four or five pints of blood, if the animal's strength will allow it; (by the way, a very material proviso; as promiscuous bleeding is too commonly practised in cutaneous

diseases): and we are advised to give the following ball in the evening:

Take of Nitre, in powder,  
Resin, in powder,  
Castile soap, of each half an ounce;  
Camphor, in powder, one drachm;  
Honey, enough to make a ball.

He recommends particular attention to be paid to diet, exercise, and good grooming. The food, he says, ought to be of the best quality, and given in liberal quantities. The bowels should be kept open with mash, in which an ounce of nitre is dissolved. A small rowel may likewise be placed in the chest. The affected part should be well washed with a strong solution of soft soap, and afterwards rubbed, morning and evening, with the following ointment, for a week:

Take of Flowers of sulphur, four ounces;  
Hog's lard, three ounces;  
Quicksilver ointment, two oz.  
Mix them.

This ointment may be continued every other day, until the disease gives way, or is entirely removed. Two or three doses of mild physic are afterwards recommended, and then the following ball, every night, for a month:

Take of Ethiop's mineral,  
Crude antimony, in powder,  
Cream of tartar, of each half an ounce;  
Honey, enough to make a ball.

When the disease is removed, which a perseverance in the above method of cure, Mr. Denny asserts, will effect, the horse should be turned out to grass, if at a proper season of the year; but a salt marsh should be preferred.

Mr. John Lawrence is disposed to consider, as the principal causes of this disease, neglect and insufficient diet. He says, "if you keep a horse very poorly, he will be mangy; but if you line his inside well, however you may neglect him externally, he will not generally be mangy." He excepts, however, the case of the horse's being employed by a lime-carter. "A few years ago (says Mr. L.) on the recommendation of certain stable economists, and in the teeth of common sense and my own experience, I undertook the feeding of labouring cart-horses upon carrots and oat-straw, and other vegetable trash, for which I was properly rewarded, in a short time, by the trouble of curing them all of the mange. This disease, or morbid result of poverty and filth, suffered to arrive

## M A N

at an extreme degree of inveteracy, degenerates into a marasmus or consumption, absolutely incurable.

“The mange, if a mere cuticular affection, induced by an external cause, or caught by contact of a diseased horse (which last may happen from rubbing against such an one, or wearing infected clothes, or standing in an infected stall), is speedily cured by external applications, with the aid of a dose or two of physic; but when the disease originates in the mass of humours being vitiated, the cure will require a greater length of time, and a larger share of medical assistance.”

In a slight case, the treatment advised is strong tobacco infusion with one third part of stale urine, to wash the affected places. But as an efficacious unguent,

Take of Quicksilver ointment, half a pound;

Brimstone, finely powdered, four ounces;

Black soap, two ounces;

Crude sal ammoniac, an ounce and a half;

Oil of bays or turpentine, enough to make an ointment.

Or,

Take of Tar,

Gunpowder finely powdered,

Black soap,

Oil of turpentine, of each about equal quantities.

Mix into an ointment.

In cases of long standing, where the ulcerations are extremely foul, and resist all moderate applications, the following ointment, Mr. Lawrence says, may be ventured on:

Take of Burnt alum,

Borax, in fine powder, of each two ounces;

White vitriol,

• Verdigrease, powdered, of each four ounces.

Put them into a pot over the fire with two pounds of honey, or of lard and honey equal parts. Stir them till they are well incorporated, and when cold, add of

Aqua fortis, two ounces.

The first of these ointments, however, Mr. Lawrence conceives to be equal to almost every case, being used at night;

**MARE.** The well-known feminine of the horse, but not held of equal value with the masculine in respect to the gender, which is not only troublesome, but found to be productive of temporary debility at certain seasons of the year. Mares are evidently weaker, and less

## M A R

especially if the sores be washed twice a day with the following lotion:

Take of Muriated quicksilver (sublimated), in powder, half an ounce;

Dissolve it in a pint and a half of boiling water.

Or perhaps the following may deserve the preference:

Take of Muriated quicksilver,

Muriated ammonia (crude sal ammoniac), of each from two to three drachms;

Boiling water, three half pints.

Mix.

This kind of treatment, modified at the discretion of the practitioner, will succeed in cases of mange affecting other animals.

**MANGER.** The name by which the trough is called that is fixed in all stables. It is an excellent and healthy custom to let all mangers, in constant use, have a substantial scrubbing with soap, brush, and boiling water, once a month.

**MARCH.** At this period field sports are drawing to a close. The pursuit of the fox is continued during the whole month, and excellent runs are frequently obtained; but the huntsman should, if possible, ascertain the sex of the chase; since if it be a bitch fox, it may be in a state of gestation, and infinite mischief to future sport may therefore result: at the same time, it will not be able (particularly if far advanced) to stand long before the hounds, and will consequently afford but little diversion.

The hare is pursued at the commencement of this month; and after killing what is called a *March hare*, both hunting and coursing cease.

This is the period for breaking young pointers and setters; as the birds having paired, will not easily take wing, but will, on the contrary, run much, and thus afford the dogs an excellent opportunity of acquiring a knowledge of their business. The dogs should, however, wear muzzle pegs, to prevent them chopping young hares, many of which will have been dropped before the end of the month.

Otter hunting, if the weather be fine, may be commenced; and the same observations may be applied to angling.

adequate to severe work, at certain periods ; which, perhaps, is the principal reason why geldings are so generally preferred, as far as they can be obtained. Notwithstanding this partiality, mares are not without their advocates, and have their conveniences : in cases of lameness, or other occurrences in the long list of casual ills, they, of course, become appropriate to the purpose of propagation, without much loss being sustained. Those, however, who expect to derive either pleasure, emolument, or a gratification of ambition, from breeding, must be a little prudent and circumspect in the shape, make, distinct points, and general symmetry, of the mare, before they too hastily embark in so critical, and so truly expensive, an undertaking. Although it is a maxim universally admitted, that an equal degree of precaution should be used in respect to the horse, it is doubly and trebly necessary with the mare ; because strict observation has demonstrated, that nearly or full two out of every three foals display, in their appearance, more of the dam than the sire : and that there are more fillies than colts fallen every year, will not admit of a doubt.

A variety of opinions are held, and occasionally propagated, upon the best and most proper age for putting a mare to the horse : that a filly, covered in her third year, will produce a fine healthy foal in her fourth, is sufficiently known ; and that brood mares bring forth excellent stock from their twentieth to their twenty-fifth year, is equally true ; but if the two extremes are avoided (when it can be conveniently done) the produce may most likely come some few shades nearer perfection. In the first instance, it is fair to infer, that the component parts may not have reached the extreme points of strength and maturity ; and that in the latter, from the natural effect of age, the frame is verging upon decay ; and that the lacteals, from whence the nutriment for the foal is to be obtained, must be contracted in proportion.

The best and most approved season for letting the mare take the horse, where the produce is bred for general purposes, is from the first week in May to the last in June ; as then the offspring is dropt in April or May in the following year, which are the most proper months a foal can fall in, to have the advantage of all the summer for growth and expansion, preparatory to the drawback of weaning, and the ensuing severity of the winter. Mares during the time of gestation, are liable, but very little subject, to abortion ; reasonable work and moderate exertions, affect them but slightly in that way ; nor does the disappointment but seldom happen, unless by some severe, cruel, or inhuman treatment. Mares are the most uncertain of all animals in bringing forth from the time of conception. Numerous attempts have been made to discover the precise time of a mare's carrying her foal, which, however, does not yet appear to have been ascertained to a certainty. Long-standing opinions and authority, transmitted from one posterity to another, has established at eleven months, and as many days as the mare happens to be years old : strict attention, in a variety of instances, to both the lunar and calendar months, has proved the uncertainty of this calculation, and left them,

in these events, dependent upon neither one nor the other. Certain it is, they go many days longer with a colt foal than they do with a filly; and cases frequently occur, where a mare carries her foal within a few days of the twelve months.

**MARK!** A term used by sportsmen, particularly in cover shooting, where they are necessarily separated from each other; when one of the party having pushed or sprung a pheasant, or flushed a cock (at which he either did not get a shot, or missed), he then vociferates *mark!* in hope that his companion or attendant may get a shot, or *mark* the spot where the bird alights. The term is used in all kinds of shooting—in the case of hare, another word is generally added, as *mark low!*

**MARK.** In stable language, a horse marks, when he shews his age by a black spot, like the bud or eye of a bean, which appears, at about five and a half, in the cavity of the corner teeth, and is gone when he is eight years old: then he ceases to mark, and they say, *he has rasé.*

Gibson says, “with regard to the marks of horses, arising from their colour, some have reckoned them to be lucky or unlucky, as they happened to be this or that way marked. Others have even been so curious as to lay much stress upon them, and to denote all the good or ill qualities of a horse from his marks: but, however this may be, certain it is, that a horse always looks the more beautiful for being well marked; and a horse without marks always has a deadness in his aspect.

A star is the most common of all marks; and where that is wanting, it is often supplied with an artificial one. When the white descends pretty broad toward the nose, it is called a blaze; when it descends into a smaller line, it is called a snip; and when most of a horse's face is white, he is then said to be bald. All these marks are beautiful when they are not in extremes, for a very large star is not reckoned so beautiful as one that is of a moderate size; neither is that baldness that spreads over a horse's whole face and cheeks any way becoming, as it gives him the look of an ox: and such horses are often plain-headed. When the white of a horse's face is divided in the middle, or any other part, or when a blaze or snip runs awry to one side, it looks somewhat disagreeable, though perhaps it may be no diminution to a horse's goodness. Some black horses have their stars or

blazes fringed round with a mixture of black hairs, which looks very well, only such horses are apt soon to grow grey faced, and look old; as are some of the browns. But when the bays and sorrels have their stars or blazes fringed, it is generally with their own colour, or lighter, and seldom has that effect.

As to the white marks upon the feet and legs of horses, they usually correspond with the marks upon their faces. Bald horses have generally a good deal of white about their legs, and often all four are white, which in them is not unbecoming. Horses with large blazes have often all their four feet white also; but a horse that has no marks on his face, or but a small one, never looks well with white legs, especially when the white rises above the fetlock: on the other hand, a bald horse, or any horse that has a blaze, without any of the feet white, is but ill marked; and therefore a horse always looks best when there is this correspondence and agreement in the marks: a horse that has his near-feet both before and behind white, and his off-feet without any white, is but indifferently marked. The same where the marks are only on the off-feet, without any white on the near-feet.

Some dislike horses for being traversed, or cross-marked, viz. the near-foot before, and the off-foot behind, white; or on the contrary, when the off-foot before, and the near foot behind, are only white. Those are usually judged to be the best marked that have only the near-foot behind white, or both feet behind white; or where the near-foot before, and both the hind feet, are white; especially when, at the same time, a horse has a large radiated star, or small blaze, on his face. When the white about the feet is indented with black, or any other colour, towards the coronet, these feet are thought to be generally good; and when the coronet is spotted like ermine, the mark is so much the better: but where a horse's pasterns, hoofs, and all his four legs, are white, especially when the white rises above the knees or hocks, it looks ugly; and a horse thus marked has too much of the pye-bald, consequently seldom fit for a gentleman's use.

The feather is another sort of distinc-

tion, which we often observe, especially upon stallions; and such geldings as have short hair, and are finely coated. Some are of a round figure, and some long and narrow, in the true penniform shape, or like an ear of barley. The round are often on the forehead, sometimes on the breast and shoulders, and look like embroidery. Those on the neck lie immediately under the mane, and run down towards the withers. When the feather happens on both sides the neck, the mark is reckoned exceedingly good and beautiful. Sometimes feathers run down the fore-arms, and sometimes on the thigh, and towards the dock; and they may be observed on several other parts of a horse; but, wherever they happen to be, they are almost always reckoned signs of goodness; and some of them are exceedingly beautiful.

**MARKS.** The foot-prints or treadings of wild beasts.

**MARSH, OR SALT MARSH.** A kind of pasture found to be particularly favourable to the recovery of sick and lame horses, under certain circumstances. The experienced Gibson says the salt marshes along the river Thames are as good pasture for horses as any about London; and there many horses run all the year round. Though the air arising from the marshes is very injurious to human constitutions, and subjects them to annual returns of the ague, and some other maladies; yet it has no such effect upon brute creatures that feed on them, which may perhaps be owing to the quality of the salts, with which that grass is more or less impregnated. The marsh soil is for the most part a composition of a very fine light mould, mixed with sand, covered all over with a fine trefoil, which sows itself and grows extremely thick in some places, as we see it on some parts of our finest commons. If the rains fall never so heavy, the ground being open drinks it up immediately, so that the cattle always lie dry upon it, even in winter, when most other places are potchy, which is one of the greatest benefits of all others to horses at grass. They purge more there, both by dung and urine, than on any other pasture, and afterwards take on a firmer flesh; so that those who send their horses there only to cleanse them, and after purging remove them to other pastures, unless it be for some particular convenience, Gibson says, are greatly mistaken; for he has known horses that have run

there summer and winter, with as few accidents as happen to horses any where else. Four-and-twenty hours' constant rain in the grass season will often bring up grass in the marshes, unless the weather be extremely cold. And horses often grow fat on the best marshes, when they are eaten so bare, or burnt up in dry weather, that scarcely any grass is to be seen on them. In winter some never house them, but let them run abroad and take their chance in the open fields, where there are neither trees nor hedges to cover them, and yet they seldom suffer any thing from the extremity of the weather; nor, unless the ground be covered deep with snow, do they allow them any dry forage. Yet these for the most part appear in good case, even in the months of December and January, when they have nothing to feed on but the roots.

All the water they have to drink is for the most part brackish, which at first is not very agreeable to horses that have not been used to it, but afterwards they come to relish it as well as any other. The greatest danger on the marsh ground is from the deep ditches made to take off the spring tides, some of which have their bottoms full of a kind of loam, engendered by the weed which comes into them in great plenty at high water. And if a horse that is a stranger to these grounds happen, in leaping, or any other way, to step into one of them, he may run the hazard of being lost unless he be discovered in time. Sometimes horses have been washed away with the spring tides by going too near the dykes; but these accidents seldom happen, not only because the marsh-men are always upon the watch at such times, but most horses have sagacity enough to avoid the danger.

It is certain that there have happened some instances of horses that have soon died there. These, however, are but few; yet no wonder, considering many are carried there, as consumptive people are sent to the hot-wells, when all expectations from the common means are given up. Nevertheless great numbers of horses recover in the marshes beyond all expectation, in chronical distempers, especially where the viscera happen to be sound, or but little diseased. "Nay, (says Gibson) I may venture to say, when a distempered horse dies suddenly at the marshes, it is a good riddance to the owner." Those who have not the conveniency of the marshes, may turn their horses out upon some other good pasture in a moderately

warm soil, where the grass is fine, and has never been forced with dung or other unkindly manure, and where there is good water and proper shelter.

**MARSK.** A horse whose celebrity arose more from chance than any peculiar merits of his own. He was bred by the then Duke of Cumberland; was foaled in 1750; got by Squirt, (who was got by Bartlet's Childers;) dam by Blacklegs, grand-dam by Fox-cub. Although his blood and racing ability were fairly admitted, yet, so far from having acquired any reputation as a stallion, he was permitted to cover common mares at the Lodge, in Windsor Great Park, for only half-a-guinea, which was the groom's fee. Precisely at this period (in the year 1763) Spiletta, the dam of Eclipse, having proved barren for two or three years in

succession, a new experiment was made, and she was covered by both Shakespeare and Marsk in the same season; when stunted, and some time after perceptibly in foal, it was uncertain which was to be declared the sire, till the produce falling to correspond with the last leap of Marsk, he became (from Eclipse's astonishing powers) loaded with honours, publicly acknowledged the sire with an enhanced reputation, and a constantly increasing seraglio; from which time he continued a stallion of the first eminence, and produced a progeny of winners by much too long for introduction under this head. Spiletta afterwards produced Proserpine by Marsk, foaled in 1766; and that well-known horse Garrick, foaled in 1772; both excellent runners.

**MARTIN OR MARTERN.** This animal is about eighteen inches long, of a dark chesnut colour, and has a yellow throat and breast. It frequents the pine forests of all the northern regions, but particularly of America; and is found in many parts of England.

Its general retreat is in the hollow of some tree; so high up and in other respects so situated, as to afford it perfect security. The nest of the squirrel is generally preferred: of this the martin dispossesses the ingenious architect by killing him. The martin now enlarges the dimensions of its new habitation; lines it with softer materials, and in that secure retreat brings forth its young.

Its courage is so great that it will attack animals much larger and stronger than itself. But notwithstanding this ferocity of disposition, the martin is easily rendered docile. Gesner says he kept one which was extremely playful and entertaining. It used to go to the houses of the neighbours, and always returned home when it wanted food. It was particularly fond of a dog with which it had been bred up; and would play with him as cats do, lying on its back, and pretending to bite him. Buffon had one, which, though it had lost its ferocity, did not however discover any marks of attachment, and continued so wild as to require being chained. It frequently escaped from its confinement: at first it returned after an absence of some hours, but without appearing pleased: the time of absence of each succeeding elopement gradually increased, and at last it took a final departure. During its confinement, it sometimes slept for two days without intermission. When preparing for sleep, it formed its body into a circle, and hid its head, which it covered with its tail.

These animals have a musky sort of smell, which to many persons is highly agreeable. Their cry is sharp and piercing; but is never uttered except when in pain or distress. Their principal food consists of rats, mice, and other small quadrupeds; poultry, game, &c. and they are remarkably fond of honey. They are very destructive to game, particularly to pheasants.

The female produces three or four young, which soon arrive at a

state of maturity. She is able to afford them but a small quantity of milk ; but she compensates for this defect by bringing home birds and small animals alive, and thus she early accustoms her offspring to a life of carnage and plunder. As soon as the young are able to leave the nest, she leads them through the woods, where they begin to seize on their prey and to provide for themselves.

Fox-hounds are sometimes entered at the martin ; and though Beckford seems to approve of it, we are by no means disposed to recommend it, being decidedly of opinion that it is the best plan by far to enter young hounds at their own game ; or, in other words, to stoop them to that scent, which they are intended afterwards to pursue.

**MARTINGAL.** The article so named is of two kinds ; one of which is termed a headstall martingal ; the other, simply, a martingal : each consists of a long strip of leather, about an inch and a half wide, passing between the fore legs, with a loop or wide noose at its extremity, through which the hinder girth is to pass, and by which it is secured at that end : at the front of the breast it divides into two equal branches ; and having rings at the extremity of each, they are slipt upon the bridoon (or snaffle) rein, and are used to keep down the head of a hard-mouthed or star-gazing horse. The headstall martingal is of similar construction, except its having a headstall the same as a bridle, to which the divided branches before described are united at the cheek on each side ; but this is a hazardous practice, and

should only be used with colts in breaking ; for if a horse once stumbles in action, he is so confined, that his sudden exertion to raise his head, and to recover himself, being counteracted, he almost inevitably comes to the ground.

**MASH.** A kind of diet pudding sometimes given to a horse. It is made of half a peck of ground malt, put into a pail, into which as much scalding water is poured as will wet it very well. When that is done, stir it about till by tasting you find it as sweet as honey ; and when it has stood till it is luke-warm, it is to be given to the horse. This is mostly used after a purge, to make it work the better ; or after hard labour ; or in the time of sickness. Mashies are made with bran in the same manner.

**MASTIFF.** Mastiffs are said to be peculiar to this country, where they are principally used as watch-dogs, for which purpose they are superior to the bull-dog, as they are more watchful and more sagacious. The dog formerly used in Germany for the pursuit of the boar was something of the mastiff kind, and they are still to be found in that country, particularly in Hungary.

The English mastiff is extremely bold and courageous. Stow relates an instance of a contest between three mastiffs and a lion, in the presence of James I. One of the dogs being put into the den, was soon disabled by the lion, which took him by the head and neck and dragged him about. Another dog was then let loose ; and was served in the same manner. But, the third being put in, immediately seized the lion by the lip, and held him for a considerable time, till being considerably torn by his claws, the dog was obliged to quit his hold. The lion, greatly exhausted by the conflict, refused to renew the engagement ; but, taking a sudden leap over the dogs, fled into the interior part of his den. Two of the dogs soon died of their wounds : the last survived, and was taken care of by the king's son ; who said, " He that had fought with the king of beasts should never after fight with any inferior creature."

The English mastiff is a very powerful animal, and in general very courageous, but his courage cannot be always depended on, like that of the bull-dog.

A most extraordinary instance of memory in a mastiff is related by M. D'Osbonville. This dog, which he had brought up in India from two months old, accompanied him and a friend from Pondicherry to Bangalore, a distance of more than three hundred leagues. "Our journey (says he) occupied nearly three weeks; and we had to traverse plains and mountains, and to ford rivers, and to go along several bye paths. The animal, which had certainly never been in that country before, lost us at Bangalore, and immediately returned to Pondicherry. He went directly to the house of M. Beylier, then commandant of artillery, my friend, and with whom I had generally lived. Now the difficulty is, not so much to know how the dog subsisted on the road, for he was very strong and able to procure himself food; but how he should so well have found his way, after an interval of more than a month! This was an effort of memory greatly superior to that which the human race is capable of exerting."

We are told that a large mastiff, belonging to the late M. Ridley, Esq. of Heaton, near Newcastle, being frequently molested by a mongrel, and teased by its continual barking, at last took it up in his mouth by the back, and with great composure dropped it over the quay into the river, without doing any further injury to an enemy so contemptible.

**MATCH IN RACING** is a bet made between the owners where only two horses are concerned, one of which must become winner.

**MATCH'EM.** A bay horse, foaled in 1748, bred by John Holme, Esq. of Carlisle, and sold to William Fenwick, Esq. of Bywell, Northumberland.

Match'em (own brother to Changeling) was got by Cade; his dam by Partner; grand-dam (Mr. Vane's Little Partner's grand-dam) by Makeless; great-grand-dam by Brimmer; great-great-grand-dam, (Trumpet's dam, and great-grand-dam of Cartouch) by Mr. Place's White Turk, a daughter of Dodsworth, out of Mr. Layton's Violet Barb Mare.

In 1753, Match'em won the subscription purse of 160l. 5s. for five-year olds, 10st. four miles, at York, beating Mr. Shafto's Barforth Billy, by Forester; and Mr. Watson's Bold, by Cade:—2 to 1 on Match'em. He also won 50l. for five-year olds, at Morpeth, beating Mr. Shafto's Blameless, by Forester. In 1754, Match'em received a 20l. premium, and won the Ladies' plate of 126gs. for five-year olds, 9st. and six-year olds, 10st. four-mile heats, at York, beating at two

smart heats, Mr. Thornton's Sedbury, 5 years old:—The odds were greatly in favour of Match'em. He also won the Ladies' Plate of 80l. at Lincoln, beating, at two heats, the Duke of Ancaster's Martin, and Mr. Smith's Skim: and walked over for 50l. at Morpeth.

At Newmarket in April, 1755, Match'em won the 50l. for six-year olds, 8st. 7lb. and aged, 9st. B. C. beating Mr. Bowles's Trajan, 6 years old; and distanced two others: he won this race exceedingly easy; but, it was said, that Trajan ran faster than Match'em up the Chalk-Jade, but could not maintain it: they ran the heat in 7 minutes and 20 seconds, carrying 8st. 7lb. each:—The odds were 5 and 6 to four on Match'em, and large sums were lost on the contest. The friends of Trajan were not satisfied that Match'em was the best horse, from the very indifferent condition of Trajan, who was only taken from grass the December before, and had had but one sweat during the whole winter; and when he came to Newmarket was injudiciously hurried with the strongest exercise to prepare him for running. On this, Mr. Fenwick offered to run Match'em against any horse in Eng-

land for the whip, which was accepted by Mr. Bowles to run Trajan against him, at Newmarket following spring meeting.

In August, Match'em received a 20l. premium, no horse entering against him at York.

At Newmarket in April, 1756, Match'em and Trajan met, according to agreement, at 10st. each, for 200gs. each, and the whip, B. C. when Match'em proved the winning horse. The odds at starting were 2 to 1 on Match'em; over the Flat, 5 to 1 on Trajan; but at the Turn of the Lands, 100 to 1 on Match'em, who then made his run; and it was observed, that Mr. John Singleton, who rode him, judged perfectly right in keeping behind, and fretting the fiery Trajan, till he had got him out; and although Trajan had the lead upon the Flat, to maintain it he was obliged to be whipped.

In the second spring meeting, Match'em started for the jockey-club plate, and was beat by Spectator and Brilliant; Match'em being three times only third; Sweepstakes, Whistlejacket, and Crab, also started. The odds at starting, for the first heat, (which was run in 7 minutes, 52 seconds and a half) were 2 to 1 against Match'em, 3 to 1 against Whistlejacket, and 4 to 1 against Brilliant. The odds for the second heat, (which was run in 7 minutes and 40 seconds) 2 and 3 to 1 against Brilliant, 4 to 1 against Spectator, and Match'em scarcely named. And the odds for the third heat, (which was run in 8 minutes and 5 seconds) were 2 to 1 on Spectator, and 6 to 1 against Whistlejacket, who made good running for the last heat. After which, Match'em won 60gs. at Newcastle, beating easy Mr. Swinburn's Drawcansir, and Mr. Parker's Full-Moon.

At Newmarket second spring meeting, 1758, Match'em started for the jockey-club plate, and was second to Mr. Greville's Mirza; Sir James Lowther's Jason, third; Mr. Panton's Feather, fourth; and Mr. Vernon's Forester, fifth. At starting, even money against Feather, 6 to 4 against Jason, 6 to 1 against Mirza, and 10 to 1 against Match'em. Though Mirza gained advantage at starting, which he kept above three miles, yet Match'em ran an excellent honest horse, and was beat with great difficulty: and as large sums were depending between Match'em, Jason, and Feather, it was observed, "That the friends of Poor Old Match'em, not only *combed the golden-fleece*, but *dressed the feathers very handsomely*."

In September following, Match'em won 50l. wt. 9st. at Scarborough, beating easy Mr. Jolliffe's Foxhunter, and Mr. Harvey's Sweepstakes. At starting, 10 to 1, and after the heat, 20 to 1, on Match'em. The above were the only times of his running.

Match'em then became the leading stallion in the north of England, where he covered with uncommon success, till death put a period to his existence, which happened in the 33rd year of his age, at Bywell in Northumberland, on Wednesday, the 21st of February, 1781.—A few days previous to his death, he covered a mare which proved in foal.

Match'em first covered at 5gs.; in 1765, he was advanced to 10gs.; in 1770, to 20gs.; in 1775, he was stinted to 25 mares, (with those of his owner) at 50gs. each, exclusive of the groom's fee.

It has been said, and there can be little or no doubt of the truth, that Mr. Fenwick cleared by Match'em, as a stallion, upwards of 17,000l. which was about 6,000 more than Mr. Martindale of St. James's Street, London, gained by the celebrated Regulus.

MAY. In some places (but I hope very few) it is the custom to kill a *May fox*; generally speaking, however, fox-hunting closes at the beginning of April; therefore, with the exception of angling and otter-hunting, field sports have ceased.

Partridges and pheasants deposit their eggs during this month, and commence the process of incubation.—The hopes of the shooter depend much upon the state of the weather during the months of May and June:—if it be warm and dry, an abundance of both partridges and pheasants may be very confidently anticipated. On the contrary, should much rain fall, the young birds will suffer accordingly.

Young grouse will appear this month, some strong, and perhaps on the wing.

An abundance of young hares are brought forth during this month. The same remark will apply to young foxes.

MERCURY was the name of a horse, that, as a racer, and afterwards a stallion, stood very high in sporting estimation. He was bred by the late Colonel O'Kelly; foaled in 1778; was got by Eclipse out of a Tartar mare, who was likewise the dam of Whitenose, Maria, Antiochus, Venus, Jupiter, Adonis, Lilly of the Valley, Volunteer, Bonnyface, and Queen Mab. After having acquired considerable celebrity as a good runner, and proved himself equal to any horse of his time, he became a favourite stallion in

the possession of Lord Egremont, where he produced a numerous progeny, including a very great number of winners, many of much note; and, amongst the rest, the following celebrated horses, some of whom were stallions of high reputation: Calomel, Sublimate, Hypolyto, Mercurio, Old Gold, Precipitate, Quicksilver, Young Mercurio, Felix, Cinnabar, Mother Bunch, Hermes, Pill Box, Silver, Transit, Gohanna, Caustic, Stadtholder, Buckingham, &c. &c.

**METTLE.** A cant term used by dealers in horses to express a great deal of spirit, vigour, or *heart*, as they otherwise call it. There is great difference between a mettled horse, a horse of vigour, and a fiery horse; but as this is not sufficiently attended to by gentlemen in their purchases of this animal, some general rules for the distinguishing real vigour in a horse may be acceptable.

When a horse is standing still, the rider who has a mind to try whether he has vigour in him should keep him fast with the bridle-hand, and apply the spurs to the hair of his sides; this is called by horsemen, pinching. If the horse is impatient under this, gathering himself up, and endeavouring to go forward, and champs upon the bit, without thrusting out his nose, it is a sign of vigour and right mettle in him. Some caution is to be used, however, in judging by this, to distinguish between a horse that has vigour really in him, and one that has only a fine skin, and is rather ticklish than mettled. This is the case with a great many horses, and is found by their being very sensible of the touch of the spur, and shewing the appearance of a great deal of mettle and vigour when touched, but immediately losing the apprehension of it. These are, in fact, of a dull

disposition, and only have a tender skin.

The mettled horse is to be highly valued; but the fiery one is good for nothing. A horse that is truly vigorous should be calm and cool; he should in general move on patiently, and only shew his mettle when it is required of him.

The surest method is to choose such horses as are extremely apprehensive of strokes, and are afraid at the least appearance of their coming. These, at only the closing of the legs and thighs, seem to be seized with fear and alarm, but that without fretting or fierceness. A horse that walks deliberately and securely, and that without requiring the whip too often, will go on briskly and without fretting; will go from the walk to the gallop, and as easily from the gallop to the walk again, and continually champs upon the bit, and trots with freedom, upon the shoulders easily, and snorting a little through his nostrils: this is generally a creature of true mettle and vigour, though it does not rise to such a fierceness as is troublesome or dangerous. If to these good qualities a horse be well upon his haunches, and have a light and easy step, his head well placed and firm, and the feeling of his bit equal and just, the buyer seldom need to complain of the price.

**MEUSE.** A small hole made in the bottoms of hedges by hares, through which these animals frequently pass; and where the poacher generally places his wire snare or purse net.

**MEWING** is an old forest term for a stag shedding his horns.

**MEWS.** A receptacle for horses and carriages. The buildings consist of stables and coach-houses with conveniences above for the residence of coachmen and their families.

**MIGRATION OF BIRDS.** This subject is involved in a considerable degree of obscurity; and in all probability will for ever remain so; sufficient, however, is known on the subject to render it highly interesting. Such birds only as migrate to great distances are denominated *birds of passage*; but most birds, although they do not go to places far remote from their former habitations, in some degree, migrate. At particular times of the year, many kinds remove from the more inland districts towards the shores. The time of these flittings are observed with the most astonishing order and punctuality. Pope has the following beautiful lines on the subject:—

“ Who taught the nations of the field and wood  
To shun their poison, and to choose their food?

## M I G R A T I O N

Prescient, the tides or tempests to withstand,  
 Build on the wave, or arch beneath the sand?  
 Who bid the stork, Columbus-like explore  
 Heav'ns not his own, and worlds unknown before?  
 Who calls the council, states the certain day,  
 Who forms the phalanx, and who points the way?  
 See then the acting and comparing powers!  
 One in *their* nature, which are two in *our's*;  
 And Reason raise o'er Instinct as you can,  
 In *this* 'tis God directs, in *that* 'tis man."

The secrecy of the departure of birds, and the suddenness of their re-appearance, have given rise to various conjectures. Much of this difficulty arises from our not being able to account for their means of subsistence during the long flights of many of the birds, which are obliged to cross immense tracts of water before they arrive at the place of their destination. Accustomed to measure distance by the speed of those animals with which we are well acquainted, we are apt to overlook the superior velocity with which birds are carried forwards in the air, and the ease with which they continue their exertions for a much longer time than can be done by the strongest quadruped. Childers, one of the swiftest race horses, went at the rate of one mile in a minute, having in twenty seconds run one third of a mile; he also carried nine stone two pounds, four miles in six minutes and forty eight seconds.—Firetail and Pumpkin ran a mile in a minute and a half; but these efforts, great as they certainly are, were not of long duration, and were attended with a total want of power to continue them. But the case is very different with birds: their motions are not impeded by debility, which is the constant attendant upon the uncommon exertions of quadrupeds and of men: they glide through the air with a quickness superior to that of every quadruped; and they can continue on the wing with the same speed for a considerable length of time. Suppose a bird to fly half a mile in a minute for twenty-four hours; in that period, it will have gone over an extent of more than seven hundred miles, which is sufficient to account for almost the longest migration: and if aided with favourable currents of air, which, when in their highest flights, from the appearance of the atmosphere, the clouds, direction of the winds, and other causes, they can apply by that instinctive knowledge which regulates their movements, the journey may be still more speedily performed. There are some of these migratory birds, which, beyond all question, move through the air much quicker than at the rate of half a mile in a minute; for instance, the swallow tribe, the cuckoo, the snipe, the woodcock, &c. and these, it may easily be imagined, find no great difficulty in reaching their place of destination; but the case is very different with some others; such as the quail, the land rail, &c. which appear to have the same journey to perform with very inferior powers.

However, the body of birds in general is so shaped as to dispose it most readily for flight; its make is full of airiness and symmetry; its plumage is well adapted to protect it from the inclemency of the atmosphere through which it passes; and indeed it seems every way

## M I G R A T I O N

calculated for moving with the utmost rapidity through that thin and subtile fluid, the air.

The bones of a bird, according to the observation of the late Mr. John Hunter, are hollow and contain air, which he imagined might be intended to assist the animal in the act of flying, by increasing its bulk and strength without adding to its weight. The internal structure of birds is no less wisely adapted. The lungs are placed close to the back bone and ribs; the air, entering into them by a canal from the windpipe, passes through and is conveyed into a number of membranous cells, which lie upon the sides of the pericardium, and communicate with those of the sternum. In some birds, these cells are continued down the wings, and extend even to the pinions, thigh-bones, and other parts of the body, which can be filled and distended with air at the pleasure of the animal. It seems to be evident, that this general diffusion of air through the bodies of birds is of infinite use in assisting respiration during the rapidity of their flight.

It has been asked whether this universal dispersion of air through their bodies does not account for the superior heat of this class of animals? The separation of oxygen from respirable air, and its mixture with the blood by means of the lungs, is supposed by Dr. Crawford to be the efficient cause of animal heat.

The steerage of a bird in its flight is effected partly by the wings, but in a principal degree by the tail; and hence we meet with a circumstance not a little remarkable. Birds with *long legs* have *short tails*; and, in their flight, they place their legs close to their bodies, at the same time stretching them out backwards as far as they can. In this position the legs extend beyond the rump, and become the rudder; supplying that steerage which the tail could not. The eagle, however, would seem to be an exception to this rule in some measure: it has *short legs* and a *short tail* also; and, we are inclined to think, cannot turn with that rapidity which we see so easily effected by some of the other feathered tribes: but it appears as if for ever on the wing, at an immense height, constantly sailing, as it were, in circles, without exertion: the writer has frequently watched them for hours together.

Birds seem wisely and curiously constructed to assist this aerial motion; in every part of their form they are active and buoyant, moulded for lightness and shaped for celerity. The lungs also of birds, as compared with the lungs of quadrupeds, contain in them a provision distinguishingly calculated for this same purpose of levitation; namely, a communication (not found in other animals) between the air vessels of the lungs, and the cavities of the body; so that by the intromission of air from one to another, at the will, as it should seem, of the animal, its body can be occasionally puffed out, and its tendency to descend in the air, or its specific gravity made less. The bodies of birds are blown up from their lungs (which no other animal bodies are) and thus rendered buoyant.

On the subject of the migration of birds, Bingley, in his "Animal Biography," observes—"The following is a table of the migration of several of the British birds, taken on the average of about twenty-

six years, from the observations of Mr. Markwick, inserted in the first and fourth volumes of the Linnean Transactions." Then follows the table, wherein the appearance of the quail in this country is stated to be the twentieth of August! that of the land-rail on the first of September!" Now, every person at all acquainted with rural affairs, knows full well, that both the quail and the land-rail appear in this country in spring, generally in the month of April; and that in fact for the purpose of breeding they must appear for the first time in spring, and not, as Bingley has stated it, at the latter end of the summer. Bingley's table is made up, for the most part, of similar absurdities. This is one striking fact, amongst a thousand others, of the caution necessary in forming an opinion of any thing advanced by writers who affect to treat a subject of which they are most profoundly ignorant; and for the purpose of making up a book, they merely copy the opinions or assertions of preceding scribblers, whose ignorance they thus continue to promulgate and preserve.

**MINNOW.** This little fish abounds in many of our small gravelly streams, where they keep in shoals; and when in right season, which only happens just after spawning, it is dappled, its sides inclining to a greenish watery sky colour, its belly white, and its back almost black, but these colours are not universal; the body is slender and smooth, the scales being extremely small; it seldom exceeds three inches in length; the lateral line is of a golden colour, the back flat and of a deep olive; the sides and belly vary greatly in different fish, as a few are of a rich crimson, others are bluish, and others white. The tail is forked, and marked near the base with a dusky spot. The minnow appears first in March, continues until Michaelmas, and then betakes himself to the mud, weed, roots, or wood in rivers, to secure himself from floods and fishes of prey. They are usually full of spawn all the summer, (for they breed often) and quickly arrive at their growth and perfection. Although so diminutive in size, the minnow may be compared, for the excellency of its taste, to many of the most famed fish. To the young sportsman, who has not possessed himself of the patience requisite to form the angler, the minnow yields plenty of amusement. They will, in hot weather, bite eagerly all day, and are frequently drawn out of the water from their adhering to the end of the worm, without being touched by the hook; the best way to catch them, is to have three or four very small hooks, baited with the least red-worm, or a piece of one, and a crow quill float; fish deeper than mid-water, or near the ground in shallow places, in eddies, and at the sides of small streams.

Minnows are very excellent baits for many fish, and when wanted in haste for that purpose, a small meshed casting-net will save much time and trouble, as enough for a day's diversion may be caught at a throw or two in shallow streams.

**MIRE-DRUM.** See BITTERN.

**MOLTEN GREASE,** called also **MORFOUNDER,** or **BODY FOUNDER.** This disorder is produced by too great, sudden, or powerful exertions, when a horse is not in proper condition: as in strong and severe hunting, long and speedy journeys, or hard driving in carriages, when the animal has been just taken from grass, loaded with impurities: just out of a dealer's possession, full of light flatulent food; or when naturally too full of flesh for violent exercise. In such cases, from the internal heat, increased circulation, and temporary inflammation, the fat seated upon the membranes in various parts of the body undergoes refraction and rapid solution, making distinct efforts for discharge by the different emunctories. The proportion nearest the vessels becomes absorbed, and there is produced some degree of fever; another part makes its appearance in the excrements; a third portion fixes upon the lungs, and obstructs respiration; to these a laxation of the intestinal contents succeeds; and, lastly, a looseness or scouring; so that in the present instance we plainly perceive the possibility of almost a complication of disorders originating in a single cause, and the foundation of that cause—indiscretion.

The symptoms are in different subjects, more or less violent, according to their state and condition at the time of attack;

varying in all, in proportion to the parts most affected by the original cause. Wherever the solution has proved most partial, the effect will become predominant; as, for instance, upon the bowels, lungs, or circulation of the blood by absorption. In the first, great pain attends the laxation or looseness; in the second, great difficulty of breathing from the expansion of the lungs may produce symptoms of inflammation there. And when the mass of blood is generally affected, and preternaturally loaded, fever must consequently ensue. These symptoms, as before observed, all vary in different subjects; but one is *pathognomonic* or *invariable* in all, which is the general incorporation of a greasy substance with the excrements, nearly similar to the separated particles of congealed oil in frosty weather; previous to the entire solution of the intestinal contents, and so long as the dung retains its usual form, the greasy hue appears only upon the surface, but as it advances in disease it becomes more intimately united.

So soon as ever these symptoms are perceived, proper methods should be taken to relieve nature from the threatened oppression, by such evacuations as the predominant circumstances direct; at any rate, let plentiful bleeding be the first step to reduce present, or prevent approaching, inflammation. If fever has not come on too rapidly, give, so soon as circumstances will permit, the following mild laxative drink:

Take of Senna, two ounces;

Boil it a few minutes in three quarters of a pint of water, with three drachms of ginger bruised; then strain and dissolve in the liquid,

Lenitive electuary, four ounces;

Soluble tartar, three ounces; add

Tincture of senna, six drachms;

Tincture of jalap, one oz. Mix.

But should the horse be strong and powerful (the disease being in its infancy), give without delay the following purging drink, repeating it in three or four days, if present appearances justify the practice.

Take of Senna, two ounces;

Infuse it in a pint of boiling water with

Salt of tartar, two drachms; add

Vitriolated magnesia (Glauber's salt), four ounces;

Cream of tartar, two or three drachms

Dissolve and make the drink.

If the patient be greatly depressed, with palpable fever, disquietude, loss of appetite, and internal painful sensations, make use of the following clyster, which may be easily prepared.

Take of Water gruel, two quarts;

Coarse sugar, half a pound;

Common salt, a handful;

Olive oil, four ounces.

Mix and inject tolerably warm.

To attenuate the blood, relieve the lungs, and take off the load from the circulation, as well as to mitigate all symptoms of fever (if such there are), adopt a cooling plan of treatment, with the assistance of bran water or pectoral decoction, especially if the lungs are much oppressed, or the approach of inflammation apprehended. The appetite must also be attended to, and solicited in every stage of the disease by comfortable mashes. The advice of a veterinarian is indispensable.

**MOON-BLINDNESS.** A disorder in the eyes of a horse, so denominated from its having been thought to increase or decrease, according to the course of the moon.

This generally happens when a horse is turned five, coming six, at which time one eye becomes clouded, the eye-lids being swelled, and very often shut up; and a thin water generally runs from the diseased eye down the cheek, so sharp as sometimes to excoriate the skin. The veins of the temple, under the eye, and along the nose, are also turgid and full of blood, though sometimes it happens that the eye discharges but little.

Moon-blindness scarcely ever admits of a cure. It generally takes place while the horse is young, and sometimes has been attributed to the pain in cutting the teeth.

The inflammation in this disorder comes and goes till the cataract is confirmed, and then all pain and running disappear, and the horse becomes totally blind, which is generally in about two years.

There is another kind of moon-blindness, which is also the forerunner of cataracts, where no weeping of the eye attends. The eye is never shut up or closed here, but will now and then look thick and troubled; at which time the horse sees nothing distinctly. When the eyes appear sunk and perishing, the cataracts are longer in forming, and it is not unusual in this case for one eye to escape.

These cases generally end in blindness of one if not both eyes: the most promis-

ing signs of recovery are, when the attacks come less often, and their continuance grows shorter; and that they leave the cornea clear and transparent, and the globe plump and full.

**MORTIFICATION.** This state, in a physical sense, with either man or beast, is the total cessation of vital heat in any part of the body or extremities, which then becomes insensible, and followed by putrefaction. When a mortification arises from some external injury done to the part, it is not preceded by a gangrene, but is produced by an absolute stagnation of the blood and juices, and all the injured parts become insensible and putrid at the same time, without any previous inflammation. A mortification arising from some internal cause, or a deficiency of natural heat, comes on in the same manner, but is more tardy in its progress, although it exhibits similar appearances; but the nature of the disease may be readily discovered. When an external injury is the cause, if an incision is made early in the diseased part, it will be found insensible, and nothing but extravasated blood will be discharged. In all cases of mortification, the disease, with its concomitant symptoms, proceed with a rapidity that sets every medical interposition and exertion at defiance.

Dr. Kirkland well observes, that it is very proper to distinguish betwixt local gangrenes inclining to spread, and gangrenes from a bad habit; on which he observes as follows:—"When the mortification arises simply from injury done to the limb, it is not preceded by a gangrene, but comes on in consequence of an absolute stagnation of the blood and juices alone; and accordingly the skin, and all the injured parts, become dead and putrid at the same time, without any previous emphysema. A mortification arising indeed from a weakness and deficiency of native heat comes on in the same manner, only more gradual, with the same appearances; but the state of the patient will easily lead to the nature of the disease. When external injury is the cause, if an incision is early made, the part is insensible, and no other than extravasated blood is discharged. In this kind of mortification the countenance is serene, nor does any other fever supervene, but such as is common to contused wounds; and, unless the affected part is very near the body, the disease slowly extends itself by the acrid fluids corroding the neighbouring parts in the manner of a caustic, till

matter enough is absorbed to contaminate the whole mass of blood. But a stop may be always put to local sphacelus; for a mortification rarely arises merely from the injury done to the part, which would not give way to proper management.

When a mortification arises from an internal cause, that is, from a gangrenous disposition of the juices soon after the injury is received, whether a large wound is made by external violence, or a small wound by protusion of a broken bone, the lymph which stagnates about the wound, immediately inflames and corrodes the vessels which contain it, when air-bubbles in the adipose and other membranes are instantly set at liberty; which air-bubbles, by increasing the inflammation, are increased, and extended immediately upon the smallest degree of obstruction taking place all over the limb, &c. an emphysema often first discovering the tragedy that is acting under the skin, not yet apparently diseased. A fever at this time frequently comes on, accompanied with a delirium, great dejection of spirits, and often a particular wildness in the looks; the pulse is either quick, low, weak, and fluttering, or quick, unequal and hard, and the scene is frequently closed with a rapidity that will not admit of assistance. If an incision is made into the affected part, when the air-bubbles are first formed, it is sensible, and blood is discharged from the arteries, in a florid state, as free as usual: the adipose membrane is of a darkish yellow colour, and the muscles only appear browner than common. Afterwards the skin becomes inflated, and the muscles, not yet having lost their shape, frequently force themselves out immediately upon making an incision, with a large discharge of wind, and a quantity of frothy matter: the blood in the vessels is now turned to a black coagulated mass; the adipose membrane, and the membranes in the interstices of the muscles and fibres, and the muscles themselves, putrify; and, lastly, the skin also becomes livid and putrid: from all which, it is evident that a gangrene brings on a sphacelus, while the blood is yet circulating in the vessels."

The usual signs of a present gangrene are, the sudden removal of inflammation (when inflammation attends); the lessened sensation of the part, for the skin does not so speedily mortify as the cellular membrane; hence, till the skin is destroyed, there is a little feeling. A pale,

cineritious, dark, livid or black colour, which is always worse as it recedes from the pale to the black. Softness and flaccidity of the parts, so as to retain the impression made by the finger: pustules or blisters, full of lymphatic, yellowish, or reddish ichor; this is generally accounted the pathognomonic sign of a gangrene on the external part of the body.—When a gangrene is induced by cold, an itching, and a violent sense of puncture, together with intense redness, soon succeeded by blackness, indicate mortification: the cold produces first a paleness, which is succeeded by redness, accompanied by a troublesome pungent pain, or an uneasy itching. Then the redness is increased to a purple colour, and afterwards the part becomes black.

The remote cause is, the reduction of the vital heat in the part to a certain degree below that which health requires.

The immediate causes are, violent inflammation, which, by the heat attending, so distends the cellular membrane as to compress the vessels, stop the circulation in the adjacent parts, and destroy the vital action there. The acrimony of the juices, by rupturing the vessels in an inflamed part, occasions an extravasation of blood, which, putrefying, produces a mortification. A contusion or wound of the spinal marrow, by preventing any further influx of the vital heat to the parts below where the injury is received, causes a mortification there. External compression, intense cold, compression from tumours internally, poisons, &c. produce the same effect.

These doctrines obtain no less in quadrupeds than in men, though the evidence in proof of them cannot, of course, be so complete.

The indications of cure are, to confirm the strength, or to raise and maintain the vital heat a little above the natural healthy degree,—to prevent the absorption of the putrid matter into the veins. Against the progress of gangrene in the human subject, it is found, that cinchona (the Peruvian bark) is the only known specific; but yet its use is not to be indiscriminately admitted of in every case. In habits that are lax and feeble, no objections can occur to prohibit it; but in inflammatory habits, nitre, or mineral acids, should accompany it if given, and great caution is necessary before it is directed. If the inflammation is considerable, the mineral acids are more proper even than the bark. If the pulse be strong, large,

and hard, and the extremities of the body are warm, the urine red and high coloured, the circulation is sufficiently strong, so need not be increased; but if the pulse be weak, and the symptoms indicate a defective vital heat, cordials will be necessary.

Mr. Pott observes, with his usual sagacity, that a mortification proceeds from a circulation that is too rapid, or too languid; that, in the first case, bleeding and diluters, and in the second, cordials and invigorating medicines, must be prescribed. When a mortification is from an internal cause, there is usually great pain, and opium is directed to be freely used. This should be done whether the cause is internal or external; in these cases, opium is the greatest cordial known.

How far these remedies may be expected to succeed in the horse and other animals is yet to be ascertained. The power of opium on the horse has been denied, and even that of bark called in question.—May not the metallic salts be employed for the latter? It is to be observed, indeed, that though mortification very commonly terminates the diseases and lives of brutes, it is seldom thought worth while to make any attempts to arrest its progress. Perhaps it is because that progress is usually very rapid; perhaps from a well-founded suspicion of the insufficiency of our remedies.

**MOULTING.** When birds change their feathers they are said to moult.

**MOULTING.** This term is very appropriately used by Mr. Clark, of Edinburgh, to denote that natural process by which horses and other quadrupeds cast their hair. We shall follow that judicious writer in our remarks on this subject.

Horses, towards the end of autumn and beginning of winter, exhibit signs of some particular change about to take place in their constitutions; and this, at the same time, is attended with a degree of faintness or weakness mostly observed at that season. This, our author supposes, may arise from a variety of causes combined together; but the principal one, he apprehends, may proceed from that of moulting; for, although horses in general do not cast their hair at this season as they do in the spring, yet, as a considerable change takes place in its thickness and length at this period, it may properly be called their moulting season. “Horses of all colours, (says Buffon) like most animals covered with hair, moult or cast their hair every year, commonly in the spring, and sometimes in the autumn.

As they are then weaker than at any other period, they require more care, and should be more plentifully fed." The diseases that prevail at this period, in horses, are noticed by Mr. Clark in the following way:—

"As those horses (says he) that are kept in warm stables, and well fed through the winter, are hearty and vigorous in the spring, when the season is gradually turning milder and warmer, their moulting at this season is not attended with that faintness, &c. to which they are liable on their moulting towards the end of autumn." The reason of this the author attributes to the food of horses, which in the spring is dry, producing richer and better nourishment; also to the change of the season which then takes place, and which is more agreeable to their constitutions. Towards the end of autumn, he observes, it is very different with the generality of horses, and especially with those that have been fed with new hay, new grain, or late grass, and, at the same time, have undergone severe labour. Such kind of food, abounding too much with watery juices, produces less nourishment, and causes a general laxity of the muscular fibres of the whole body; and hence arises the increased languor and weakness so generally prevalent during the time of moulting.

It is observed (continues the author) that horses kept in warm stables, and well fed, moult early in the spring; those that run abroad at grass moult much later. But if the former should be exposed to cold winds or rain for any length of time together, by being turned out to pasture, or otherwise exposed to cold weather, after they have once cast their winter coat, it appears that their hair will then grow thicker and longer, the same as it does in the beginning of winter, and continue so till the season grows milder, or that they are kept in warm stables: in this case, such horses may be said to have moulted twice in the spring."

The cold and moisture of the weather, at this season, in Britain, are likewise adduced as a farther cause, contributing to increase this indisposition by occasioning a constriction of the pores of the skin; for, at this period, the hair of the generality of horses staves, whilst, at the same time, the skin is commonly dry and hard, or the animal is what is called hide-bound. They sweat, indeed, most profusely when put to hard work, merely through weakness and relaxation; yet that natural in-

sensible perspiration which produces a shining and smooth appearance on: he coat, seems to be almost suspended. Under such circumstances, they are disposed, upon any irregular management, to fall into diseases of various kinds. From the general constriction of their pores, that fluid which ought to pass off by insensible perspiration is retained; hence, the quantity of fluids in the vessels being increased, whilst the muscular fibres through the whole system are relaxed, a deranged state of the circulation takes place, and hence proceed swellings of the legs, greasy heels, &c. so common at this season of the year.

On the other hand, horses that have had the early spring grass, and are afterwards kept on hay, with a good allowance of grain, and daily accustomed to moderate exercise, suffer no material injury from moulting in the autumn, further than their being more liable to catch cold at this time, from the alternate changes they are exposed to, before their coats of hair have grown sufficiently thick to resist the cold.

Robust horses, at grass through the summer, if exposed to active exercise, are liable to many diseases about the time of moulting, as the interval from the time they are taken from grass, and the moulting, is too short to admit of their bodies being prepared to perform these exercises with safety to themselves. Hence they fall into that languor, &c. peculiar to this season; and, if left in the stable too much at rest, their gross habit of body disposes them to fever, disorders of the lungs, swelling of the legs and glands about the throat and jaws, and running sores, &c. nor are they able to undergo common exercise, without being jaded.

Horses that run at grass through the summer and autumn, are still in a worse situation. These are not only more liable to the foregoing diseases, from their very lax habit of body, but are less fit for active exercises of any kind, and require a longer time to be brought into a proper state. This period, in particular, proves critical with them, and, indeed, they generally fall victims to disease if too much worked.

It happens too, that, in the situation above mentioned, the means required to render horses fit for active exercises, and to carry off the appearance of swelling of the legs, &c. are evacuations of every kind, such as bleeding, purging diuretics, &c. At the same time, these methods

are sometimes hurried on with a degree of haste that would even affect a sound horse, of the most hardy habit of body, at any season, and reduce him to great weakness. The moulting now comes on, which still adds to it. In these circumstances, the constitution receives too great a shock to be resisted; and hence many horses fall a sacrifice to this treatment, or, if they survive, they are attacked with some chronic disorder, which renders them useless to their owners.

“The end of autumn (says Mr. Clark) likewise proves very severe on those horses whose flesh and strength are exhausted from continued hard labour, or violent exercise, as posting, &c. through the summer and autumn; when the moulting comes on in this low, spiritless state of body, it carries off great numbers of them, that by proper care in moderating their labour, together with good nursing, and feeding them with rich boiled food at this time, their lives might be preserved. Such soft nourishing food becomes the more necessary for horses of this description at this particular period, in order to support them under the moulting, as the serous or watery parts of their fluids having been drained off by the violent perspiration they were exposed to, their muscular fibres are then too rigid, and the blood too thick, for circulating so freely as it ought to do through the fine capillary vessels; hence they are disposed to fall into those disorders which proceed from this cause.

Many of those horses that are thought to be worn out from posting, &c. at the end of autumn, when they come to be fed with boiled food, or with potatoes or carrots, and continued so through the winter, recover surprisingly. This last-mentioned food recovers their flesh; it renews their fluids in general, and promotes all the natural secretions: it operates on them nearly in the same manner as the spring grass; it purges them gently on the first use of it, and corrects the whole habit. On changing their food to that which is hard and dry, as oats and beans, and increasing their exercise gradually towards the spring, they soon become fit for the most active exercises, without any previous preparation from medicine, &c.

This season likewise proves destructive to aged horses: when the green food is exhausted, they are then obliged to feed on hard dry food; in some, the digestive powers may not only be weaker, but the teeth, at the same time, may be defective,

in not breaking down the hard food so minutely as it ought to be, in order to render it fit for digestion, and the nourishment of the body.

After illustrating this by a case in point, Mr. Clark proceeds to observe, that “As the disorders which commonly prevail at this time amongst horses, proceed in a great measure from catching cold, together with the sickness attending the moulting, horses are differently affected, according to the circumstances of habit of body, and the treatment they may be exposed to; some are affected with colds in the head, attended with inflammation and swelling of the glands about the throat and jaws, which too frequently, from want of proper care, terminate in the glanders; hence this disorder is frequent at this season. Some horses are affected with coughs, and other disorders of the lungs. Rheumatism is likewise common in different parts of the body, particularly in the neck, which is called the chords. Epidemical diseases frequently originate at this period, and continue with more or less violence through the winter, and sometimes till towards the spring. Fever is likewise common, together with a variety of other complaints, which would be tedious to mention. All these disorders are forwarded from the above circumstances, together with horses breathing a heated foul air in their stables, and their bodies exposed suddenly to the chillness of the weather, before their coats of hair have grown sufficiently thick to resist the cold, &c. for it is observed in those horses which run abroad in the fields day and night, that they moult much sooner in the season; by which means they are sufficiently guarded against the severity of the weather when it becomes cold and damp; neither is it observed that they are so liable to be affected with those epidemical diseases which prevail amongst horses that are kept in too warm stables. This sickly disposition amongst them continues with more or less violence till such time as the weather turns more favourable and dry, or that the frost sets in. It commonly commences, if the weather is moist, cold, and damp, about the middle of October, and continues till towards the middle of December: after which, if it is favourable, horses generally become more lively and vigorous, and acquire their usual spirit, and healthy appearance,” &c.

From what has been said, it may be observed, that as horses are generally

more weakly at the time of moulting towards the end of autumn than at any other season, their labour, when circumstances will admit, should be moderate. " Their feeding should be increased in order to strengthen and support them during this period. It ought likewise to be of the very best quality, as old hay, old grain, that is, of the preceding year's growth; and if the grain that is given them was broken down in a mill, it would prove more nourishing than in any other way it could be given them. New hay, or new grain of the same year's produce, ought to be avoided, as it is extremely hurtful to horses, that must undergo severe labour, or active exercises, of which we have formerly taken notice. Good rubbing and frequent dressing are likewise of great benefit.

All evacuations, such as bleeding, purging, rowels, &c. ought to be administered with caution, as such prescriptions contribute greatly to increase that natural weakness, &c. formerly mentioned, which prevails in the constitution of horses at this period. At the same time it is to be understood, that horses are not by any means to stand too much at rest in the stable. Fresh air, with moderate exercise, when the weather will permit, being absolutely necessary to promote their health; neither is the proper use of the above prescriptions to be neglected when they are thought necessary, and prescribed with judgment. All the precautions formerly mentioned, with respect to their stables, ought to be attended to, that they are kept clean, well ventilated, and yet moderately warm. Body-cloths, however necessary they may be thought for keeping their coats of hair fine, smooth, and clean in the stable, ought to be dispensed with. As horses cannot with propriety be ridden with them, they must therefore be stripped the moment they are to go abroad, even although they should happen to be in a strong perspiration at the time; by which means they are liable to catch cold, &c. And surely the health of a horse is of much more consideration to his proprietor than the looks or appearance of his coat of hair, especially when it is considered, that good rubbing and frequent dressing will produce the same effect on the appearance of the hair. At the same time that this operation will in a great measure prevent the consequences above mentioned, of rendering horses so very liable to catch cold."

**MOUTH.** The external parts of the mouth are the lips, the beard, the end of the nose, being a continuation of the upper lip, and the chin. The internal parts are the bars, the tongue, the channel, the palate, and the teeth.

The mouth of a horse should be moderate in size; for when it is too wide, we find much difficulty to bit a horse, so that he may not "swallow it," as the term is: and, if he has a little mouth, it will be difficult to get the mouth of the bit rightly fixed in it.

To have a good mouth, he should have a well raised neck; and if it be somewhat large and thick, it ought to be at least well turned. But if his jaw-bones be too close, and he have also a short and thick neck, so that he cannot place his head right, his having a good mouth will avail but little.

The compliance and obedience of a horse is owing, partly, to the tender or quick sense of his mouth, which makes him afraid of being hurt by the bit; and partly by his natural disposition and inclination to obey. The mouth is called sensible, fine, tender, light, &c. Some horses have so fine a mouth, that they stop if the horseman does but bend his body behind, and raise his hand, without staying for the pull or check of the bridle.

1. A mouth is said to be *fixed* and certain, when a horse does not chack or beat upon the hand.

2. A *false* mouth, is a mouth that is not at all sensible, though the parts look well, and are all well formed.

3. A mouth of a full *appui*, or rest upon the hand, is one that has not the tender nice sense of some fine mouths, but nevertheless has a fixed and certain rest, and suffers a hand that is a little hard, without chacking or beating upon the hand, without bearing down or resisting the bit, insomuch that he will bear a jerk of the bridle without being much moved.

For the army, provide a horse with a mouth that bears full rest upon the hand; for, if you take one of a tender mouth, and another horse run against him in a fight, he will be apt to rise upon his hind-feet, which a horse of a hard mouth would not do.

4. A mouth that bears more than a full rest upon the hand, implies a horse that does not obey but with great difficulty. You will not readily stop such a horse, for his mouth is above a full *appui* upon the hand.

**MULE.** The mule is that well-known cross-bred animal, generated between an ass and a mare. Some are, but very rarely, produced by the horse with a she ass; but they are smaller, weaker, and of less utility, consequently not bred with design. The mule, when well descended, and well fed, is adequate to a variety of services, and will, if taken the same care of when young, nearly reach the size of a moderate horse. Many have measured fifteen hands high and upwards; they are exceedingly strong and sure-footed, which qualities render them very valuable in the different parts of Europe where the countries are mountainous, and the roads stony, as they will travel with the greatest ease and security where a horse would be very likely to break his neck. They are likewise exceedingly useful in harness, and will draw immense weights for long journies without displaying the least fatigue.

The mules bred in Spain, with a proper attention to their intentional use, whether for travelling or show, are bred between very large he-asses and Spanish mares; these are exceedingly tall, stately, and their colour inclining to black. A still larger kind are, however, produced by these asses out of Flanders mares, some of which have been known to reach seven-

teen hands high, and of equal apparent strength to our common carriage horses; but they are much stronger than horses of their own size, will bear infinitely greater hardships, and are kept at a much less expense; as well as an additional recommendation, that they are not so subject to diseases, which is a material consideration to the justification of their more general use. They are found equally fit for the saddle, as for the more laborious employments of draft and agriculture.

What few mules are produced in this kingdom, at least the major part, may be probably bred more from chance than design, by the common intermixture and unrestrained association of asses with mares, upon the large wastes and commons in various parts of the country, where they are frequently seen in the act of propagation. Of mules, it is to be observed, that, although such intermediate animal is produced between the two which generate the third, there the prolific property ceases, and propagation goes no farther. Thus it is with a part of the feathered creation; it is known by those who breed, that a cock goldfinch, or a linnet, will pair with a hen canary, and produce young; but in that offspring the power of procreation entirely ceases, and they are therefore termed mules.

**MULLET, THE,** is found in great plenty on several of our sandy coasts, and in particular haunts those small bays that have influxes of fresh water; they are very cunning, and when surrounded with a net, the whole shoal frequently escapes by leaping over it; for when one takes the lead, the others are sure to follow.

They come in great shoals into the rivers with the tide during the summer, and keep rooting like hogs in the sand or mud, leaving their traces in form of large round holes; but return back when the water ebbs, never stopping in the rivers. They are something like the dace in shape, yet much thicker; the head is almost square and flat on the top; the nose blunt, lips thick; they have no teeth, only the upper lip is a little rough, as is also the tongue; between the eyes and mouth is a callosity: the pupil of the eye is black, encircled with a small silvery line; the colour of the back is dusky, varied with blue and green; the sides silvery, marked with broad dusky parallel lines, reaching from head to tail, which is much forked; the scales are large and deciduous, and are also upon the covers of the gills and head, and extend as far as the nostrils. The largest are nearly half a yard long, and the flesh is excellent.

The same artificial flies as for trout are to be used, and they are to be angled for as the tide comes in, before the water gets thick, with those in preference to any other bait; when the water is discoloured, use a small red-worm or gentles, and fish within two feet of the bot-

bottom with strong tackle, as the mullet when hooked will struggle vigorously.

**MUTE.** A dog is said to run mute, when he pursues his game by the scent without giving tongue. Some hounds are too free with their tongue, they open perhaps without any scent, and are called *babblers*; so hounds are said to be mute when they run with the scent without giving tongue.

**MUZZLE.** Muzzles are of two sorts; the one called a dressing, the other a setting, muzzle. The first is of the same form as the last, but of different construction, having a few straps crossing each other transversely, and so united as to be about nine inches in depth, and of a shape to cover the nose of the horse so high; to which are annexed two straps; one of which passes up the cheek on each side,

and buckles at the top of the head behind the ears; the use of this is to dress such horses in as are disposed to vice with the teeth, as well to prevent the manger from injury, as the groom from danger. The other is in little use, except in training stables; having a number of round holes punched in every part of it, for the free admission of air, and is brought into use on those nights preceding a horse's running engagement on the following day; as well as before taking a sweat, or running a trial. It is called a setting-muzzle, because, when put on, the horse is said "to be set" (that is, to fast); and the intent is to prevent his consuming the litter, or obtaining more food than what the training groom judges to be expedient.

## N

**NAG.** In common country acceptation, implies a riding horse or roadster, in contradistinction to a carriage or cart-horse.

**NAIL.** A small flat pin of iron, by means of which the farrier fastens a horse's shoe to his foot. Mr. Moorcroft, in his "Account of the various methods of shoeing horses," observes, that eight nails for each shoe are enough for saddle and light draught horses; but for such as are employed for heavy draught, ten are required. A smaller number, it is found, do not hold the shoe sufficiently fast; and a greater number, by acting like so many wedges, weaken the hoof, and rather dispose the crust to break off, than give additional security.

The manner of disposing the nails, says he, has differed considerably at different times. Some writers have directed four to be placed on each side of the foot, and the hindmost near the heel; leaving between the two rows of nails, a considerable space of the fore-part of the foot without any.

The nails thus placed, certainly confined the foot at the sides and heels, left the toe at liberty, and assisted materially the effect of the sloping surface of the common shoe, in altering the form of the foot from a nearly round, to a lengthened figure.

Latterly, it has been strongly recommended, to place the nails principally at the fore part of the foot, in order to pre-

vent the heels from being confined. And certainly this is a wiser practice than the former; but as the foot should rest on the shoe in the whole extent of the crust, it may be thought, that the best way of connecting them in every part alike, would be that of placing the nails at equal distances from each other, in the whole round of the shoe.

However, the objection to this is, that when the foot strikes the ground with considerable force, the back part of it becomes a little broader than when it is in the air, or when the foot is at rest. This spreading is not considerable, nor does it extend far along the sides of the foot, but it is sufficient to act upon the hindmost nails when near the heels; hence arises the necessity for there being a greater distance between the last nail and the heel of the shoe, than between any two nails. Accordingly it may be laid down as a general rule, that the last nail should not be nearer the heel, than from two inches to an inch and a half.

Such a distance has been found sufficient to prevent the heels being confined; and not sufficiently great to allow the shoe to spring, and loosen the last nails, as frequently happens when they are farther distant from the heel.

All the nails should be at equal distances from each other, except the two in front, which should be a little wider apart than the rest: this, however, is not a matter of essential consequence; but it is

of importance that there should not be any nail in the middle of the toe. For, generally, the action of the foot on the ground has a direct tendency to push the shoe, as it were, backwards along the foot; and it sometimes happens that the shoe is actually thus displaced; in which case it necessarily follows, that the nail in the middle of the toe must be driven immediately against the sensible parts behind it; whilst the rest of the nails in a great measure follow the line of the crust, and thus avoid doing mischief to the parts within.

The nail-holes on the upper surface of the shoe should come through the seat, close to the edge of the bevel, that the nails may have a proper and equal hold on every part of the crust, which will be shewn by the clenched ends being each equally distant from the shoe.

As the nail-hole is always made with a taper and square-pointed punch, a nail with a head of the same form will fit it better than one of any other shape.

The most general practice to prevent slipping in frosty weather is called roughing or sharpening; which is merely making two caulking to each shoe. This is liable to the objection before stated, of throwing the weight too much on the toe, and of the inside caulking sometimes wounding the opposite leg. And it is farther objectionable, because the caulking soon wear down; as, in order that they may take the necessary hold on the ground, they are made sharp and thin. They therefore require being frequently renewed; and hence it generally happens, that a horse which is much worked in frosty weather, has his feet more broken and injured than in the common wear of many months.

To prevent the necessity of frequent removes, several expedients have been put in practice. Sometimes a few nails, of a larger size than the rest, have been so put in, that the heads stood considerably beyond the level of the shoe; but when these did not break off, as was often the case, they soon wore down.

At other times, nails with large heads, tapering to a point, were screwed into the web of the shoe. Of these, one was usually placed at the toe, and one at each heel. And by this contrivance of the screw, it was imagined, that the nails might be easily replaced when worn out. They are apt, however, to break off at the neck, and are too expensive for common use.

There is, notwithstanding, another plan,

which, as far as it has been tried, justifies the author in recommending it.

This consists in having nails with a lozenge head, or what may be called a double countersink, terminating in an edge, instead of coming to a point. This greater breadth of surface, prevents its being rubbed away as fast as a point; the thickness of the middle gives it strength; and the regular taper to the shank, causes it to apply exactly to the sides of the hole in the shoe, by which it is equally supported, and prevented from bending or breaking. There should be four nails to every shoe; that is to say, two in the fore-part, and one at each heel.

The heads of these nails must be struck in tools, or dies; the four holes in the shoe must be made to correspond with the neck of the nail; and when the nail is driven, the workman must cover the head with a tool, which will receive its upper part, and prevent its being injured by the hammer.

These nails are, in effect, so many caulking, with the advantages of allowing a more level tread; of being easily replaced, by putting new nails in the old holes; and, by being at a distance from the heel of the shoe, they are not so likely to hurt the opposite leg.

NARES. The nostrils, particularly applied to birds.

NARROW HEELS. See HEELS, NARROW.

NAVICULAR DISEASE. See NEUROTOMY.

NEAR-SIDE. The near-side of a horse is the left-side, and of course the side on which the rider mounts. The right-side of the horse is always called the off-side. It is the invariable custom to say, that horse is lame of the "near-leg before;" the other, is evidently defective in the "off-leg behind."

NECK. That part of the animal by which the head becomes connected with the shoulders. This is long in all quadrupeds, in proportion to the length of their legs, or the distance from which they have to reach their food from the ground. The neck of a horse should be lean, with but little flesh upon it; and to be well shaped, it should, at its going from the withers, rise with a slope upwards, diminishing by degrees towards the head. In mares, it is a good quality to have their necks somewhat strong, and covered with flesh, because their necks are generally too fine and slender.

Deer-necks, ewe-necks, or cock-throp-

pled, are those, in which the flesh that should be next the mane, is set quite below, and next the throat, which renders the neck ill-shaped and ugly.

Mr. St. Bel, describing the defect in the proportion of the neck of the celebrated horse Eclipse, says,—“The faults of the neck are in general the consequences of the defects of the head; for it is an uncommon thing to see a short head with a long neck, as, on the contrary, to see a long head with a short neck.

If the neck is too short, the fault will be an addition to that of a too short head. The case will be the same if the neck is too long; for the head will naturally weigh heavier, in proportion as it is removed from the fulcrum or rest of the lever, supposing it to be well proportioned. Its length should be nearly one third of the height of the body, measuring from the withers to the ground. The neck will be well proportioned if it measures one head and a half from the nape to the withers.”

**NEEDLE-WORMS** are small white worms with a sharp-pointed head, having their seat in the rectum of a horse, from whence they are frequently discharged with the dung, but are difficult to dislodge and extirpate entirely. By their unceasing action, (twirling and twisting in the dung when expelled,) it is natural to conceive, how very much they irritate and distress an animal; of this there needs no greater proof, than the excrements frequently and suddenly coming away in a liquified state, as if the horse was under a course of physic. They are sometimes not only reduced, but eradicated, by antimonials; but as this is not always to be relied on, mercurial physic is justified upon the broad basis of experience, as the only infallible mode of extirpation.

**NEIGHING.** The peculiarities of the voice in different quadrupeds appear to consist principally in the number and form of the laryngeal sacs. There are usually three of these, one of which appears under the vault formed by the anterior boundary of the thyroid cartilage, having its aperture near the root of the epiglottis. The other two are oblong sinuses contained between the lateral parietes of the glottis and the thyroid cartilage, and are covered in a great measure by the arytenoidei muscles. In the horse (says Blaine) these lateral sacs are very long and wide, and are not unlike the usual ventricles of the glottis. The aper-

ture of the outer cavity is very large in the horse: in the ass the opening into each of the three sacs is a small hole, and the anterior sac forms a bag-like cavity. In the mule these organs differ, but their anatomical formation is in general blended between the horse and ass. The various sounds emitted by animals are named arbitrarily, without reference to the noise heard: thus we say the horse neighs, and the ass brays. Neighing appears produced by expirations, as are most of the tones of voice from the horse. The vibrations produced by the resonance of different sized cavities, assisted by the tremors of the cartilages of the nostrils, produce the compounded sounds which are emitted. *Knuckering*, as it is termed, is only a lesser neigh, with shorter, deeper, and less forcible tones, and expresses affection and joy. The horse has one acute sound, produced by the act of inspiration, which usually expresses either play or lust; but in most other instances, sound in the horse is produced from expirations; nor does it appear that the tongue or teeth are much concerned in the modulations of his voice; but in dogs they are very much so. In the ass, the principal sounds are *braying*, and perhaps he differs in no respect so much from the horse as in the sounds he produces; and this is another very strong proof, that an ass is not a horse degenerated, as has been by some supposed. Braying appears to be produced through the mouth by a convulsive displacement of the velum palati, assisted by the vibrations occasioned by the extent of the laryngeal sacs, and by their being so much separated from the cavity of the larynx. It is effected by alternate inspirations and expirations; the inspirations forming half tones, and the lengthened notes being formed of expirations.

Neighing is an exclamatory sensation by which the horse evinces either anxiety, suspense, or pleasure; but the passion he feels is expressed with much more force and energy in the two first, than in the latter, which is ejaculated with low and vibrative sounds, too expressive to be mistaken by even the inexperienced naturalist, or least attentive observer. Being separated from a companion with whom he has been accustomed to stand in the same stable, and to accompany each other abroad, his inquiries are loud and incessant upon the road or in the field; and if made upon a race course, amidst a thousand horses, they are so completely masters of their own language, that they can

instantly distinguish the exclamation of each other from the innumerable neighings of all the rest. Finding themselves answered, at whatever distance, they display their eagerness to get together; and as they approach each other, the pleasure becomes perceptible in the way before described, and by the experienced sportsman so perfectly understood.

**NETS FOR FISHING.** Of these there are great varieties; and almost every individual believes he has a peculiar plan of forming them superior to his neighbour: no set of men are more bigotted to their own opinions upon this subject than the London net-makers, some of whom, however neat their work, and apparently well disposed for the intended purpose, are so far from being competent judges, as scarcely ever to have seen many of the different kinds of net they deal in, set in water during their lives; it is not extremely probable that, under such disadvantages, they can know more than their customer's order tells them, which generally consists in desiring a net such a number of yards long, and so many feet in depth; respecting the hanging of the net, both parties are usually silent, and perhaps from the same cause. As a practical net-fisher, the compiler (than whom few men have seen, or in the water assisted more) ventures to give a few hints, which his brother sportsmen may not find unworthy of trial.

In the making a drag-net, the size of the mesh should never be less than one inch and a quarter; there should be an extent of three times in length, and twice in depth, of the plain-net, before it is hung upon the cork, and lead lines, (that is, if the drag is meant to be twenty yards long, and twelve feet deep, there must be sixty yards of net in length, and twenty-four feet in depth, for a sheet drag; if made with a cod, it must be let in with great care as to the widenings, so that in fishing it keeps a proper open centre). As drag-nets are usually hung, any one who is in the water when they are used, will feel, when the lines are hauled, the lead line above the calf of his leg, and frequently above his knee, and that continued to very near the bosom of the net. There is no occasion to remark upon the chance of success such an implement affords.

Always use two, if not three, flews with the drag; one or two flews can then be kept forward, for the drag to force to; and in fishing every hole, back the drag

with a flew, that is after the drag approaches close to the first flew, of course that will be pulled on one or other side of the river; if any fish are in it they should be taken out, and so soon as the drag-net has passed, let the flew be drawn back into its former station; the fish that are disturbed by the drag (from the deficient manner in which their lead lines have been shewn to keep a regular sweep at the bottom) soon perceive an opening to escape beneath it, and in striking to their old harbours, run headlong into the back flew; the discolouring of the water from the trampling of the people in, together with the motion of some part of the drag upon the mud, all contribute to the success of this expedient, by which the best fish will always be captured.

A drag-net should always be used up the stream; however low the water in a river may be drained for the convenience of those fishing in it, there will still be a current sufficient to preserve the water clear enough for stumps and hangs of various descriptions to be avoided; besides, the drain of the water keeps the meshes of the net extended, and enables it to fish with every advantage: on the contrary, when drawing down the stream, the mudding of the water progressively prevents the discovery of stubs, &c. that would injure the net, and aids the escape of the fish, and moreover drives the net into folds, which the leaves of the weeds turning the same way not a little assist.

*Flews* may be described as of two kinds; the one for drawing, the other to be placed either as a stop to a drag-net, or to be set and left quietly standing in a pond or river to intercept the fish. Those for drawing should be made of stouter materials, and the lint of all should be silk: the expence is greater at first; but the compiler has had silk flews of both sorts where the lint has outlasted three sets of walling, and still remained perfectly good; it must however be understood that great care was observed in the washing and drying his nets, for silk has no peculiar power any more than hemp, to defend itself against the heat, which a few hours will generate, when thrown full of mud and weeds, and both, by such slovenly inattention, are as quickly spoiled: yet carefully managed, a silk net will endure to the utmost wishes of the proprietor; and such is the quality of silk when wet, that the fish which touches it is sure to be entangled, the texture is so pliant, that a fish is enveloped before

being sensible of it, and the more he struggles the faster he is confined.

For a dragging flew, the lint, two inches and a quarter mesh, seventy meshes deep, and fifty-two yards in length, (to be hung twenty yards long, and eight feet deep;) it will take four pounds and a half of silk.

For a setting flew, of a similar mesh, and ninety deep, with the same length of lint, and depth of hanging, five pounds and a quarter of silk; from these may be calculated any larger or smaller size. Never tan or colour flews; it renders them easier to be discerned by the fish.

The walls or trammels of flews should be at least eighteen inches square (but two feet is preferable;) those of nine or twelve inches, hung diamond fashion, are only calculated to receive a fish that strikes point blank; it is impossible for a good sized fish to get in sideways (whereby they are more entangled than by touching the flew in any other direction,) besides these small wallings render a net more cumbersome, and are for the most part useless. Flews should be very lightly leaded, the floats or corks nicely adjusted, and both leads and corks of a length and size that will prevent their getting through the meshes of the lint in any direction, and entangling it. Where the fish run very large, the mesh of the lint may be extended, always recollecting that in thread nets the materials for the lint must be three twisted, and cannot be too strong or too fine.

In carp fishing, drawing with flews is the most killing mode yet devised; they slide so lightly over the mud, and hamper the fish in their progress through the water, which the drag-net does not. The quantities of carp which the compiler has taken by this plan out of the Fobbing Fleets were prodigious; at one draught a flew of twenty yards was so loaded that nine persons could scarcely so ease it up the bank as to prevent its being broken to pieces from the number of carp, of which the smallest did not weigh less than seven, and many of them as much as eleven, pounds each fish; and it was supposed that the bulk together was upwards of seven hundred weight.

In waters where carp have been much used to nets, they become so shy, that the instant they find a net behind them, they endeavour to leap over the cork line. By drawing a second flew about three yards behind the first, they drive headlong into it, after escaping from the first. Mulletts might perhaps be more numerously taken

by this plan than any other, as they constantly leap the nets.

When fishing with flews, either in rivers or ponds, it is most ridiculous to be plunging in and beating the water. (Some employ a rope tied to a horse's skull, others have poles for the purpose, with old shoe soles nailed to the end.) Pike, tench, and perch, will more readily strike the flew when the water is undisturbed and at rest, than from all the violence that can be exerted, and carp flee to and keep in their harbours at the least noise. Flews do more execution at night than in the day, for two reasons, that the fish are then roving about upon their feed, and, that there is no uproar in the water to make them conceal themselves from expected or approaching danger\*.

*The Casting Net* may be successfully employed in a certain depth of water, viz. gudgeon-net at four, and large meshed casting-net from six to eight feet: in the making, great attention must be paid to putting in the widenings, or the net will never open freely, however skilful the person that throws it. In preparing it for casting, it is not to be taken upon the shoulders so short as to prevent the leads having their proper swing, which is to be

---

\* At Hudson's Bay, the Indians have a mode of setting their nets under the ice, by which they supply themselves with great quantities of fish. They first ascertain its exact length by stretching it out, a number of holes are then cut in the ice at ten or twelve feet distance from each other, and sufficiently numerous to extend the net its full length; a line is then passed under the ice, by means of a light pole, which is first introduced at one end of the holes, and with the aid of two forked sticks this pole is easily conducted or shoved from one hole to another, under the ice, till it arrives at the last. The pole is then taken out, and both ends of the line being properly secured, is always ready for use. The net is made fast to one end of the line and hauled beneath the ice, a large stone is tied to each of the lower corners, which keeps the net expanded, and prevents its rising from the bottom. In order to search a net thus set, the two holes at the extremities are opened, the line is veered away by one person, and the net hauled from under the ice by another; after the fish are taken out, the net is easily drawn back to its former station, and there secured as before for future examinations.

aided by the corresponding turn of the caster's body, at the exact moment of delivering it from his arm; and the first object is, to let the leads all break the surface at once. Many persons jerk one part of the net high in the air (which assists the spreading), whilst the other part of the lead-line drops close to the caster's foot, making a variation of some seconds in the fall of the different leads into the water: fish must be very crowded, or extremely sleepy, if they remain within the curtailed range and slow sinking of a net so cast. The nicety of the art is, to be able to cover any particular spot, and to shape the net accordingly; and no one can be deemed a proficient unless he is an *ambidexter*, and throws from either shoulder, as the turning and holes in a river may require.

For carp, or large fish, the mesh should be an inch and three quarters, and the circumference of the lead-line not less than twenty-four yards, and from that to twenty-eight: if made of silk it will sink more speedily, and of course will admit to be thrown with success in deeper water and over weeds. By baiting a place in ponds with grains, worms, or greaves, the fish may be collected, and the casting-net thrown over them: should there be much mud, let the net remain quiet some minutes, and the fish will rise from the mud, into which they have sunk themselves at the noise of the net.

N. B. A piece of crumb of bread put into the stomach of either carp or tench suspected to be tainted with the mud will absorb all the disagreeable taste, and which should be taken out before they are sent to table.

*The Hoop-Net or Drum-Net* is destructive. For large and deep waters, the mesh should be an inch and three quarters, the length full nine feet, and the hoops (of which that in the centre should be iron, rounded like a curtain rod, and painted red, to prevent its rusting) should be strong, and three feet high. In laying hoop-nets, place them where the water gets tolerably deep from a gravelly scour. All the infallible attraction of brass candle-sticks, yellow ribands, flowers, and looking-glasses, are superseded by the arcanum of encircling a live fish brought from other waters in each hoop-net: whether the old inhabitants approach the stranger out of vengeance or curiosity remains a mystery, but that they will run into the hoop-net to get at him the compiler positively insists. It was a secret, which a game-

keeper would not impart, until after being in his service for many years. Old Jonathan always requested to have the management of the hoop-nets left to himself, and would allow of no assistant, and his plan (which was the above) always proved successful.

*Stub-Nets* are very useful in catching carp or trout, when they flee to the banks. They should be made of very strong twine, inch and quarter mesh, be nine feet long, with cork and lead-line; upon which there should be plenty of each: a few widenings should be thrown into the middle, so that there may be a little appearance of a bag; the net is then to be firmly fastened (so that it stands from lead to cork, three or four feet deep) to two ash pitch-fork handles, shod with iron spikes at one end. In surrounding a stub, one spike is to remain fixed in the ground, whilst the other is thrust underneath the stub: the fish thus annoyed, try to regain the deep water, and strike into the bosom of the net, which is then hoisted up, the fish taken out, and the net put down for other trials. If the stubs are very jagged, both spikes are to be stuck in the ground as close as possible to the harbour, and the parties grope with their hands, and those fish which escape their fingers are caught in the stub-net.—*Daniel*.

NEUROTOMY, OR THE NERVE OPERATION FOR FOUNDER. Mr. Percivall, an ingenious veterinary practitioner, with some seeming propriety, having objected to the term *nerve operation* as inexpressive, has named it *neurotomy*; and, as this is at once critical and explanatory of its import, it deserves general adoption. The operation itself is practised for the relief of lameness in the feet, principally of such as are dependent on a contracted or otherwise altered form of the hoofs (the pumiced hoofs excepted). The nerves having been long known as the medium of sensation, many cases of lameness in the feet occur, which render horses useless, principally from the pain and tenderness consequent on the pressure of some pedal parts long since altered by disease, but which are not now actively engaged in a disorganizing process. This very naturally led to an opinion that an interruption of the medium through which they received their sensation (i. e. the nerves immediately furnishing such feet) might, by rendering them wholly or partially insensible, materially remove the impediment, and fit them for useful employ. Such an opinion was entertained

many years ago, and experiments to this effect were made by several ingenious veterinarians. More than twenty years since, Mr. Moorcroft informed me that he had, under this view, been dividing the metacarpal nerves above the fetlock. Similar experiments were afterwards made by Mr. Coleman and by others; but from a want of due attention to all the circumstances connected with it, the practice was not found sufficiently beneficial to warrant its continuance, and it was for many years forgotten, until revived and improved by the ingenuity and research of the assistant professor to the veterinary college. When this operation was first practised, the *reproductive power* in divided nerves, although known, yet was not sufficiently taken into account; consequently as union quickly followed a simple division of their cords, and as sensation soon followed the union, so lameness was found again to recur. But as a knowledge of the functions of the nerves, but more particularly of the peculiarities attendant on operations upon them, became familiar to veterinary practitioners, so the reason of former failures started into view; and it remained for Mr. Sewell, by applying this knowledge to an amended mode of performing the operation, to perfect the discovery, and in fact to make it his own. But the success which attended its practice in the amended state, at first occasioned a too indiscriminate application of it, as well as in some instances an erroneous mode of performing it, both which proved unfavourable to its reputation, and it consequently met with much, and, under such views and practice, deserved opposition. At length, cleared from these fetters, it begins now to assume its proper character, as a limited but valuable auxiliary to the veterinary art.

To do equal justice to the art and to the artist, it may be as well to commence by pointing out the cases in which it has been proved to be inapplicable, and those in which it may be confidently expected to prove useful. Where there is reason to expect considerable disorganization of the internal parts of the feet, as ossification, or total absorption of the articular cartilages, or diseased alteration of the bones within the horny box, or where inflammation of the laminae may have wholly destroyed their sensibility, or where the mucous capsules have, from disease, ceased to yield any, or but a partial, supply of

synovia; in all such cases it cannot be expected to restore the mobility of ankylosed parts, nor can it restore the lost organization; but even in such cases, when morbid processes are not actually going on, but seem stationary, and the animal is rather suffering under the effects of former than of present disease, it has, by rendering the animal less susceptible to the pain of pressure, enabled him to move and exert himself with more ease to himself, and more benefit to his owner. But when an active state of disease is going on, particularly when inflammation is still present, although much disorganization may not have yet proceeded to any great length, or when ulceration of the articular cartilages is suspected, it is not prudent to apply it. Neither is it advisable when the ravages within the feet have been very considerable from any or all the causes above noticed:—on the contrary, in such cases, by removing sensation and rendering the animal willing to exert himself more than the state of the parts will allow, great aggravation of the disease has sometimes followed. For, as has been ingeniously remarked, the naturally acute sensation in the feet is kindly given as a guard to their over-exertion, both in health and under disease. Neither has it been found at all applicable to that state of feet, which at first view appears to have taken on a disease exactly the reverse of founder; that is, where the hoofs, instead of becoming preternaturally high, hard, and lessened in diameter, appear expanded in circumference, but flat, thin, and soft, particularly in the sole, which, from a concave form, has become flat or convex. In these cases, called *pumice-footed*, the operation is, I believe, invariably hurtful. Neither can it with propriety be recommended in any case until all the various means of relief have been ineffectually tried; but when these have completely failed, neurotomy has been found to render many foundered and otherwise foot-lamed horses not only useful, which were before nearly useless, but it has rendered them nearly as perfect in their mode of going as ever. Some have hunted, many have made excellent roadsters, and all have been fitted for carriage-work of every description. The testimonies of this kind detailed in the respective public communications of Mr. Sewell, Mr. Percivall, and Mr. Goodwin, to which I would recommend the inquisitive reader, will

completely remove any scepticism on the subject.

The importance of a due acquaintance with the structure and functions of the various parts of the animal body, are in few instances more exemplified than in the operation under consideration. To experiments on the functions of the nerves we are indebted for the hint, that their division would promote ease to a distressed animal and benefit to his owner; and to a more extended field of inquiry into these important matters, we owe the means of rendering this benefit permanent. Although it seems from these and other reasons which follow, as well as from the extensive experience which Mr. Sewell has had, that he prefers to practise in general cases the lower operation; yet it must be allowed that no great differences have been observed between the ultimate success of the division, whether operated above or below the pastern. It is not, however, to be supposed in either case, that some nervous communication is not kept up by interlacing fibres, from superior branches; for, without this, the common life of the parts would be endangered, and they would be subjected to decomposition and decay. It would be most unphysiological to suppose that, because the motions of the feet were operated by tendons which received their muscular contractions from above, that therefore nervous influence was not essentially necessary for other purposes. On the contrary, in my mind, there is little reason to doubt, that when the hoofs have fallen off some time after the operation, as has happened in a few instances, it has arisen from some failure in the quantity or quality of these auxiliary nervous branches, which forms an additional reason for operating below the fetlock.

The disposition to keep up nervous influence is remarkably observed in the divided portions of nerve in neurotomy. If a simple division be effected, the ends first retract, but afterwards approach each other, and an interposed substance is placed between, which becomes organized, and transmits all the former powers of the nerve. This takes place in about six weeks. Even when a portion of an inch in length is excised from the nerve, the ends endeavour to approach each other, and, though unable to accomplish this, still sooner or later, sensation is transmitted by means of an interposed matter which forms a continuity. The period when this takes place is not defi-

nite; it has occurred in a few months, and it has taken three years to do it: it is said, in some few cases, sensation has not returned at all. On the return of sensation, it now and then happens, that lameness also returns, but it is consolatory to know, that a repetition of the operation has wholly removed the secondary attack. When no lameness returns, there is reason to suppose that the disease itself is overcome, and facts have borne out the supposition. Some enlargement usually remains under the skin, from a thickening of the divided portions, which has been sometimes so considerable, as, in the high operation, to bring the part within the reach of the contrary foot in its elevation. When, therefore, it is wished to perform the division above the fetlock, it has been proposed, in order to avoid this inconvenience, to operate *above* on the outer and *below* on the inner side.—*Blaine.*

NICKING. There can be very little doubt but this operation originated in a wish to prevent the inconveniences resulting from the force with which a horse carried a long tail around him, to the annoyance of his rider. Tails were therefore first tied up in “stiff buckle;” they were then shortened or docked; and, lastly, from an observance that, under impetuosity, or stimulated by any excitement, the tail was elevated. Animation, which is but another term for beauty and grace, became inseparably connected in the mind with the rising of the tail, and artificial means were used to make such elevation constant in ordinary exertion. In a natural state, the depressing muscles of the tail are stronger than the erecting; and it is to overturn this, and to give the balance of power to the erectors, that the operation of nicking is practised. The introduction of blood horses into general use, has greatly modified the mode of nicking, and instead of three sections to form a perfect *nag tail*, the drooping, pendent, elegant curve of the blood horse requires but one. As in castration, so also with nicking, a seasonable time should be chosen for it. In cold weather, it may become checked in its granulating process; and in very hot weather, locked jaw will be more likely to supervene.

The modes of securing the horse for the operation are various. Some few do it in the break or trevis; others place him against a strong bail, across a stall, or a leaping bar; which modes are practised by grooms and horse dealers, who

are often very expert at nicking, and who seldom, if ever, cast a horse for the purpose. Professional practitioners, I believe, most of them, used to throw the horse for this operation: for many years (says Blaine) I never operated without so doing; but I became averse to it from the difficulty of making the sections of equal depth, and likewise from the dangers of casting; but more than all, from every day seeing horse dealers performing it with the greatest ease and security standing.

It should, however, be remembered, that unless the practitioner be very expert at using the side lines, and have all the necessary conveniences, it will be safer for him to operate by casting: for want of these precautions, I remember, a few years ago, a horse dealer being killed on the spot while nicking a horse one Sunday morning in London.

*Mode of operation.* The horse being properly secured (if by the side line, two had better be used), and a twitch being ready for both lip and ear, endeavour to gently place first one, and then the other, hind leg, as far under the belly as the horse can bear with comfort, but not farther, or it will increase his disposition to resistance. If it be suspected that he will prove very obstreperous, or any timidity exist in the mind of the operator, as a further security, include both hind legs in another rope, or in a wide web, a little above the hocks. This may either run in a noose, or, which is better, let each loose end be attached to a manger ring, or, if operated out of doors, fasten them around the neck or across the breast. The tail having the hairs of the dock first bound together with wax end, &c. as the future means of attachment to the pulleys, and also, if very full of hair, having it plaited back and secured, prepare to use a short stout scalpel; if double-edged, it is more convenient, and will save trouble in turning. The mode of making the sections must be left to the discretion of the operator, but the junior practitioner will find himself materially assisted by an accurate acquaintance with the anatomy of the tail. He will then see that the tail is neither conical nor perfectly cylindrical, but somewhat quadrilateral: its upper angles being formed of the fleshy bellies of the coccygeal elevators, and its lower of the depressors, leaving the under surface of the tail covered with ligament and skin only. It is of the utmost consequence to the junior operator that he bears this in mind, and

that he does not penetrate farther than the skin at this part, or he may divide the ligaments, and even penetrate the joint between one coccygeal bone and another, when ankylosis and a stiff tail would ensue. This latter accident may, however, be readily avoided by making the sections in the centre of a tail bone, which may be distinguished by the prominences of its articular surfaces; between which no such accident can happen. It is sometimes directed, and practised also, to make a section first through the integuments only, beginning at the roots of the hair on one side, and carrying it across the bellies of the depressor muscles; then doing the same on the other side; and, lastly, making these sections meet by a light and careful division of the integuments only, on the median line of the tail. Such is a very cautious and proper mode for the tyro, and is consistent with the best principles of the art; but it somewhat delays time, and the expert practitioner will probably find it more ready to carry his scalpel at once through the depressors, by a steady sweep, embracing all the parts to the median line, casing off the depth of section as he approaches it. By turning his hand, the same may be done on the other side, by which two strokes, judiciously performed, the operation, in expert hands, is at once complete. This first section should not be nearer in the smallest horse than two inches and a half, and in a full sized three inches, or three and a half, as the centre of the coccygeal bones may indicate. If another section be wanted, make it at two inches and a half or three inches from the first and the third, if it be necessary, somewhat less distant than the others; but in blood horses, one or at most two sections, according to the fullness of croup and height of the sacral line, is all that will be at the present day required. In mares of whatever breed, one section less than for the horse is advisable. The most expert operator will, however, find it prudent, when the sections are made, to examine them carefully that they are all of equal depth, and have divided the depressor muscles completely. Should any difference appear in these respects, and should such unequal division be allowed to remain, the operation would be incomplete, and the horse would probably carry his tail awry. Add to which, any portion of the muscle being left undivided, would tend to prevent the others from retracting, and might also serve to promote a

re-union of them. Having proceeded thus far, the hæmorrhage which ensues need not be considered as of consequence, nor will it shew itself until the tail be wholly relaxed; while it is elevated therefore, proceed to remove the tendinous ends, which will bulge out, not being retracted with the divided ends of their accompanying muscles. If one section only be made, they will be less prominent than where there are more; but enough will always protrude to enable them to be laid hold of by a tenaculum or forceps, and then cut off by a pair of strong and sharp scissors. The removal of these will not only separate the attachments of the muscles farther from each other, which, if re-united, would of course frustrate the operation, but their removal greatly facilitates the healing of the wounds.

The sections being thus complete, proceed to restrain the hæmorrhage, which is done in various ways. By some, by means of strips of cotton, tow, hemp, &c. which, twisted and inserted into each nick, are separately tied on the back of the tail. My own practice of late was to tie a piece of lint on a pledget of tow, and introduce into each section, sufficient to fill it up, over which I placed linen strips long enough to tie, on the back of the tail, which were then tied sufficiently tight to restrain the hæmorrhage. Here also it behoves the practitioner to consider the principles of his operations. He purposely strangulates the tail to prevent a dangerous waste of blood, but the very action is an incipient death to the part, and therefore should be most carefully guarded against that it does not proceed too far. If the bleeding be considerable, and require the bandages to be made very tight, I usually loosen them a little in two hours, watching the wounds; but when these ligatures are not necessarily so tight, they may be allowed to remain all night, but should be snipped in two at the back of the tail in the morning, which will not disturb the tail: indeed, whatever the degree of stricture or tightness used in the application of the ligatures, as soon as symptoms of strangulation have commenced, less risk will be run by a too early than by a too late division. When the practitioner is on the spot, an examination of the tail may be made in the evening previous; and in case any reaction has commenced, and the tail is very hot, loosen or divide them at once on the evening of the day of the operation, when, if the re-action appear to be con-

siderable, which will be known by the tail becoming very hot, it will be prudent to divide them at once, and this more particularly if the operation has been performed early in the morning. Much difference of opinion has prevailed on the subject of dressings, and whether any medicament were proper beyond dry lint. If it were possible to promote the adhesive union, then a dry dressing would be the best; but when it is considered that an early and healthy suppuration is, in human surgery at least, thought to be some guard against tetanus, and as it will enable the dressings to be removed with less difficulty, so there can be no objection to any mild digestive being made use of, if it fall in with the view of the operator. Many of the best veterinarians, however, content themselves with simply watching the nicks, that they be kept clean and free from fungus or other unhealthy process, which, if they do not occur, they use no applications but the bandages.

It is evident that, were a nicked tail left to itself, the depressing muscles would reunite, and carry it nearly as before: a suspension of the tail afterwards is therefore necessary to keep the divided ends of the muscles apart until a cicatrix be formed, and such junction thereby prevented. Various means have been used for this purpose. Formerly the tail was fastened on the back, to the danger and torment of the animal. It is now suspended by means of pulleys, the best of which are double. When one is used, one wheel is passed through a line stretched across the end of the stall, rather behind the horse, and through the other wheel the line to which the weight is appended. A more improved mode is used by means of two of these pulleys, one of which is placed directly behind the horse, at some distance from him, through which, after passing through the pulley on the cross line, it is also passed. By these means, whatever be the motions of the horse, the tail is distended at a right line with the body. The weight used for this purpose should be such that, for the first day or two, it will hardly keep the tail straight, or more than straight; for two or three more, elevate it to a little above the horizontal line, advancing it every two or three days to the required height, but which should never be carried perpendicularly erect. The elevation ought, however, principally to depend on the height to which we wish the tail to be carried in future. The carriage of the

tail should therefore be examined every two or three days, bearing in mind that, after it has altogether done with the pulleys, it frequently, indeed commonly, drops a little.

Among farriers and horse dealers, some difference of opinion has existed, relative to the propriety of exercising a horse during the use of the pulley, and also as to how long the pulley should be used ; but these matters can never puzzle the veterinarian, being easily solved by a knowledge of the general principles of the animal economy, which alone ought to guide him. The pulley is only an extension of the tail, to keep the ends of the muscles from uniting again ; but the simple extension does nothing of itself, as is foolishly supposed, towards the making the horse carry it in future. As soon, therefore, as the wounds are closed, or nearly so, then all the benefit from the pulley is finished ; but till then, of course, the muscular ends may unite, and frustrate the operation. Sometimes incrustation of the wounds will take place in ten days or a fortnight, and sometimes it will take a longer time. With regard also to the propriety of exercising the horse, there ought to be but one opinion. As the hair is, or ought to be, platted and carefully secured, so no inconvenience can arise, but every benefit may be gained, from letting him from the pulleys, and exercising him gently to remove swelling, &c. &c. The hair being put on the stretch by the force used, so a great part of it usually comes off, and this will happen in spite of every precaution ; but the longer it is kept in one immediate position, so much the more certain it is for much to fall off. At the end of five or six days, therefore, it may be untied or unplatted, combed out, and then tied afresh, being first greased at its roots ; and the same may be repeated every three or four days afterwards, which is the best means I have found of preventing it from falling totally off.

Having thus carried the operation through its ordinary course, it remains to say somewhat of its irregularities. Occa-

sionally inflammation follows the operation, either from suspending too much weight to the pulley, or forcing it backwards ; or otherwise from too long continuance of the ligatures, or too great tightness. This may proceed to mortification, or it may leave the tail with an unhealthy ulceration producing sinuses. When the former happens, the horse shews evident uneasiness the second or third day, the tail swells, is very tender towards the rump, and the heat is excessive. If the dressings be removed, the wounds appear highly inflamed and tumefied ; and unless this inflammatory state be arrested by the most active means, the wounds will become gangrenous, the stump will feel cold and mortification will proceed towards the body, and either destroy the horse ; or it is sometimes arrested at the base of the tail, and at length suppurates and drops off. In such cases the treatment must be prompt, and exactly that already detailed for active and important inflammations. As part of such treatment, remove it from the pulleys, or only very slightly suspend it ; wetting the tail frequently with cold water ; keeping it continually so, will be found even more useful. It will also be a proper plan to apply cold water during the common process, whenever the tail is at all hotter than is wished. Another evil to which these cases are exposed is tetanus or locked jaw, and which is brought on by causes unapparent to us : in some instances, however, heat in the temperature of the air seems to operate on it. It makes its appearance in many cases about the fourth or fifth day, and occasionally later. As a precursor to it, the wounds occasionally assume an unhealthy aspect, and suppuration ceases. In other instances no such alteration appears ; but in every instance, besides the general treatment of tetanic cases, the tail should be most actively stimulated, or otherwise really amputated, which perhaps would be the most proper.

NIDE. This term is applied to the offspring or young of the pheasant, before they separate.

**NIDIFICATION OF BIRDS** is one of those wonderful contrivances of nature that would compel us to believe that we and every other part of the creation are ever under the protection of a superintending Being, whose goodness knows no bounds, and who is alike provident for the preservation and comfort of the inferior, as well as the highest, order of his creatures. The art in the construction of

the nests of birds would baffle all the boasted talents of man to imitate :—

----- Mark it well; within, without :  
 No tool had they that wrought, no knife to cut,  
 No nail to fix, no bodkin to insert,  
 No glue to join; their little beaks were all;  
 And yet how neatly finished. What nice hand,  
 With every implement and means of art,  
 And twenty years' apprenticeship to boot,  
 Could make me such another? Fondly then  
 We boast of excellence, whose noblest skill  
 Instructive genius foils.

Speaking of the conduct of birds to their young, Derham observes “How well they caress them with their affectionate notes; put food in their mouths; teach them to eat and gather meat for themselves; and, in a word, perform the part of so many nurses, deputed by the sovereign Lord and preserver of the world to help such shiftless creatures!” Neither ought it to be forgotten how much the instinct costs the animal which feels it:—“How much for example (says Dr. Paley) a bird gives up by sitting upon her nest; how repugnant it is to her organization, her habits, and her pleasures? An animal formed for liberty submits to confinement in the very season when every thing invites her abroad. What is more, an animal delighting in and made for motion, all whose motions are so easy and so free, hardly a moment at other times at rest, is for many hours and days together fixed to her nest as close as if her limbs were tied down by pins and wires. For my part (continues Dr. Paley) I never see a bird in that situation, but I recognise an invisible hand, detaining the contented prisoner from her fields and groves, for a purpose, as the event proves, the most worthy of the sacrifice, the most important, the most beneficial.”

But the loss of liberty is not the whole of what the procreant bird suffers. Harvey tells us, that he has often found the female wasted to skin and bone by sitting upon her eggs.

Dr. Paley observes, that the *pairing* of birds, and the *non-pairing* of beasts, forms a distinction between the two classes, which shews that the conjugal instinct is modified with a reference to utility, founded in the condition of the offspring. In quadrupeds, the young animal draws its nutriment from the body of the dam. The male parent neither does nor can contribute any part to its sustentation. In the feathered race, the young bird is supplied by an importation of food, to procure and bring home which, in a sufficient quantity for the demand of a numerous brood, requires the industry of both parents. In this difference we see a reason for the vagrant instinct of the quadruped, and for the faithful love of the feathered mate.

NIGHT-MARE. A malady incident to horses as well as human beings, and proceeding from the like causes. This complaint causes the horse to sweat more in the night than in the day, and thereby deprives him of his rest. You may discover it by observing him in the morning, whether he sweats on the flanks, neck, short ribs, which are strong indications of it. For the cure, the tribe of remedies

termed *nervous* are probably required, particularly the fetid gums and the bark, preceded by a mercurial purge.

Mr. John Lawrence says, "There can be no doubt that horses are frequently troubled with the *asthma nocturnum*, *incubus*, or *night-mare*: the symptoms of which are those profuse sweats, and twisting and disheveling of the mane, discovered at their uprising in the morning; which the country fellows of old attribute to the jockeyship and hard post-work of Oberon and his queen. The cause is a dense and sizzly blood, and intestinal accumulation. It is one of the salutary warnings of beneficent nature, which is not always neglected with impunity." Venesection, purgatives, exercise, and grass, are the remedies he prescribes.

**NIPPERS.** Four teeth in the fore part of a horse's mouth, two in the upper and two in the lower jaw. They appear between the second and third year. See **AGE OF HORSE.**

**NOSEBAND** is that part of a military bridle, headstall, martingal, or hunting rein-halter, which, passing below the under jaw, and round the nose above the nostrils, assists in keeping the other parts of either in their proper positions.

**NOSTRILS.** The nostrils of a horse are generally supposed to be a tolerable criterion of his wind, as well as his blood. A horse having a wide and well-extended nostril, may be supposed to possess a free

and easy expansion of the lungs: this cannot be more perfectly comprehended, than by adverting occasionally to the shape of horses which race, and are thorough bred; where the form and expansion of the nostrils will be found more than one third larger than such horses as are of common lineage, and inferior description, and arises perhaps from their swift exercise and swift work.

**NOVEMBER.** This may be called the sportsman's meridian, as the diversions of the field, generally speaking, may all be pursued. It is true, grouse will have become very wild, and partridges, unless where they are abundant, and little disturbed, will not easily allow the approach of the shooter; but cover shooting may be enjoyed in perfection, and this month is, in fact, the very zenith of pheasant and woodcock shooting.

Coursing, and the pursuit of the hare with hounds, may now be followed without interruption.

The regular season for fox hunting commences generally at the beginning of this month; in some places rather earlier.

Wild-fowl make their appearance in the month of November; and are seen earlier or later, and indeed numerous or otherwise, according to the severity of the season. The early and numerous appearance of wild-fowl may be regarded as an indication of a severe winter.

## O

**OATS.** A well known grain, which constitutes a material part of the diet of horses.

Gibson reckons them to be of a middle nature between wheat and barley. They agree well, and are generally so palatable to horses, that he never knew even a foreign horse, that had been used to barley and other kinds of grain, refuse to eat them. Yet many of our horses will not relish barley, unless it be scalded, or they are first suffered to be very hungry, and even then they do not care to eat it. "Oats (says he) are cleansing and opening, and our horses seldom receive any damage from them, unless given with too liberal a hand, and then they are looked upon to be heating. Besides, when horses have too many oats given them, they are apt to eat little or no hay. But this seldom happens, except where hay is scarce, or not good of its kind, and oats are plen-

tiful; but horses that eat little hay and many oats, though their flesh is generally firm, yet they seldom carry any belly, and, if they have not a good deal of exercise, are apt to fall into fevers.

The oats are generally good all over England, but are best in the north parts; for they thrive most in cold moorish grounds, and in some countries are their chief product. Those that have a thin shell and not large and husky, feel heavy in hand, and rattle when poured into the measure, are the best. The ship oats that come to Bear-Key are chiefly from the northern counties, but are sometimes musty and unwholesome, and lose their whiteness by the water carriage; but when they are put into dry granaries or dry lofts, and spread out on the floors, and often turned and sifted, they frequently recover their sweetness, and may be given with safety; yet I should always

prefer the freshest and newest oats, especially for fine horses, though they may be worse in kind; and where they abound in husk there needs no more than to increase the allowance. Some prefer the black oats to the white, but I believe the difference is but small, only that in some places the black are more firm and hard than the white, and have a thinner shell, and in those places they generally sow a superior number of black oats among the white, though the white that grow up with them are not much, if at all, inferior to the other, which shews the difference lies chiefly in the goodness of the seed and the fitness of the soil."

**OBERON.** A bay horse, foaled in 1782, bred by and the property of his Grace the Duke of Grafton.

Oberon was got by Florizel; his dam, by Snap; grand-dam, Blank Mixbury.

At Burford, August 11, 1785, Oberon won 50l. for three years old, colts 8st. 4lb. fillies 8st. 2lb. beating, at three two-mile heats, Lord Abingdon's Monarchy, and Mr. Lade's brown filly, which was distanced the first heat. At Swaffham, September 26, he won 50l. for three years old colts and fillies, 8st. each, one mile, beating Lord Abingdon's Monarchy, Mr. Hale's Icarus, Mr. Hull's Drover, Prince of Wales's Figaro, Mr. Vernon's Bedford, and two others. At Newmarket second October meeting, he won 50l. for three years old, colts 8st. fillies 7st. 12lb. A. F. beating Mr. Lade's Pilot, Sir C. Bunbury's Blackcock, Lord Egremont's brown colt, by Highflyer, out of Angelica, Lord Vere's Fox, Lord Grosvenor's Grantham, and Mr. Hull's Little Anthony:—3 to 1 against Oberon, 3 to 1 against Lord Egremont's colt, 3 to 1 against Little Anthony, and 4 to 1 against Grantham.

At Newmarket first spring meeting, 1786, Oberon won 50l. three-year olds, 7st. 4lb.; four, 8st. 7lb.; and five, 9st. D. C. beating Sir F. Evelyn's Egham, 5 years old; Mr. Vernon's Trusty, 3 years old; Prince of Wales's Figaro, 3 years old; Mr. Stacie's Bacchus, 4 years old; Mr. Clarke's Trinidado, 5 years old; and Duke of Queensbury's Cutter, 4 years old:—7 to 4 against Oberon, and 3 to 1 against Bacchus. In the second spring meeting, he won the Jockey Club purse, for four-year olds, 8st. R. C. beating Sir F. Standish's Lepicq, Lord Grosvenor's Vulcan, Mr. Maynard's Smith, Mr. Wentworth's Cowslip, and Mr. Bullock's Lunardi:—5 to 2 against Oberon, and 4 to 1 against Lepicq. In the July meeting,

at 8st. he won 60gs. for all ages, D. I. beating Mr. Dawson's Roscius, 5 years old, 8st. 8lb.; Mr. O'Kelly's Soldier, aged, 9st.; Mr. Lade's brown filly, by Highflyer, 3 years old, 6st. 9lb.; Mr. Hull's Alphonzo, aged, 9st.; Sir C. Bunbury's Volatile, aged, 9st. and Lord Grosvenor's Roundelay, 4 years old, 8st. —6 to 5 against Soldier, 5 to 2 against Oberon, and even betting either Soldier or Volatile won. In the first October meeting, at 7st. 7lb. he won the 140gs. subscription, for all ages, B. C. (seven subscribers,) beating Lord Derby's Peru, aged, 9st. and Lord Foley's Blandish, 4 years old, 7st. 7lb.—4 to 1 on Oberon.

At Newmarket second October meeting, 1787, Oberon, 7st. 12lb. beat Lord Clermont's Collector, 8st. 3lb. last three miles of B. C. 50gs:—6 to 4 on Collector. He afterwards proved unsuccessful in England, and was sold to Noble Mannis, Esq. who raced him in Ireland.

At Limerick, July 9, 1788, Oberon won 50l. for six-year olds and aged, 8st. 12lb. each, four mile heats, beating Mr. A. Daly's Friar, aged; Mr. M'Craith's Tulip; Mr. Hamilton's Trifle, 6 years old; Mr. Hewson's Munster Lass, aged; and Mr. Strange's Tormentor: Trifle the favourite; after the first heat, 2 to 1 on Oberon. Next day, he won 50l. for all ages, beating Mr. Kirwan's Hippomenes, 4 years old, and Mr. Dennis's Kildare, 5 years old. At Kilkenny, July 31, he won 60gs. for six-year olds, 9st. each, two-mile heats, beating Mr. Dennis's Ranunculus, and Mr. Hamilton's Tommy Orde. He afterwards proved unsuccessful.

**OCTOBER.** On the first of this month the pursuit of the pheasant becomes a legal object with the sportsman; grouse have become wild, but good diversion may still be obtained with the partridge. Some few woodcocks will most likely make their appearance towards the end of this month.

Coursing is in full activity. The hare is pursued also by the harriers.

Fox-hounds are busily employed: cub hunting; and, in some parts of the kingdom, the regular season commences towards the end of the month.

**OFF-SIDE.** The right-side of a horse, if you stand parallel with him, and look the same way, is the off-side; as the left is the near-side. When speaking of any part of a horse, it is not usual, in sporting terms, to use the words right or left; but to say the near-shoulder; the off-eye; the near-leg before, or the off-leg behind.

**OIL, AND THE BEST MODE OF CLARIFYING IT.** All vegetable oils possess a harder quality, and are more apt to become cloggy, than animal oils; and are, consequently, not so well calculated for the fowling-piece, the locks in particular. Neat's-foot oil, and the oil from sheep's feet, generally contain a considerable quantity of feculent matter, which may be separated by the following simple process:—drop a few small pieces of lead into the bottle, and hang it in the sun for a week or ten days, when the residuum will sink to the bottom, leaving the oil remarkably pure, and admirably adapted for the purpose just mentioned. If it happens in the winter, when the sun is not sufficiently powerful, hang the bottle near the fire, to keep the oil perfectly fluid, otherwise the residuum cannot sink. —Goose grease, or the fat of fowls in general, will answer the purpose fully as well, if clarified in the manner above described. Oil thus prepared is far superior to any other for the lock, &c. of the fowling-piece; and indeed for all similar mechanism.

**OLD BACHELORS.** There are few experienced shooters, I apprehend, who have not frequently met with small coveys of partridges, which consisted entirely of male birds. These small coveys are evidently made up of individuals who have not been able to find mates, and which, at the latter end of the summer, congregate, and appear to live in the greatest harmony—a striking instance of the social disposition of the partridge. They are called old bachelors.

**ONION** is an article which would not have found its way here, but in consequence of its great utility upon a certain emergency, which entitles its property to be more universally known. No trifling occurrence can possibly occasion more temporary mortification to a sportsman than to see his horse labouring under the

strangury (or suppression of urine) after the long stage of a journey, or the severity of a chase. In such cases, the first farrier is generally called in, who, proceeding upon the *kill or cure* system of former times, prepares a portion of the most powerful urinary stimulants, plentifully besprinkled with spirits of turpentine, oil of juniper, and other equally violent and injudicious ingredients, frequently laying the foundation of inflammation; when an onion being peeled, and a small clove or two of the inside properly insinuated within the sheath, may nineteen times out of twenty be expected to produce the desired effect, without the interposition of any medicine whatever.

**OPENING THE HEELS.** The ceremony of opening a horse's heels is sometimes necessary, when they are become contracted by so constantly standing upon the dry litter, and hot dung of stables in the metropolis; a circumstance which occurs much less in the country, where the defect is but little known. Although there can be no doubt of a hoof's contracting in a great degree by the means already mentioned, it must be more so, where the hoofs are not moistened or stopped for weeks, or probably months, together. It is, however, a matter of doubt, whether the back-handed stroke of the smith's rasp in shoeing, is not a more constant or frequent cause of the narrowness of the heels than any other. Let it arise from whatever cause, the remedy with them is always ready; "open the heels;" or, in other words, cut away with the drawing-knife, till little or nothing is left: when the basis of bearing is taken away, the heel is let down to the ground, the tendons are put upon the stretch, the horse being divested of his natural support, hobbles like a cripple, and there is no remedy, but to wait with patience for a perfect regeneration of parts so wantonly destroyed.

**ORTOLAN.** The ortolan or wheat-ear, inasmuch as in some parts it is sought after by the sportsman, merits particular notice in this place. This species is met with in all parts of Europe, even so far as Greenland; and Latham says he has seen specimens sent to England from the East Indies. The ortolan visits England annually in the middle of March, and leaves us in September; and about that time they are seen in great numbers by the sea shore, where probably they subsist some little time before they take their departure.

The ortolan and the wheat-ear we regard as one and the same bird, though we are aware that a distinction has been made by some writers, which we look upon as incorrect. These birds appear in

## ORTOLAN

great numbers in some parts of England, and are much esteemed. They feed on small earth-worms, and therefore resort to ploughed fields. About Eastbourn, in Sussex, they are taken in snares made of horse hair, placed by the shepherds beneath the hollows of a long turf cut out for the purpose. The length of the bird is about five inches and a half; the bill black and more than half an inch long; the top of the head, hind part of the neck and back, are of a blueish grey; from the base of the bill a black streak extends over the eyes, cheeks, and ears, where it widens into a large patch, and above this there is a line of white. The quills are black with tawny edges; the rump, upper tail coverts, and base half of the tail, white, the rest black. The under parts of the body yellowish white, changing to pure white at the vent. Legs and feet black. In the female, the white above the eye is somewhat obscure, and all the black parts of the plumage incline more to brown, nor are the tail feathers marked so deeply with white. Such is the description given of the wheat-ear.

These birds frequent heaths; and, except in particular spots, are only seen in a few scattered pairs. The nest, which is placed in new ploughed lands under stones, or sometimes in old rabbit burrows, is constructed with much care, and is composed of dry grass or moss mixed with wool, and lined with feathers: it is defended by a sort of covert fixed to the stone or clod under which it is formed, and is always made on the ground. The eggs, from five to eight in number, are of a light blue, with a circle at the large end of a deep blue. The young are hatched the end of May or early in June.

Having described what in England is called the wheat-ear, we shall introduce the description of the ortolan of the Continent, which, notwithstanding the seeming difference, we are, nevertheless, disposed to consider as the same bird.

The ortolan, we are told, is something less than the yellow-hammer: bill yellowish, the head and neck are cinereous olive; throat and round the eyes yellowish; the breast and belly are red, and the upper part of the body brown, varied with black; tail deep brown with rufous edges, excepting the outer feather, which is edged with white, and the inner part of the neck to it, tipped with white; though in some birds, the outer feather is marked obliquely with white near the end, with a brown tip: legs yellowish. The female differs in having the head and neck inclining to ash colour, marked with small blackish lines down the shaft of each feather; otherwise like the male.

There is certainly some difference in the description of the wheat-ear and the ortolan, which, however, might arise from the different state of the plumage, as we conceive (as we have already observed) that they are one and the same; that in fact the wheat-ear of this country is the ortolan of the continent; and is in all probability the celebrated *Miliaria* of Varro. Long before his time it was known at Rome, where it was kept in the aviaries along with the quails and thrushes.

The ortolans, when fattened, are prepared for the table in various ways. Sometimes they are roasted in a natural or artificial egg-

## O T T E R

shell; a mode of cookery borrowed from the ancients, who not only dressed small birds, but presented them at their entertainments in this manner; so that upon opening the egg, they were seen floating amidst a high-seasoned sauce. The delicacy of the flesh rather than the powers of song, recommended the ortolan to the luxurious Romans, and laid the foundation of their fame in the ancient world: this species will, however, sing prettily both by day and night, and has been kept for that purpose.

Ortolans are found in several parts of Europe; are common in France and Italy, and some parts of Germany and Sweden; migrating from one to the other in spring and autumn; in their passage they are caught in numbers, in order to fatten for the lovers of good eating. This process is easily managed by inclosing the birds in a dark room, setting before them plenty of oats and millet, with which they soon grow so fat, that they would die from that cause alone, did not their feeders kill them for the emolument of their sale. Their flesh is thought to be one of the most exquisite morsels yet known, being, as it were, a lump of rich fat, and the birds arrived at this state will often weigh three ounces. It is impossible, we are told, to eat a large quantity of this food, provoking as it may be, as it palls on the appetite by its richness; and nature, as in other instances, so here, has placed disgust before excess, as a guard against the intemperance of the glutton.

Ortolans are also very common in the south of Russia, and in Siberia as far as the river Ob, but never go much to the north. The arrival of the ortolans in France is nearly at the same time with that of the swallow, and they take their departure with the quail. They are lean on their first appearance, which is during their season of love. In some parts they make their nest in a low hedge; in others on the ground. It is carelessly constructed, similar to that of the lark.

In India, we are told, that towards the conclusion of the cold season, that is, about the beginning of March, the ortolans make their appearance, and assemble in such flights as can be compared to nothing better than immense swarms of bees. They are most numerous in April and May, especially if the squalls of wind and rain, called north-westerns, be not frequent; those violent gusts disperse them. In clear hot weather, perhaps a score of large flights may be seen in various directions: they are not very difficult to approach; indeed, whole flights will sometimes settle close to the persons who happen to be on a favourite or inviting spot. Though many may be killed by firing at random, while the flock is on the ground, it is best to kill them on the wing: Major Ducarel once killed more than thirteen dozen by one discharge of dust shot at a flight that passed close to him.

OTHELLO. See BLACK-AND-ALL-BLACK, page 62.

OTTER. This creature seems to form that link in the chain of gradation which unites terrestrial and aquatic animals, and is uncommonly destructive among fish; it presents the form of the quadruped, but resembles aquatic animals in being able, not only to swim with great speed, but also in being able to remain for a con-

## O T T E R

siderable length of time under water. The otter, however, properly speaking, is not amphibious ; he is not formed for continuing in the water, since, like other terrestrial creatures, he requires the aid of respiration ; also, if, in pursuit of prey, he gets entangled in a net, and has not time to cut with his teeth a sufficient number of meshes to effect his escape, he is drowned. The usual length of the otter, from the tip of the nose to the base of the tail, is twenty-three inches ; of the tail itself (which is broad at its insertion and tapers to a point) sixteen ; but one drowned, by being entangled in a fisherman's net near Bath, in 1805, measured, if we are to believe the account (which appears to us more than suspicious) upwards of *six feet* ! The weight of the male is from eighteen to twenty-six pounds ; that of the female from thirteen to twenty-two pounds :—one, in October, 1794, was snared in the Lea river, between Ware and Hertford, which weighed upwards of forty pounds. The head and nose are broad and flat, the eyes are brilliant, though small, are nearer the nose than is usual in quadrupeds, and placed in such a manner as to discern every object that is *abore* ; which gives the otter a singular aspect, somewhat resembling the eel ; but this property of seeing what is above gives it a particular advantage when lurking at the bottom for its prey, as the fish cannot discern any object *under* them, and the otter, seizing them from beneath by the belly, readily takes any number with little exertion : the ears are extremely short and their orifice narrow ; the opening of the mouth is small, the lips are capable of being brought very close together, somewhat resembling the mouth of a fish, are very muscular, and designed to close the mouth firmly, while in the action of diving, and the nose and corners of the mouth are furnished with very long whiskers. This animal has twenty-six teeth, six cutting and two canine above and below, of the former the middlemost are the least ; it has besides five grinders on each side in both jaws : the legs are very short, but remarkably broad and muscular, the joints articulated so loosely, that the otter can turn them quite back, bring them in a line with its body, and use them as fins ; each foot has five toes, connected by strong webs, like those of water-fowl : thus nature in every particular has attended to the way of life allotted to an animal, whose food is fish, and whose haunts must necessarily be about the waters. The otter has no heel, but a round ball under the sole of the foot, by which its foot-mark is easily distinguished, and this is termed the *scal*. The general shape of the otter is somewhat similar to that of an overgrown weasel, being long and slender ; its colour is entirely a deep brown, except two small spots of white on each side of the nose and one under the chin ; the skin is valuable, if the animal be killed in the winter, and makes gloves more durable, and which at the same time will retain their pliancy and softness, after being repeatedly wetted, beyond any other leather.

The otter shews great sagacity in forming its abode, burrowing under ground on the banks of some river or lake ; and generally making the entrance of its hole under water, working upwards towards the surface of the earth, and forming several holts or lodges,

## O T T E R

that in case of high floods it may have a retreat (for no animal is more careful to repose in a dry place) and there making a minute orifice for the admission of air; and even this aperture, for greater concealment, is frequently made in the middle of some thick bush.— Sometimes its retreat is made in the hollow trunk, or upon the top, of a willow pollard that inclines over the water. The otter is very cleanly, depositing its excrements or *spraints* in particular spots. Upon the least alarm it flies to the water, where, by its rapidity in swimming and diving, it frequently escapes from its pursuers.

In rivers the otter is always observed to swim against the stream to meet its prey; and in very hard weather, when its natural food fails, the otter will kill lambs, sucking pigs, and poultry; and one was caught in a warren where it had come (it is supposed) to prey on rabbits. The otter will also devour vegetables of different kinds, and gnaw the bark and twigs of young trees.

In the year 1793, as two gentlemen were shooting in Devonshire, the pointer stood at some brakes, from which a large otter issued; the dog seized it; but, being severely bitten, quitted his hold: after driving the otter about for some time in a turnip field, his destruction was effected by blows upon the head; and this otter was at a distance of at least five miles from any river or pond that could supply him with fish, and it is to be presumed he meant to prey upon some land animal, as he had prowled so far from the place where his natural food could be procured.

This occasional rambling of the otter from its favourite element seems to be one of its habits. At Hudson's bay they are frequently seen in the very depth of winter, both in woods and on open plains, as well as on the ice of large lakes, at a considerable distance from any known open water. If pursued when among the woods in winter (where the snow is always light and deep) they immediately dive into and make considerable way under the snow, but are easily traced by the motion of it above them, and soon overtaken. Otters are very fond of play, and one of their favourite pastimes is, to get on a high ridge of snow, bend their fore feet backward, and slide down the side of it sometimes to the distance of twenty yards. They have from three to five young at a time. In summer, when the hair is very short, they are almost black, but as the cold weather advances, they become lighter coloured.

The flesh of this animal is extremely rank and fishy; but we are told the Romish church allows its use on *maigre* days. In the kitchen of the Carthusian Convent, near Dijon, Mr. Pennant says that he saw an otter preparing for the dinner of that rigid order, who, by their rules, are prohibited, during their whole lives the eating of flesh.

As the otter frequents ponds near gentlemen's houses, litters of young have been found in cellars, soughs, and drains. The cubs have been known to have been suckled and brought up by a bitch: near South Molten, in Devonshire, this happened, and the young otter followed his master with the dogs, but seemed to have no inclination for the water.

## O T T E R

There are many instances of the otter being tamed when taken young, and becoming so domesticated as to follow their master, answer to a name, and employ their talent in fishing for him.

William Collis, of Kemmerston, near Wooler, in Northumberland, had a tame otter which always attended him, would fish in the river, and when satiated return to him. In Collis's absence, his son took the otter out to fish ; but it refused to come to the accustomed call and was lost : the father, after several day's search, being near the place where it was lost, and calling by its name, it came creeping to his feet, and shewed many marks of firm attachment.

James Campbell, near Inverness, had likewise a tame otter, which was frequently employed in fishing, and would take eight or ten salmon in a day. If not prevented, it always attempted to break the salmon behind the fin next the tail. When one was taken from it, it dived for more, and when tired and satisfied with eating the share of the prize allotted it, the animal curled itself round and fell asleep, in which state it was generally carried home. This otter fished, as well in the sea, as in a river, and took great numbers of codlings and other fish.

Fishing with the tame otter is mentioned by Vaniare in his *Prædium Rusticum*, and the passage has been thus translated :—

Should chance, within their dark recess, betray  
The tender young, bear quick the prize away.  
Tam'd by thy care, the useful brood shall join  
The watery chase, and add their toils to thine ;  
From each close lurking hole shall force away,  
And drive within thy nets the silver prey :  
As the taught hound the timid stag subdues,  
Or o'er the dewy plain the panting hare pursues.

Mr. Edwards, of Little Waltham Hall, Essex, had an otter which always attended him like a dog ; and every afternoon, when the old gentleman slept, the otter regularly stationed itself in his lap : it used to get fish from the ponds in the gardens and grounds near the house ; it had milk also given it, and was at last accidentally killed by a maid servant striking it on the nose, where, it is said, a trifling blow generally proves fatal.

Buffon mentions a tame otter that was kept in 1775 in an abbey at Autun. This was a female, and had been taken extremely young, and reared with milk until two months old, when it was fed with soup, fruits, pulse, meat, fish, &c. which latter, however, it would not eat unless perfectly fresh. It was as tame as a dog, and would come whenever called by its name, and would also play with a dog and cat with which it had been early acquainted, but manifested great animosity against others which approached it. This otter chiefly inhabited a room, and would lie by night on a bed, and during the day on a heap of straw prepared for it : the animal would occasionally plunge its head and fore feet into a vessel of water which always stood near it, and, after shaking itself, go out into the court yard for exercise, and then repose in the sunshine. It appeared to have lost the natural habits of its kind, since being carried one day

## O T T E R

to a pool of water, it seemed afraid and would not go into it, but only wetted its head and feet as in its chamber; and when thrown in to the distance of some feet, it instantly made to the shore, as if in a sort of alarm, and followed readily to the abbey.

But the most curious instance of the otter's being tamed, is that where a person suffered it to follow him with his dogs, with which he used to hunt other otters; and it was remarkable, that so far were the dogs from molesting it, that they would not even hunt an otter whilst it remained with them; upon this account, although the otter was useful in fishing, and in driving trout and other fish towards the nets, the owner was obliged to dispose of it.

According to Goldsmith, the manner of rearing otters to become domestic is to procure them as young as possible, and to carefully feed them at first with small fish and water; as they gain strength, milk is to be mixed with their food, the quantity of their fish provision lessened, and that of vegetables and bread increased, until at length they are fed wholly upon bread, which perfectly agrees with their constitution. The mode of training them to hunt for fish requires both patience and assiduity. They are first taught to fetch in the same manner as dogs are instructed; but not possessing the same sagacity or docility, the operation of teaching them is rendered much more tedious and perplexing. It should be performed by accustoming them to take a truss, made of leather, and stuffed with wool in the shape of a fish, into their mouth, and to drop it when commanded; to run after it when thrown forward, and to bring it to their master. From this, the process is to real fish, which are thrown dead into the water, and which they are taught to fetch to shore. In a short time living fish are made use of instead of dead ones, till at length the education of the animal becomes complete, and he readily obeys his master. Tedious as the process is, the labour is amply repaid, we are told, as an otter, thus taught, will catch fish not only for its own use, but to sustain a whole family.

The otter is found in all parts of Europe, north and north-east of Asia, even as far as Kamschatka, where the natives use the skins to face their garments, or to wrap round those more precious furs of the sables, which are better preserved in otter skins than in any other manner. The otter inhabits none of the Aleutian or Fox Islands, except the easternmost, which are thought to be near the new world. They are sometimes seen as low south as Carolina and Louisiana, but are there very scarce; and otters are not met with farther south. They abound in North America, particularly in Canada, where the most valuable furs of this kind are produced, and where they exceed the European otter in size. The Americans round Hudson's Bay, shoot or trap them for the sake of their skins, which are sent to Europe; and they also eat their flesh.

*The sea otter* is found on the coast of Kamtschatka, and in the adjacent islands, as well as on the opposite coasts of America; but it is confined within a very few degrees of latitude. Its whole length is about four feet, of which the tail occupies thirteen inches. The fur is extremely soft, and of a deep glossy black. The ears are

small and erect, and the whiskers long and white. The legs are short and thick, the hinder toes somewhat resembling those of a seal. The weight of the largest sea otters is from seventy to eighty pounds.

In their manners, these animals are very harmless; and towards their offspring they exhibit an uncommon degree of attachment. They will never desert their young; and will even starve themselves to death on being robbed of them, and strive to breathe their last on the spot where their young have been destroyed. The female produces only a single young one at a time; which she suckles almost a whole year, and till it takes to itself a mate. The sea otters pair and are very constant. They often carry their young between their teeth, and fondle them, frequently flinging them up and catching them again in their paws. Before these can swim, the old ones will take them in their fore feet, and swim about with them upon their backs.

The sea otters swim sometimes on their sides; at other times on their backs, or any upright position. They are very sportive, embrace each other, and seem to kiss.—When attacked, they make no resistance, but endeavour to save themselves by flight: if, however, they are closely pressed, and can perceive no means of escape, they scold and grin like an angry cat. On receiving a blow, they immediately lie on their side, draw up their hind legs together, cover their eyes with their fore paws, and thus seem to prepare themselves for death. But, if they are fortunate enough to escape their pursuer, they deride him as soon as they are safe in the sea, with various diverting tricks: at one time, keeping themselves on end in the water, and jumping over the waves, holding their fore paw over the eyes, as if to shade them from the sun while looking out for their enemy; then lying flat on their back, and stroking their belly; then throwing their young down into the water and fetching them up again. In their escape, they carry the sucklings in their mouth, and drive before them those that are full grown.

The skins of the sea otters are of great value, and have long formed a considerable article of export from Russia. They are sometimes taken with nets, but are more frequently destroyed with clubs and spears. The young animals are said to be delicate eating, and not easily to be distinguished from lambs. The flesh of the old ones is insipid and tough.

**OTTER HUNTING.** This amusement was formerly much in fashion in this country; and as it occurs at a season when the pursuit of the fox and the hare are necessarily abandoned, it offers a sort of apology for field sports when superior diversion is unattainable. As in the pursuit of the otter the hounds are frequently in the water, so the hunting of this animal cannot be undertaken till the severity of the winter and spring has passed away. About a century and a half ago, otter hunting was very common in all those parts of England, where these animals

are to be met with; but it declined so much that twenty years since otter hunting was as nearly extinct as possible: it has since resuscitated, as it were; it is now pursued in various parts of Great Britain; though it is never likely to become general or popular. It is amusing enough to some persons; but the sport is very insipid compared to the chase of the fox, or the pursuit of the hare.

Upon this subject, an old author remarks:—"these otters must be hunted by special dogs, such as are called otter hounds; and also with special instru-

ments, called otter spears\*. When they find themselves wounded with a spear they then come to land, where they fight furiously with the dogs; and except they be first wounded they forsake not the water; for they are not ignorant how safe a refuge the water is unto them, and how unequal a combat they must maintain with men and dogs upon land." This is

not exactly the case; an otter will keep the water as long as he is able, certainly; but as he becomes fatigued by the pursuit, he will quit the water, though he has not been wounded, and endeavour to shelter himself in a sough or drain, or some such subterranean asylum. Somerville thus describes the pursuit of the otter:—

This subtle plunderer of the beaver kind,  
Far off, perhaps, where ancient alders shade  
The deep still pool, within some hollow trunk  
Contrives his wicker couch; where he surveys  
His long purlieu, lord of the stream, and all  
The finny shoals his own.

On the soft sand,  
See there his *seal* impressed! and on that bank  
Behold the glitt'ring spoils! half eaten fish,  
Scales, fins, and bones, the leavings of his feast.  
Fresh, on that yielding flag bed, now once more  
His *seal* I view! O'er yon dank rushy marsh  
The sly *goose-footed* prowler bends his course,  
And seeks the distant shallows. Huntsman, bring  
Thy eager pack, and trail him to his *couch*.  
Hark! the loud peal begins, how greedily  
They snuff the fishy steam, that to each blade  
Rank-scenting clings!  
Now on firm land they range; then in the flood  
They plunge tumultuous; or, through reedy pools,  
Rustling, they work their way: no *holt* escapes  
Their curious search. Yon hollow trunk,  
That with its hoary head uncovered, salutes  
The passing wave, must be the tyrant's fort:  
Mark well! how these impatient climb,  
While others at the foot incessant bay:  
At length his *couch* he leaves, and dives along!  
Th' ascending bubbles mark his gloomy way.

See! there he *vents*!  
The pack plunge headlong, and protended spears  
Menace destruction: Ah! there once more he *vents*!  
See! that bold hound has seized him; down they sink,  
Together lost: see there escap'd he flies  
Half-drown'd, and clambers up the slippery bank  
With ooze and blood distain'd. That spear has pierc'd  
His neck; the crimson waves confess the wound.

Lo! on yon sedgy bank  
He creeps disconsolate; his numerous foes  
Surround him, hounds and men. Pierc'd through and through,  
On pointed spears, they lift him high in air;  
Bid the loud horns  
Proclaim the spoiler's fate—he dies! he dies!

Those who follow otter hunting at present generally go out early in the morning, as soon as the season is sufficiently advanced to enable the dogs to remain in the water without sustaining any injury. The principal reason for going out early

---

\* Otter spears should be barbed; but so contrived that the barbs lie close to the staff or handle till the blow is struck, when they should expand, by means of springs, and thus secure the object.

in the morning is, that as the otter, during the night, frequently strays to some distance from the water side, so the hounds are likely to hit upon the scent under such circumstances, and thus follow him to his *couch*. The sportsmen go on each side of the water, beating the banks and sedges; and if there be an otter in the neighbourhood, his *seal* will most likely be observed on the mud or sand by the edge of the stream: each sportsman should be prepared with an otter spear. Dogs used to the diversion will carefully try, not merely the banks of the river, but will examine every stump or large stone which raises its head above the water, and upon which the *spraints* of the otter will be frequently deposited. The hounds will open in the same manner as harriers will give tongue to a hare, and on this signal, the track of the otter is examined if possible on the banks or water's edge, in order to ascertain which direction he has taken. The pursuit is continued and the otter is generally hunted up to his couch, which he will, however, quit on the approach of the hounds, and he hides himself from view by plunging into the stream; but as he makes way under the water, his track may be frequently observed by the bubbles which form immediately above his course: this serves as a direction to the sportsman. Though the otter will continue for a considerable length of time under water, yet he is forced to the surface to breathe, which, however, he manages with great sagacity; as when he approaches the top of the water for that purpose, he rises perpendicularly, as it were, and merely projects his nose above the surface, and dives again instantly. Thus the *venting* of the animal is scarcely perceptible, and will escape the observation of those unaccustomed to the diversion.

Although the otter is so admirably calculated for swimming and diving; yet he is much sooner fatigued than might be expected; and when he finds himself no longer able to maintain his superiority in the water, he makes directly for the shore. Should he be seized by a dog in the water, he never fails to sink immediately, taking his adversary along with him; the dog is, of course, under the necessity of quitting his hold, and he rises again the moment he can extricate himself from the jaws of his antagonist. The otter, on becoming fatigued, will make for the land, as already observed; and on such occasions he is not easily turned from his purpose. He, how-

ever, thus affords the sportsmen an opportunity of using their spears, and he generally meets his death from the hounds, or perhaps from both, unless he is fortunate enough to make his way into some friendly drain or sough, or into some similar situation, from which it is sometimes found impossible to dislodge him.

The spear is of little, if any service, till the otter approaches the shore, as it is not possible to use it effectively when he vents, though the place should be within the sportsman's reach.

Otters maintain a very fierce and obstinate conflict with the dogs; they bite even more keenly than the fox; they fight to the last gasp, and the male dies without complaining; though the pregnant females, it is asserted, will emit a very shrill squeal.

In 1796, near Bridgnorth, on the river Worse, four otters were killed: one stood three, another four, hours before the hounds, and was scarcely a minute out of sight.

In April, 1804, the otter hounds of Mr. Coleman, of Leominster, killed, in Monkland Mill pond, an otter of extraordinary size: it measured from the nose to the end of the tail, four feet ten inches, and weighed thirty-four pounds and a half.—This animal was supposed to be eight years old, and to have destroyed a ton of fish annually for the last five years.

Otters are easily captured when snow covers the ground accompanied by severe frost: they then collect together and are easily traced: upon the Fobbing marshes in Essex, when the *Fleets* had long been frozen, a party killed nine in one day; and in 1796, a gentleman in Northamptonshire, with the assistance of only a terrier, secured two very large ones out of three, which the dog discovered by the side of a brook.

About twenty-seven years ago, or about the year 1805, as the hounds of the late Mr. Bradshaw, of Halton Hall, near Lancaster, were pursuing an otter in the river Lune, the animal was observed making towards a drain situated near the edge of the water: some of the lower orders were enjoying the diversion, as is very generally the case; and on one of these (a plasterer) observing the manœuvre of the otter, he attempted to prevent the animal from entering the subterraneous retreat just mentioned; in which he succeeded, as well as in forcing the otter again into the water; but it was at some expense, as in the scuffle, the otter bit the end of his thumb

completely off just below the nail; strange as it may appear, the man was unconscious of his loss till he perceived the separated part lying on the sand before him.

It is asserted that otters may be taken in an unbaited trap, but that they reject every kind of bait: the trap must be placed near the otter's landing place, which may be found by examining the edges of the river or pond, either by his spraints, his *seal*, or the remains of fish (for in whatever place he devours his plunder, sufficient marks are uniformly left of his depredations): the trap must be set in, and covered with mud, to prevent his seeing it. The instant the trap strikes, the otter plunges with it into the water, when its weight preventing his rising to the surface, he is drowned. The trap will seldom be drawn more than twenty yards from the spot, and, with a grappling iron, may be soon recovered. If the place where he comes out of the water cannot be discovered, upon the ground, where the remains of the fish are left, a hole should be cut near the edge of the water, and a trap or two placed upon a level with the ground, and covered carefully with moss.

Although the otter rejects all baits in the trap, an instance occurred in August, 1799, in the river Buckland, near Dover, of his taking a line bait. An otter suddenly darted from his holt, and seized the bait of a gentleman trolling for pike, who thought the bait was taken by an overgrown fish, in consequence of the animal's violent struggles. After a long contest, in which the troller displayed much skill, to his great astonishment and that of others upon the spot, he drew the otter to the shore completely exhausted.

For the language or technical terms of this chase, the reader is referred to the article *TERMS in SPORTING*. For the kind of dog calculated for the pursuit of the otter, see the article *HOUND*.

**OVER-DONE.** A horse is said to be over-done, when both his frame and spirits are so exhausted with fatigue and excessive labour, that he sinks down in his stall almost immediately after reaching the stable; where he extends himself at every extremity, giving evident proof of the struggles nature has to encounter, by the bodily inquietude under which he continues distressed for many hours, and sometimes days, before he becomes perfectly recovered. When a horse is reduced to this state, by a too long continuance at slow or steady work, no doubt of recovery

need be entertained with a few days nursing; but if it has been occasioned by a continued and persevering speed with hounds, and a long journey home, danger may be justly apprehended: instances have occurred where internal inflammations have arisen, by which existence has soon been destroyed.

**OVER-REACH.** An over-reach is such injury (either cut or bruise) as is frequently sustained in the heel of a horse's fore-foot, by one of the shoes behind; and this happens during brisk action, in either trot or gallop, where the ground is unexpectedly deep and deceptive: or when a horse is thick in the shoulders, and slow in action before, the hind-quarters are thrown in faster than the fore-legs can get out of the way, by which inactive or sluggish tardiness, the accident is occasioned much oftener than by any other means. It more frequently occurs in hunting than under any other circumstances.

When neglected, or unattended to, if the injury is severe, ill consequences may ensue; the first step to prevent which is, to wash the part well with warm water, slightly impregnated with vinegar: press upon the wound a linen cloth till quite dry, then apply a pledget of lint or tow, well wetted with friar's balsam, or compound tincture of myrrh, covering it securely with a proper bandage, with a view to harden the surface, which is the leading object to be attained. This may be repeated the following day, if necessary, to farther close the mouths of such lacerated vessels as continue to ooze a lymph or ichor. If, however, the cut should be of such magnitude as to resist these means of intentional termination, it must be treated as a wound, and the horse not permitted to encounter work or dirt during its progress and cure. No greasy or unctuous applications should be made, if it can possibly be done without: as the best and most expeditious cure will be obtained by hardening the surface, and preventing a discharge; unless there is a deep and serious destruction of parts, in which case it cannot be obtained but by incarnation.

**OVERTON.** A son of King Fergus, dam by Herod, grand-dam by Snip, great grand-dam own sister to Regulus, was bred by Mr. Hutchinson, and foaled in 1788. At York, in 1792, he won a sweepstakes of 100gs. each, half forfeit, twelve subscribers. The same week he won a 50l. plate, added to a subscription purse, beating Rosalind, Storm, Halbert, and

two others. The next day he beat Halbert a match four miles, for 300gs. giving him a stone. At Doncaster he won the gold cup of 100gs. value; beating Hubby, Rosalind, Smoaker, Gentleman, and Colchis. At York, 1774, he beat Halbert two miles for 200gs. After which he was taken out of training, and became a stallion at Skipton, near York, at ten guineas a mare. He is sire of those famous horses Cockfighter and Rolla.

**OX-FEET**, in a horse, is when the

horn of the hind foot cleaves just in the very middle of the fore-part of the hoof, from the coronet to the shoe; this though not common, is very troublesome, and often makes a horse halt.

**OX-LEGS**. An imperfection in some horses, which, though they have the back sinew of their fore-legs somewhat separate from the bone, yet their sinews are so small and so little set off, that their legs will become round after short labour.

## P

**PACE**. An expression to signify the motion, or progressive action, of a horse, as well as one of the human species. When speaking of a man's pace, it is usual to say, he walks, he runs, or he goes a good pace; which becomes applicable to either, meaning that he is an expeditious walker, a fleet runner, or perhaps both. A horse has a great variety of paces, as a walk, trot, amble, canter, gallop, rattling-gallop, and at speed; some of which many horses have in great perfection, and are exceedingly deficient in others; as for instance, a horse shall be a most excellent trotter, who happens to be a shuffling, execrable, walker; he shall be a gay, airy, light figure in a canter, and wonderfully deceptive in speed. Good gallopers are very frequently bad trotters; and perfection is very difficult to obtain.

**PADDOCK**. In earlier times, a paddock was a space of ground inclosed with a wall or paling of a considerable height, and was used for the purpose of coursing deer with greyhounds. It was a mile long, and a quarter of a mile broad, with the farther end somewhat broader than the other, thus affording an opportunity for a greater number of persons to see the end of the course.

At the narrow end was a small building where the dogs were kept in a state of readiness to run the course. At this place two men were also stationed, one just within the door, with the greyhounds ready in slips; the other without the door, ready to let go the teaser for the purpose of driving off the deer. There were also pens or places for as many deer as were intended to be coursed, attended by several keepers. The deer was forced to run in a course prepared on one side of the paddock close by the wall or paling, and the other side was for the accommodation

of the spectators. Posts were also placed along the course.

1. The law post, which was next the dog house and deer pens, and distant from them about one hundred and sixty yards.

2. The quarter of a mile post.

3. The half mile post.

4. The pinching post.

5. The ditch; which was in lieu of a post, being a place made to relieve the deer from the farther pursuit of the greyhounds; and near this place the judges were seated, who were appointed to decide the wagers.

Every necessary precaution was taken in order to have the dogs fairly slipt; and the owners of the dogs drew lots for the choice of sides, and that next the wall, it seems, was preferred. The dog house being shut, one of the keepers turned out the breathed deer, which had no sooner reached twenty yards, than the teaser was slipped for the purpose of making the deer run. When the deer reached the law post, the dog house door was opened, and the greyhounds slipped. If the deer swerved, before he reached the pinching post, so that his head was judged to be nearer the dog house than the ditch, it was deemed no match, and was to be run again three days afterwards; but if the deer passed the pinching post, and swerved before he reached the ditch, the dog that was nearest the deer was deemed the winner. If the deer ran straight to the end, the dog that first leaped the ditch won the match.

This species of coursing, however, which appears to have been a favourite diversion with Elizabeth, has long since been laid aside; and the word *paddock* at the present time is understood as applying to a small inclosure of pasture having a pale

to protect it ; or to a small tract of land, surrounding, or appertaining to, a rural mansion.

**PALATE.** It is that arch of the mouth, in animals, which is surrounded before by the teeth and gums, and extends backward the whole breadth of the upper part of the mouth, as far as the great opening of the pharynx. This arch is partly hard and immovable, and partly soft and movable. The solid part is formed by the two ossa maxillaria, and the two ossa palati. The soft part lies behind the other. The membrane that lines the palate is full of small glands.

**PALSY.** An abolition of voluntary motion, or of feeling, or, more commonly, of both together. The distinctions made by physicians in this disease are noticed under PARALYSIS.

On the palsy, as it affects the horse, Gibson makes the following remarks. He considers it as having an affinity with the apoplexy, epilepsy, &c. in so far as the nerves are affected in both, but with this difference, that in cases merely convulsive the muscles are strongly contracted by involuntary motions ; whereas, in paralytic disorders, the nerves seem to have lost their sensibility. " In a palsy, (says he) the use of some part of the body, or sometimes, when it derives its origin from the head, the use of one whole side, is taken away, the parts are flaccid and relaxed, without any capacity of motion, and sometimes without sense or feeling, in which respect a palsy affects the body in a manner quite different from an epilepsy. When the palsy seizes one whole side, it is called hemiplegia, and when single parts or members only are effected, it is called paralysis particularis," or *local* palsy. It is known by the use of some particular member in a horse, being totally, or in part, lost ; particularly the limbs, sometimes only one, sometimes more, and especially the hind legs. This kind (Gibson says) is pretty usual, and tremors or shakings sometimes attend in such cases ; but of the many horses he had under his care, he did not notice above two that were seized with the hemiplegia, or that kind of palsy that seizes all the muscles on one side.

Horses that lie out at grass upon cold clay grounds often come up with numbness in their limbs, which they in some degree lose the use of for a season ; but this is not a true palsy, unless the head is also affected, but it is rather a case of rheumatism. In a true palsy there is ge-

nerally a very sily state of the blood, proceeding, for the most part, from high feeding and want of sufficient exercise, from bad provender, from noxious fumes, or from bad air. Sometimes, on the other hand, it arises from too hard work and want of good keep, and not unfrequently from mere old age, which last is the most irremediable of all. When paralytic disorders happen to old horses that have been delicately kept, or, on the contrary, have been in bad keeping and hard worked ; if the disease seizes one whole side, it is scarcely worth our while to attempt a cure. If the palsy seizes only particular parts in old horses, the cure will be difficult, and for the most part only palliative ; for there will always remain somewhat of numbness and insensibility in those parts, which will render such horses of little use. But paralytic symptoms in young horses, proceeding from the other causes we have enumerated, are often removed without much difficulty.

In curing the palsy, Gibson advises the same internal remedies that are made use of in apoplexy, and in convulsive disorders. Here also he thinks it proper to bleed, rowel, and use outward applications, &c. As one of the best of this kind, and what he frequently applied with good success in paralytic numbness, he states the following :

*Stimulating Liniment.*

Take of Oil of turpentine, four ounces ;  
Oil of bays, four ounces ;  
Camphor, rubbed in a mortar,  
one ounce ;  
Oil of amber, three ounces.

Incorporate these together into a liniment ; to which may be added, if needful,

Tincture of cantharides, one ounce. Mix.

Let the affected part be first well rubbed with a woollen cloth, that the liniment may penetrate with more ease ; then take a sufficient quantity and anoint the part with it thoroughly, working it well in the hand, and as fast as the liniment sinks in, renew it. This method we are advised to continue till the numbness goes off, and the horse shews that he has recovered the use of his limbs. " If the numbness and lameness be chiefly in the hind parts, in that case the liniment may be also rubbed into the spine of the back and loins, from whence the principal nerves that go to the limbs derive their origins ; but in this case the tincture of cantharides should be omitted.

Rubbing the parts often is of great use in all such cases, and therefore ought never to be neglected. If the head be affected on one side, so as to draw the horse's mouth awry, the forehead, temple, and cheek on that side ought also to be well rubbed and embrocated with the above liniment, and when this is the case, internals ought not to be laid aside; because we may suppose, with good reason, that the distemper has taken its rise from the head. If a vertigo happens, or if the lameness be universally on one side, but not an universal deprivation of sense and motion, as in the hemiplegia or dead palsy; in the first, viz. in a vertigo, all objects seem to turn round, so that a horse while any sense remains, with the least use of his limbs, will naturally follow the object of his motions. In such a case, all those things that have been recommended for the cure of an apoplexy are also proper, with rowels and outward applications. In the latter, viz. when the lameness is altogether confined to one side, the horse by leaning on the sound side will also turn round to the lame side, having the use of his limbs on the sound side to support him, but not so freely on the other; but as this may happen without a vertigo, the best remedy here is mild purging, and a liberal use of embrocations. A mixture of mustard seed, fresh ground, with camphorated spirits frequently rubbed into the diseased limbs, will be of great use, viz. an ounce of mustard seed to half a pint of the camphorated spirits, and towards the latter end of the cure, opodeldoc may be used with good success. If a lethargy happen, which is not unusual in the distempers of the head, few evacuations will be required; besides, now and then a clyster, with rowels on the neck and under the jaws; and the use of cordials and cephalics, are necessary in all lethargic symptoms, as castor, assafoetida, salt of hartshorn, sal armoniac, and all other volatiles; but this can only be done to horses that are of some value."

Modern writers on the veterinary art have not noticed this disease in their works; and the reason probably is, that the cases of it are rare, and the animals, when so affected, not worth preserving.

**PANNELS OF A SADDLE.** Two cushions, or bolsters, filled with cow, deer, or horse-hair, and placed under the saddle, one on each side, so as to touch the horse's body, and prevent the bows from galling or hurting his back.

**PANTON-SHOE, OR PANTABLE-SHOE.** An old invention, contrived for receiving narrow and hoof-bound heels. Its sponges are much thicker on the inside than on the outside, so that the part which rests upon the horn, or hoof, runs sloping to the end, that the thickness of the inside of the shoe may bear up the heel, and throw or push it to the outside. Panton-shoes are described by Guillet to be proper for horses that have false quarters.

**PARALYSIS.** A palsy; often it signifies a palsy of a particular part. It is also called *catalysis*.

**PARAMOUNT.** The Lord Paramount possesses the privileges of sporting upon certain manors; as, for instance, Sir Thomas Gage claims and exercises a paramount free warren over all the extensive manors in Suffolk, from Ipswich nearly to Newmarket. His keepers invariably go upon each at the beginning of the shooting season and kill a single bird, merely to maintain this singular supremacy.

**PARK.** A park is an extensive tract of ground, inclosed with wall or paling, variegated with wood and water, generally stocked with deer, and generally containing an abundance of game. It becomes a park by the privilege of prescription, or by a grant from the crown. There are many parks belonging to the crown, as well as in the possession of opulent individuals. Windsor Great Park is the largest in the kingdom. It is upon record, that the park of Woodstock was the first in England, and was formed and inclosed about the year 1124. The example was followed by Henry, Earl of Warwick; after which park making might be said to become general throughout the kingdom.

**PARTNER.** There were five famous horses of this name in succession, from Old Partner in 1718, to Little Partner, in 1745. The first was called Croft's; the second, Moore's; the third, Grisewood's; the fourth, Bright's; and the last, Pearson's. Old Partner was got by Jigg, out of a sister to Mixbury; he was a most excellent runner, and produced an astonishing progeny of winners; from whom his blood is ramified through most of the studs in the kingdom. He was sire of Sedbury, Tartar, Cato, Traveller, Badger, Grisewood's Partner, Little John, Larkin's Looby, Duke of Bolton's Little John, Barforth, the Witherington Mare, Vane's Little Partner, Parker's Lady Thigh, Grisewood's Lady Thigh, Lodge's Roan Mare, &c. &c.

## P A R T R I D G E

**PARTRIDGE.** This interesting bird is an inhabitant of all the temperate parts of Europe. The extremes of heat and cold are unfavourable to its propagation; and it flourishes best in cultivated countries, living principally on the labours of the husbandman. In Sweden these birds burrow beneath the snow; and the whole covey crowd together under this shelter to guard against the intense cold. In Greenland the partridge is brown during the summer; but, as soon as winter sets in, it becomes clothed with a thick and warm down, and its exterior assumes the colour of the snows by which it is surrounded. Near the mouth of the river Oi, in Russia, partridges are found in such quantities that the adjacent mountains are crowded with them. These birds have been seen variegated with white and sometimes all white, where the climate could not be supposed to have any influence in this variation, and even among those whose plumage was of the usual colour.

Partridges have ever held a distinguished place at the tables of the luxurious, both in this country and France. We have an old distich—

If the partridge had the woodcock's thigh,  
'Twould be the best bird that e'er did fly.

These birds generally pair early in February; and sometimes after pairing, if the weather be very severe, they collect together again and form into what are called *packs*.

Of partridges there are two kinds, the *grey* and the *red*; the latter is the largest, but the former is what is generally found in this country. The grey partridge differs from the red, inasmuch as it is never seen to perch upon hedges or trees, which is not an uncommon occurrence with the latter.

The partridge is not, like the pheasant, partial to the wild scenes of the forest; she is more the bird of cultivation: where the plough flourishes the partridge best thrives, and is generally discovered gleaning the stubble, or basking upon a sunny bank, and gets into many a difficulty which might have been avoided by feeding more at large; sometimes indeed she is found in the forest, but it is chiefly when hunted by men and dogs from her more favourite haunts.

The male partridge weighs nearly fifteen ounces; though instances have occurred where the male bird has considerably exceeded this weight: in September, 1804, Mr. Fortnam, of Henley, killed a cock partridge on the How Farm, Hambleton, Bucks, which weighed *twenty ounces and a half*! Its girth across the breast was twenty inches and a half. However, the general weight of the cock partridge may be estimated at a trifle below fifteen ounces; while that of the female may be reckoned two ounces less. The length, to the end of the tail, thirteen inches; the eyes hazel; the bill in young birds is brown, in the old bluish white; the legs also are yellowish when young; and, as the birds increase in age, they turn to a dark bluish white. By the bill and the legs, the old and the young birds are easily distinguished; also the last feather of the wing is pointed after the first moult, but in the following year it becomes round, and ever afterwards presents this appearance. The general colour of the

## P A R T R I D G E

plumage is brown and ash, elegantly mixed with black, and each feather is streaked down the middle with buff colour; the chin, cheeks and forehead are tawney, the female paler than the male; under each eye there is a spot, with small warty excrescences; and above and behind the eye towards the ear, is a naked skin of a bright scarlet, which is conspicuous only in old birds: the legs of the male are furnished with a blunt spur or rather knob behind, and the breast with an ill-defined crescent of a deep chesnut colour, which takes place in the beginning of October; this mark rarely appears in the female, though instances have occurred where it has presented itself:-- A Mr. Montague happening to kill nine birds one day, with very little variation as to the bay or chesnut mark on the breast, he was led to open them all, and found that five were females. On carefully examining the plumage, he found that the males could only be known by the superior brightness of colour about the head; which alone, after the first or second year, seems the only certain mark of distinction.

It is asserted, that the partridge will live unmolested, from fifteen to seventeen years; and the writer is inclined, from more than ordinary observation, to believe this position to be tolerably correct; though there are not wanting those who dispute this computation, and maintain that it lives only seven years, and gives over laying in the sixth. Partridges are at their full vigour when two years old.

“According to Ray, there is one third more male than female partridges hatched; and it is well known the old cocks will drive the young off the ground, and afterwards will frequently fight until they kill each other. When too many birds are left these contentions are sure to happen; and the consequence is a scanty produce, for the female is so pursued that she drops her eggs in various places, forming no nest, and perhaps never laying two eggs in the same spot.” This, *which is altogether a mistake*, has been copied from Daniel’s Rural Sports. In the first place, to assert that there is one third more male than female partridges hatched, manifests more of a fanciful theory, than a conclusion drawn from the experience of facts; as, we feel persuaded, no sportsman ever found this to be the case. From something more than thirty years experience, in various parts of England, the writer was never able to observe this preponderance in the number of male birds; yet he has occasionally found what are called *barren pairs* to be male birds; further, in the year 1823, in the month of October, he found a covey of seven birds in the manor of Lathom, in Lancashire, five of which he bagged, and these were five old cocks; and he has reason to believe that the two which escaped were old cocks also. Hence it would seem, that when it so happens that sufficient females are not to be met with, the males form a compact, and continue, if unmolested, to live in harmony till the following spring. But a circumstance of this sort is rarely met with; yet it appears to have originated the idea that “there is one third more male than female partridges hatched.”

As to “the old cocks driving the young off the ground,” this appears to have been a notion taken up from the circumstance of

the domestic cock keeping the young males at a distance from his seraglio ; but it is grossly incorrect, and affords a striking proof of the facility with which error may be propagated, and received as sterling matter of fact. Other writers besides Mr. Daniel promulgated this doctrine through the medium of the press, and it remained uncontradicted till the year 1823 or 1824, when the subject was placed in a proper point of view in the *Annals of Sporting*.—The true state of the case is, that partridges (that is, the coveys) continue to live together in the greatest harmony till the season of love approaches ; when the old female is the first to take alarm : she manifests the utmost jealousy of the young hen birds, which she indiscriminately attacks ; nor does she spare the young cocks, and in this latter part of the contention, she is assisted by her mate, the old cock : thus general confusion ensues, the young birds are scattered abroad to seek mates where they can find them, and the old ones continue undisputed masters of the original domain.

That cock partridges may fight when they meet is highly probable ; but as to the hen dropping her eggs without forming a nest, it is quite ridiculous ; she will have been paired many weeks before the period of laying ; and the cock partridge protects his mate from insult with the most scrupulous attention.

“ So well aware (says Daniel) was the Duke of Kingston of this circumstance (the preponderating number of cock partridges) that he always had the partridges netted upon his manors so soon as paired, and *destroyed all the cocks!*” Such an absurdity needs no comment.

Those who are anxious for abundance of partridges should destroy as many of the old birds as possible, particularly of the old females.

The female lays her eggs, usually from fifteen to eighteen in number, in a rude nest of dry leaves and grass, formed upon the ground : these are of a greenish-grey colour ; and instances are not wanting, where the partridge has laid a greater number of eggs than the usual quantity. In 1793, on a farm occupied by Mr. Pratt, near Terlington in Essex, a partridge's nest was found in a fallow field containing thirty-three eggs ; twenty-three of the eggs were hatched, and the birds went off, and four more of the eggs had live birds in them ; the female covered all the eggs, seven of which, in the centre, were piled in a curious manner. In 1798, a nest was found at Eldborough, Somersetshire, in a wheat field, with twenty-eight eggs. In June, 1801, at Welton Place, Northamptonshire, the seat of Mr. Clarke, a partridge's nest was found in a plantation, in which were deposited thirty-three eggs. It may be remarked, however, that very old or very young birds never lay so many eggs as birds in the meridian vigour of life.

The period of incubation is three weeks ; and so closely do these birds sit on their eggs, particularly when near the time of hatching, that, if we are to believe what has been asserted on the subject, a partridge, with her nest, has been carried in a hat to some distance, and in confinement she has continued her incubation, and there pro-

## P A R T R I D G E

duced her young. Our readers will of course give credit or otherwise to this relation; but certain it is, that the bird will frequently suffer herself to be cut in two with the scythe rather than quit a spot where all her hopes are concentrated.

The young remain in the nest the first day they are hatched, and the next follow the parent birds in search of food, which for several succeeding days consists of those small insects which are found adhering to the blades of grass; they afterwards feed on ants' eggs, larger insects, and blades of grass.

At the season when the partridge is produced, the various species of ants loosen the earth about their habitations. The young birds therefore have only to scrape away the earth, and they can satisfy their hunger without difficulty. A covey that some years ago excited the attention of the Rev. Mr. Gould, gave him an opportunity of remarking the great delight they take in this kind of food. On his turning up a colony of ants, and retiring to some distance, the parent birds conducted their young to the place where they fed very heartily. After a few days they grew very bold, and ventured to eat within twelve or fourteen yards of him. The surrounding grass was high; by which means they could, on the smallest alarm, immediately run out of sight and conceal themselves. The excellence of this food for partridges may be ascertained from those that are bred up under a domestic hen; as, if constantly supplied with ants' eggs and fresh water, they generally arrive at maturity. Along with ants' eggs, it is recommended to give them, at intervals, a mixture of millepedes, or wood lice, and earwigs; as also fresh curds, mixed with lettuce, chick-weed, or groundsel. The fact is, that partridges, when hatched under a domestic hen, are generally too much attended, or, to make use of the homely proverb, killed with kindness. If, on being hatched, the hen was allowed to lead them forth into a garden or a field where plenty of insects and ants' eggs were to be met with, there is little doubt but they would thrive much better than in that state of semi-confinement to which they are generally subjected, and become much more hardy also.

It is said that the partridges which are hatched under a domestic hen retain through life the habit of *calling*, when they hear the chucking of those well known domestic fowls.

The eggs of the partridge are frequently destroyed by crows (the rook as well as the carrion crow) magpies, weasels, stoats, and other animals. It is no uncommon occurrence in the neighbourhood of rookeries, when the nest of a partridge is discovered by these birds, for several of them to dispute the prize with the most determined obstinacy; and we are inclined to think that this mischievous propensity of the rook is not generally known.

The female partridge generally covers her eggs when she leaves the nest; but when they happen to be destroyed, another nest is frequently made, and the female again deposits eggs. The produce of these second hatchings is a puny race; and the individuals seldom survive the dangers to which they are exposed or the severity of the winter.

## P A R T R I D G E

The affection of partridges for their young is peculiarly interesting. Both the parents lead them out to feed: they point out to them the proper places for their food, and assist them in finding it by scratching the ground with their feet. They frequently sit close together, covering their young ones with their wings; and from this situation they are not easily roused. If however, they are disturbed, most persons acquainted with rural affairs know the confusion that ensues. The male gives the first signal of alarm by a peculiar cry of distress; throwing himself, at the same moment, more immediately into the way of danger, in order to mislead the enemy. He flutters along the ground, hanging his wings, and exhibiting every symptom of debility. By this stratagem he seldom fails of so far attracting the attention of the intruder, as to allow the female to conduct the helpless, unfledged brood into some place of security.—“A partridge (says Mr. White, who gives an instance of this instinctive sagacity) came out of a ditch, and ran along shivering with her wings, and crying out as if wounded and unable to get from us. While the dam feigned this distress, a boy who attended me, saw the brood, which was small and unable to fly, run for shelter into an old fox's hole under the bank.” Mr. Markwick relates that as he was once hunting with a young pointer, the dog ran on a brood of very small partridges. The old bird cried, fluttered, and ran tumbling along just before the dog's nose, till she had drawn him to a considerable distance; when she took wing and flew further off, but not out of the field. On this the dog returned nearly to the place where the young ones lay concealed in the grass; which the old bird no sooner perceived than she flew back again, settled just before the dog's nose, and a second time acted the same part, rolling and tumbling about till she drew off his attention from her brood, and thus succeeded in preserving them.

During the period of incubation, the female experiences a considerable moult, the greater part of the feathers of the belly dropping off; these feathers, however, are found in the nest, and there is some reason to believe, are plucked off by the bird for the purpose of covering her eggs during her temporary absences.

The great or general hatch takes place in the early part of June, and many of the birds are able to fly in the beginning of July.

The production of partridges is very uncertain; if the season happens to be dry during the months of May and June, these birds seldom fail to be very abundant: on the contrary, heavy and frequent rains during the period of laying and incubation (and of the latter in particular) make great havock, particularly on the lower grounds. The most critical period is the earlier part of incubation; if the bird has sat for some time on her eggs, and is near the time of hatching, the eggs are less liable to destruction from wet. When the young are excluded they soon acquire strength, and are comparatively speaking, but little liable to injury.

Mr. White, in his History of Selborne, notes, that, after the dry summers of 1740 and 1741, and for several successive years, par-

tridges swarmed to such a degree, that unreasonable sportsmen killed twenty, and sometimes thirty, brace a day.

We are told that “in 1803, so long and excessive was the drought at Oxford, that there were no dews for six weeks just after the hatching season, nor any rain fell for some months ; and Lord Hertford’s keepers at Sudbourn found partridges and pheasants more than a quarter grown, that had their crops so distended for want of moisture, that they suffered themselves to be taken by the hand, and vast numbers were also found dead.” At the first blush of this case, it appears extraordinary ; and it often happens that people give credit to the greatest absurdities, rather than be at the trouble to examine the statement, which, however, as in the present instance, will be frequently found to contain its own condemnation. It must be an extraordinary drought indeed, when the young partridges and young pheasants suffer from want of water, such a one as never occurred in the British islands ; the summer of 1803 is perfectly fresh in the recollection of the writer, and in that part of England where he was at that period situated, no ill effects were visible among the young partridges and young pheasants ; and to talk of the *crops of these birds being distended for want of moisture* savours too much of the burlesque to need a serious refutation ! Yet this very gravely appears in a note at page 77, vol. III. of the Rev. W. Daniel’s Rural Sports.—A dry summer cannot be otherwise than very favourable to the production of both partridges and pheasants.

“A gamekeeper, of Mr. D. Grosvenor, in Dorsetshire, hearing a partridge utter a cry of distress, was attracted by the sound into a piece of oats, when the bird ran round him very much agitated : upon his looking among the corn, he saw a large snake (we are told) in the midst of the infant brood, which he killed ; and perceiving the body of the reptile considerably distended, he opened the belly, when, to his astonishment, two young partridges ran from their horrid prison, and joined their mother ; two others were found in the snake’s stomach quite dead.”

It is no uncommon thing to place partridge eggs under the domestic hen ; when she has sat the regular time, if the young do not appear, the feathers are glued to the inner surface of the shell, owing to the too great heat of the hen ; and in order to remedy the evil, the eggs should be held five or six minutes in water—the moisture will sink through the shell, loosen the feathers, and the young prisoner will then be set free.

The partridge when brought up under a domestic hen seldom forgets its wild origin ; and, as it acquires strength, it continues to estrange itself from the place where it has been reared, until it forsakes it altogether. Amongst the very few instances of partridges remaining tame was that of one which had been reared at the Rev. Mr. Bird’s ; this, long after its full growth, attended the parlour at breakfast and other times, received food from any hand which offered it ; stretched itself before the fire, the warmth of which it seemed much to enjoy ; and at length it fell a victim to the decided foe of all favourite birds, a cat.

## P A R T R I D G E

In 1798, at East Dean, in Sussex, a covey of sixteen partridges were disturbed by some men at plough, and directed their flight across a cliff of the sea over which they continued their course about three hundred yards, when, as if intimidated or affected by the element, the whole were observed to drop into the water: twelve of them were soon afterwards floated to shore by the tide, and picked up by a boy who carried them to East Bourne, where he disposed of his game at nine-pence per head.

In the Leverian Museum were several specimens of the common partridge, the plumage of which offered a striking contrast to the general order of nature:—one was wholly of a pale cream colour; a second had the neck and half the head brownish ash colour, marked with darker streaks, round the neck a white collar, the under parts were also white, the crest like the common partridge, but very pale. There was a specimen also of a dun colour; and another much variegated and very beautiful.

A covey of nine partridges, we are told, were bred upon a farm of the Hon. J. Olmuis, at Sandon, in Essex, four of which were pure white, and three others were mottled.

In 1804, Mr. B. Dudley's keeper killed a partridge that had half the longest feather in each wing of a milk white, and the skin of the central claw of both feet was of the same colour.

In the year 1796, a covey of eight partridges was netted at South Cave, near Market Weighton, four of which were of the most beautiful clear white, three were pied; the other bird escaped.

Amongst the other enemies of the partridge may be enumerated the whole tribe of hawks, and of the sparrow hawk in particular; even the kestrel will frequently pounce upon the partridge; which he has no sooner seized than he plucks the feathers from the back, and begins to devour his victim alive. If, when a partridge has been struck, a person proceeds to the spot immediately, the hawk will release his prize, which will fly away with the feathers stripped off its back; if a minute or two be suffered to elapse, the bird will be unable to fly, and will be in part devoured.

It has been asserted that the carrion crow will strike the partridge; but this the writer is inclined to doubt.

In the mosses (morasses) of Lancashire and the north of England, and in some of the vallies in the Highlands of Scotland, the common partridge is found frequently in very considerable abundance: these birds, however, are somewhat smaller than the partridge which inhabits the more cultivated ground, and also of a darker colour; the former arising from the poverty of its situation, and the latter from the sombrous appearance by which it is constantly surrounded.

The red-legged partridge (red partridge) is also to be found in some parts of England. This bird is larger and more beautiful than the common partridge. The bill and irides are red; the forehead is grey brown; the hind part of the head is rufous brown; the chin and throat white, encircled with black; added to which is a band of white over each eye reaching to the hind part of the head; the fore part of the neck and sides of it are cinereous, with two spots of black on

## P A R T R I D G E

each feather ; the hind part of the neck rufous brown ; the back, wings, and rump, greyish brown ; the breast pale ash colour ; belly, sides, thighs, and vent, rufous ; the sides marked with lunular streaks of white, black, and orange ; quills grey brown, with the outer edges yellowish ; the tail composed of sixteen feathers ; the four middle ones grey brown ; the next on each side, the same, but rufous on the outside ; the five outer ones rufous on both sides ; the legs are red.

This species is abundant in various parts of Europe, Asia, and Africa ; it is numerous in many parts of Italy and France, and also in the islands of Madeira, Jersey, and Guernsey ; and is said to be so plentiful in the isle of Nansio as to be a pest to the inhabitants, who make it a rule to collect as many eggs as possible every year, in order to lessen the breed, which in some seasons have totally eaten up the fruits of the harvest. These eggs which are taken by thousands, are prepared with different sauces, and subsist the islanders for many days.

According to Tournefort, they are so tame in the isle of Scio, that they are driven to seek their food in fields like so many sheep, and that each family entrusts its partridges to the common keeper, who brings them back in the evening, and he calls them together by a whistle, even in the day time. Another account states, that “in the country round Trebizond, a man was seen leading above four thousand partridges ; he marched on the ground while the partridges followed in the air, until he reached a certain camp, three day’s journey from Trebizond ; when he slept, the birds alighted to repose around him, and he could take as many of their number as he pleased.”

We are told that in Provence persons have acquired the art of assembling numerous flocks of partridges, which obey the voice of their conductors with astonishing docility.

The red partridge is of a much more docile and familiar disposition than the grey ; and perhaps it was this species which Willoughby notices when he says “a certain Sussex man had, by his industry, made a covey of partridges so tame, that he drove them before him, upon a wager, out of that county to London, though they were absolutely free and had their wings grown.”

The flesh of these birds is white, and considered by some as better flavoured than that of the grey ; in France they are frequently made into pies and highly esteemed. The red differ from the common partridge in being found in flocks ; whereas, among the latter only those belonging to the same covey congregate ; the red are also observed to perch on trees, &c. which the grey partridge never does.

As far back as the time of Charles II. several pair of these red-legged partridges were turned out about Windsor for the purpose of obtaining a stock ; but they are supposed to have mostly perished, although some of them or their descendants were observed a few years afterwards.

The late Duke of Northumberland procured many in hopes of their increasing upon his manors ; but his hopes were, for the most

part, disappointed. The late Earl of Rochford, as well as the Marquis of Hertford took much more than ordinary pains to establish them in this country; both these noblemen had not only numbers of red-legged partridges brought over from France, but also imported many thousands of their eggs, which were hatched under hens, and set at liberty at a proper age; by which means there were (and perhaps may be still) some years back, plenty of these birds upon the estate of the latter nobleman, near Oxford, in Suffolk. But they did not breed so numerously at St. Osyth (Lord Rochford's); the soil was not so favourable; yet, even here they increased, and, now and then, a covey of them was found at some distance from his Lordship's domains.

A few of these birds were turned out upon Knowsley (belonging to the Earl of Derby) some years ago; but they were not sufficiently protected, and therefore they very soon disappeared.

**PASSADE**, in the manege is a tread, or way, that a horse makes oftener than once upon the same extent of ground, passing and repassing from one end of its length to the other, which cannot be done without changing the hand, or turning and making a demi-tour at each of the extremities of the ground. Hence it comes that there are several sorts of passades, according to the different ways of turning, in order to part, or put on again and return upon the same piste or tread, which is called *closing the passade*.

**PASSAGE**, in the manege. To *passage* a horse, is to make him go upon a walk or trot upon two pistes or treads, between the two heels, and side-ways, so that his hips make a tract parallel to that made by his shoulders. It is but of late that passaging upon a trot has been used, for formerly the word passage signified walking a horse upon two treads behind the two heels.

A horse is passaged upon two straight lines, along a wall or hedge: he is likewise passaged on his own length upon volts, in going sideways upon a circle, round a center, the semi-diameter being above his own length, so that he looks into the volt, and half his shoulders go before the croup. In all passaging, the horse's outward fore leg must cross or lap a great deal over the inward fore leg, at every second time of marking. In a passage on a walk, and that on a trot, the motion of the horse is the same, only one is swifter than the other.

**PASSAGE** upon a straight line, a sort of manege practised but little in France, but very much in Italy, and yet more in Germany. For this they choose a horse that is not fiery, but has a good active

motion, and leading upon a straight line, upon a walk or trot, they teach him to lift two legs together, one before and one behind, in the form of a St. Andrew's cross, and in setting these two to the ground, to raise the other two alternately, and keep them a long while in the air, and that in such a manner, that at every time he gains a foot of ground forwards. The beauty of passaging consists in holding the legs long in the air. The motion of the legs in this passage is the same with that of a walk or trot, for they go in the same order; and the only difference is, that in passaging upon a straight line the legs are kept longer in the air. For a passage there is so much art required, that a horse is two or three years in training to it; and of six horses, it is much if two succeed in it.

**PASTERN OF A HORSE.** The part which intervenes between the joint of that name and the coronet of the hoof. This part should be short, especially in middle-sized horses; because long pasterns are weak, and cannot so well endure labour. Some horses indeed have them so long and flexible, that in walking they almost touch the ground with them, which is a great imperfection, and shews the animal unfit for any sort of fatigue.

**PASTERN-JOINT**, called also the *fetlock* of a horse. The joint above the pastern, which serves for a second knee in each fore leg, and a second ham or hough to each hinder leg. A horse is long or short jointed, according to the shortness or length of the pastern, and the short-jointed is the best.

**PASTES FOR FISHING.** See the article **BAITS**.

**PATENT CARTRIDGE.** I have

used patent cartridges ; not, however, with unqualified satisfaction. They increase the force of the discharge, but are not absolutely free from balling. Further, after a few shots, they become troublesome in loading, from not going easily down the barrel. Cartridges somewhat similar were used in the East Indies long before their introduction into this country. They are used, I believe, by pigeon-shooters ; but neither the wire nor what is termed the expanding car-

tridge are worth the notice of the sportsman.

PATTEN-SHOE was a shoe formerly used with lame horses ; but seems now to be banished from practice. This shoe was constructed with a ring, circular, or nearly oval, at the bottom, which being fixed upon the sound foot, its intentional use was to compel the horse in all injuries to stand upon the lame leg, that a contraction of the muscular parts might be prevented.

PEACOCK. This beautiful bird, though not met with in a state of nature in this country, nevertheless merits notice in this place, as it affords amusement in the East Indies to the shooting sportsmen of that part of the world, and particularly to the British residents.

The peacock, by the common people of Italy, is said to have the plumage of an angel, the voice of the devil, and the guts of a thief. In fact, each of these qualities mark pretty well the nature of this extraordinary bird. When it appears with its tail expanded, there is none of the feathered creation can vie with it in beauty ; yet the horrid scream of its voice serves to abate the pleasure we find from viewing it ; and, still more, its insatiable gluttony, and spirit of depredation, make it one of the most noxious domestics that man has taken under his protection.

Our first peacocks were brought from the East Indies, where they are still found in great abundance in a wild state. So beautiful a bird, and one esteemed such a delicacy at the tables of the luxurious, could not be permitted to remain long at liberty in its native retreats. Hence, so early as the days of Solomon, we find in his navy, among the articles imported from the East, apes and peacock. *Ælian* relates that they were brought into Greece from some barbarous country, and were held in such high esteem among them, that a male and female were valued at above thirty pounds of our money. We are told also that when Alexander was in India, he found them flying wild in vast numbers on the banks of the river Hyarotis, and was so struck with their beauty that he laid a severe fine and punishment on all who should kill or disturb them. Nor are we to be surprised at this, as the Greeks were so much struck with the beauty of this bird, when first brought among them, that every person paid a fixed price for seeing it ; and several people came to Athens from Lacedæmon and Thessaly, purely to satisfy their curiosity.

It was probably first introduced into the West merely on account of its beauty ; but mankind, from contemplating its figure, soon came to think of serving it up for a different entertainment. *Aufidius Hurco* stands charged by *Pliny* with being the first who fattened up the peacock for the feast of the luxurious. *Hortensius*, the orator, was the first who served them up at an entertainment at Rome ; and from that time they were considered as one of the greatest ornaments of every feast ; and the Romans spoke of the peacock as being the first of viands.

In the time of Francis I. however, we find that it was a custom to

BIRDS, *Plate VII.*

PEACOCK, *p.* 594.

RUFF AND REEVE, *p.* 752.

## P E A C O C K

serve up peacocks to the tables of the great, with an intention not to be eaten, but only to be seen. Their manner was to strip off the skin ; and then preparing the body with the warmest spices, they covered it up again in its former skin ; with all its plumage in full display, and no way injured by the preparation. The bird, thus prepared, was often preserved for many years without corrupting ; and it is asserted of the peacock's flesh that it keeps longer unputrified than that of any other animal.

Like other birds of the poultry kind, the peacock feeds upon insects and corn, but its chief predilection is for barley. But as it is a very proud and fickle bird there is scarcely any food that it will not at times covet and pursue. In the indulgence of these capricious pursuits, walls cannot easily confine it ; it strips the tops of houses of their tiles or thatch ; it lays waste the labours of the gardener, roots up his choicest seeds, and nips his favourite flowers in the bud. Thus its beauty but ill recompenses for the mischief it occasions : and many of the more homely-looking fowls are very deservedly preferred before it.

Nor is the peacock less a debauchee in its affections than a glutton in its appetites. He is still more salacious than even the cock ; and though not possessed of the same vigour, yet burns with more immoderate desire.

The peahen seldom lays above five or six eggs in this climate before she sits.—Aristotle describes her as laying twelve ; and it is probable, that, in her native climate, she may be thus prolific ; since it is certain, that, in the forests where they breed naturally, they are numerous beyond expression. The peacock lives about twenty years ; and it is not till the third year that it acquires that beautiful and variegated plumage that adorns its tail.

“In the kingdom of Cambaya (says Taverner) near the city of Baroch, whole flocks of them are seen in the fields. They are very shy, however, and it is impossible to come near them. They run off swifter than the partridge ; and hide themselves in the thickets where it is impossible to find them. They perch by night upon trees ; and the fowler often approaches them at that season with a kind of banner, on which a peacock is painted to the life on either side. A lighted torch is fixed on the top of this decoy ; and the peacock, when disturbed, flies to what it takes for another, and is thus caught in a noose prepared for that purpose.”

There are varieties of this bird, some of which are white, others crested ; that which is called the *peacock of Thibet*, is the most beautiful of the feathered creation, containing, in its plumage all the most vivid colours, red, blue, yellow, and green, disposed in an almost artificial order, as if merely to please the eye of the beholder.

Peacocks, or rather pea-fowl, are very abundant in India, and afford amusement to the British residents in that part of the world with the dog and gun. They are seldom, however, found at any distance from the jungle, into which a wounded bird will either fly or run if possible ; therefore, unless they are killed or completely disabled, they are lost to the sportsman, as few will be hardy enough

to venture after a wounded bird into the jungle, where the lurking tiger lies ready to spring upon his victim.

horse, a point much regarded by sportsmen.

PEDIGREE. The genealogy of a

PEEWIT. See PLOVERS.

PERCH have one peculiarity, which is contrary to the nature of all fish of prey in fresh water (and they are so voracious as to attack their own kind,) that they are gregarious, swimming in shoals. The body of the perch is deep, the scales very rough, the back much arched, and the side line approaches near to it; the irides are golden; the teeth small, disposed in the jaws and on the roof of the mouth, which is large; the edges of the covers of the gills serrated, on the lower end of the largest, is a sharp spine, and the head is said to consist of no fewer than eighty bones: the colours of the perch are beautiful, the back and part of the sides being of a deep green, marked with broad black bars pointing downwards; the belly is white, tinged with red; the ventral fins of a rich scarlet, the anal fins and tail (which is a little forked) of the same colour, but rather paler.

This fish is a slow grower, and seldom with us is caught of an extraordinary bigness; in Lapland it arrives at a size far superior, for Schæffer asserts, "that there is a dried head of a perch preserved in the church of Luehlah, which from the top to the under jaw is above two hands broad." The largest ever heard of in this country was taken in the Serpentine river, in Hyde Park, which weighed nine pounds; but that weight is very uncommon.

One of eight pounds was caught in Dagenham Breach by Mr. Carter; and in the Angler's Sure Guide is noticed the portrait of one, taken at Oxford, twenty-nine inches long, and deep in proportion. Where the perch are considered to run large, their general length is from about ten to sixteen inches.

It is a common notion that the pike will not attack the perch, on account of the spinal fins which are erected at the approach of the former. This may be true with respect to large perch; but the compiler has had ample proof in many waters of the small ones being a most tempting bait for the pike, especially in Whittlesea Mere, where the trimmers baited with that fish were always most successful.

The perch is tenacious of life; and it has been said, they have survived a journey of sixty miles packed in dry straw.

Perch are found as well in clear, swift rivers, with pebbly, gravelly bottoms, as in those of sandy and clayey soils; they are fond of water moderately deep, and frequent holes by the sides of, or near to, gentle streams, where there is an eddy; the hollows under banks, among weeds and roots of trees, piles of bridges, or in ditches and the back streams, that have communication with the larger river. Ponds which are fed by a brook or rivulet perch thrive very fast in; their haunts are there chiefly deep holes, between weeds or stumps of trees, or on gravelly scours.

Perch spawn, according to the opinion of many, in February or March; certainly some of them spawn in May. In the Elements of

## P E R C H

Natural History it is said, "in April or May, while rubbing itself on some sharp body, to deposit its ova, sometimes to the amount of 280,000 (this number is vastly beyond the calculation in Mr. Harmer's Tables, but this fish weighed two pounds and three-quarters, and the spawn alone seven ounces, a weight nearly as heavy as the whole fish described by Mr. H.) it lives mostly upon the smaller fishes, and in its turn is preyed upon by the pike, but more by the eel, and likewise by ducks."

The perch affords the angler great diversion, and not only the baits are various, but the modes of using them. Of worms, the best kinds are small lob-worms which have no knot, brandlings, red dung-hills, or those found in rotten tan, all well scoured; the hook may be varied from No. 2 to 6, being well whipt to a strong silkworm-gut, with a shot or two a foot from it: put the point of the hook in at the head of the worm, out again a little lower than the middle, pushing it above the shank of the hook upon the gut; take a smaller one, beginning the same way, and bring its head up to the middle of the shank only, then draw the first worm down to the head of the latter, so that the tails may hang one above the other; keeping the point of the hook well covered. This is the most enticing method that can be adopted in worm-fishing; use a small cork float, to keep the bait at six or twelve inches from the bottom, or sometimes about mid-water: in angling near the bottom, raise the bait very frequently from thence almost to the surface, letting it gradually fall again. Should a good shoal be met with, they are so greedy that they may be all caught, unless one escapes that has felt the hook; then all is over, the fish that has been hooked becomes restless, and soon occasions the whole shoal to leave the place. Two or three rods may be employed, as they require time to gorge sufficient to allow the angler to be prepared to strike them. To draw these fish together, three or four balls of stiff clay should be procured, and holes made in them; one end of a lob-worm should be put into each hole, and the clay closed fast upon them, and these (a yard or two distant from each other) thrown into the water where it is proposed to angle; the worms being alive in the balls, by their moving or twisting about, tempt the fish to feed upon them: but the angler's worms being of a superior kind, they will, on sight of them, leave those on the clay, and seize with eagerness the others: not perch only, but many sorts of fish are collected by this ground-bait; so that at times the gentle and other baits may be tried.

In a bad day, when the perch will not be thus brought on feed, take off the float, and extend the line as long as the rod will throw the bait out (which should be worms) without injuring it; cast it in all directions, sometimes across, at others up or down the water, drawing the bait towards you, and playing with a similar motion as in spinning a minnow; try not long in one spot; when a fish bites, slacken the line, and give time before striking: this often succeeds in bad weather, when all other methods fail, but more especially in a rough southerly or westerly wind.

If the angler roves with a minnow, let it be alive, (and by putting

them as soon as caught into his minnow-kettle, and placing them in the stream, they are easily preserved) and the hook stuck in under the back fin, or through the upper lip; let the minnow swim in mid-water, or rather lower; use a cork float of a size that he cannot sink it under water, with a few shot, about nine inches from the hook, to keep him down, or, when tired, he will rise to the surface. When using the frog, put the hook through the skin of its back, and it will swim easier than if the hook was thrust through the skin of its hind legs; recollect to keep this bait as far from the shore as possible, for he will constantly be making to it: always give line enough at a bite, to let the perch gorge. May and June are the best months, as the perch are then prowling in search of the young fry of dace, roach, and other fish. Where pike are suspected to haunt, the hook should be fixed to gimp; as, in this way of fishing, they will take the bait as well as the perch.

Some use minnows, as in the dead snap for pike, with three fine gut twisted together, or a piece of small gimp, to which the hook is tied; the baiting needle must be shorter, the wire of it small, and the minnow exactly baited as a dace for pike. By this mode there is a greater certainty of hooking the fish, as all fish of prey seize their food by the middle: when the hooks are thus placed, they are more sure than the common method with a large hook, and a smaller above it; the way of using the latter is, to a hook, No. 3, tie a link of gut, or fine gimp, at about three quarters of an inch above it; tie a hook, No 9, (there are small ones called lip-hooks, adapted to this sole purpose of keeping the minnow in a proper position) join this link, which should be eight inches long, to another, by a small swivel closed at both ends, fastening a small lead weight (shaped like that directed to be used in the dead snap for pike) about an inch above the swivel; these swivels are to be fastened to the links with fine double silk well waxed, and the end of the upper link formed into a noose, (secured also with waxed silk) to fix it to the line; the point of the large hook is to be put in at the shoulder of the minnow, and down as far as the bend of the hook will permit, bringing the point out so that the tail may be a little curved with the bend of the hook, which will cause it to spin better: fasten the head with a small hook, by running it through the middle of the bottom, and out at the top of the upper, jaw. The only recommendation to this plan, is the readiness of baiting the minnow; the other being unquestionably the best for hooking the fish which bite at it.

Other baits for the perch, are loaches, sticklebacks, with the spines cut off, miller's thumbs, horse beans boiled (after the place has been well baited with them, put one at a time on the hook) cad-bait, bobs, and gentles.

Although generally termed a bold biter, the perch is extremely abstemious in winter, and scarcely ever bites at that season, but in the middle of a warm sun-shiny day: he bites best in the latter part of the spring, from seven to eleven in the forenoon, and from two to six in the afternoon, except in hot and bright weather, and then from sun-rise to six in the morning, and in the eve from six to sun-set. If

a day be cool and cloudy, with a ruffling south wind, perch will bite during the whole of it. In clear water, sometimes a dozen or more of perch have been observed in a deep hole, sheltered by trees or bushes; by using fine tackle, and a well scoured worm, the angler may see them strive which shall first seize it, until the whole shoal have been caught. The perch may be angled for and taken until the end of September, and indeed at particular times all the year round; but the preferable season is from the beginning of May to the middle of July.

In a lake called Llyn Raithlyn, in Merionethshire, is a very singular variety of perch; the lower part of the back bone, next the tail, is strangely distorted; in colour, and in other respects, it resembles the common kind, which are as numerous in the lake as these deformed fish; of which latter some have been taken of nearly two pounds weight. They are not, says Mr. Pennant, peculiar to this water, for Linnaeus notices a similar variety found in small lakes near Fahlun, in his own country; and Mr. P. also heard it was to be met with in the Thames, near Marlow. In Sweden, the country people imagined this alteration in the shape of the perch to be occasioned by the quality of the water in those lakes, being impregnated with some mineral salt, especially as they are situated near the largest copper mine in Europe; but there is no copper mine near Llyn Raithlyn or the river Elynion, where trout are found crooked in the same manner as the perch, although from the taper make of the former, the curve does not appear so strongly as in the latter.

The Honourable Daines Barrington, in a letter to Dr. Watson, remarks, that these fish in Llyn Raithlyn (of which he had received specimens, as he desired, very small, for the convenience of preserving them in spirits) were not only crooked near the tail, but for about one third of the whole length of their body; and had likewise a very remarkable protuberance on each side, which he had opened with a knife, but it did not materially differ from other parts of the flesh, and when dressed, there was nothing in the taste to distinguish them from the common perch.

At Malham Water, not far from Settle in Yorkshire, the perch grow to five pounds weight and upwards: and this remarkable circumstance attends them, that these large fish are all blind of one or both eyes.

Perch will strike a flew net freely; the rougher the wind, if from the south or west, the more they range in quest of food: in a north or east wind they stir as little as possible from their holds: success with either net or line is not to be fairly expected with the wind from these quarters.

**PERCUSSION POWDER.** Percussion powder differs from common gunpowder inasmuch as it ignites with a blow, or, in other words, with excessive friction; and contains so great a quantity of elastic fluid, that, on explosion, its expansive force, compared with gunpowder, is at least in the proportion of twenty to one, perhaps much greater.

How long the composition of percussion powder has been known amongst able experimental chemists, I will not pretend to decide; but its discovery is not of a very recent date; and some years ago an attempt, which was made in France, to introduce oxymuriate of potass into the manufacture of gunpowder, was attended with fatal effects.

Percussion powder may be made of oxymuriate of potass, sulphur, and charcoal. I tried a number of experiments on the above ingredients, and, after varying the proportion of each in every possible way, it appeared that the following were the best calculated for the purpose:—

Oxymuriate of potass, nine parts;  
Sulphur, one part and a half;  
Charcoal, one part.

But I was surprised at the variations which might be made in the proportions or parts, without any perceptible difference in the result. One effect, however, I uniformly found, namely, excessive corrosion; and those who have been in the habit of using Forsyth's method are very well aware of the urgent necessity of cleaning the lock immediately after using, in order to prevent the destruction of the percussion apparatus, as one night only would produce a degree of rust scarcely credible by those unacquainted with the nature of oxymuriate of potass. Whatever advantages were to be derived from the use of percussion priming, they were certainly much lessened by the trouble of cleaning, as the feculent matter deposited was much greater in quantity, and adhered with more obstinate tenacity, than that which is produced by the discharge of gunpowder; I was, therefore, pleased to find that the following, in a great degree, remedied the evil:—

Oxymuriate of potass, one ounce;

Antimony, one ounce;

well pulverized, and made into a paste with spirit of wine in which a little resin or gum mastic has been dissolved: it may be granulated by forcing it through a hair sieve when it is nearly dry, and will be fit for use without further trouble. If spirit of wine be not at hand, I believe vinegar, without either rosin or gum mastic, will answer the purpose. Percussion powder is strong according to the force with which it is struck; if ignited by slow friction, the explosion is weak.

In making percussion powder, I would wish to impress upon the mind of the sportsman the strong necessity of caution in the preparation. The oxymuriate of potass should be pulverized separately upon a smooth stone (or a smooth hard board will answer the purpose), but with a wooden muller, as it would be apt to explode if rubbed with a heavy stone muller, particularly if great velocity was used. It is of no consequence how the antimony is reduced to powder; it may, indeed, be purchased at the druggist's in

powder, but seldom sufficiently fine for the purpose. However, when the oxymuriate of potass and the antimony are ground so as to be impalpable, they may be mixed with a pallet-knife (adding the spirit of wine or vinegar) and forced through the sieve as before mentioned. I have generally used spirit of wine in which a little resin has been dissolved, in preference to vinegar, because I am of opinion, that powder thus made up is not so apt to imbibe moisture. Eau de Cologne is supposed to be preferable to spirit of wine; but the difference when using the powder is imperceptible. Excessive friction from iron or steel, or other very hard substances, would, no doubt, ignite this powder; but it would be a difficult matter, however hard it might be rubbed between two pieces of wood, to produce combustion.

It has been before observed, that if sulphur and charcoal are used with oxymuriate of potass, a great excess of corrosion will result from the explosion: but antimony corrects or neutralizes the acidity or corrosive quality of the oxymuriate of potass, and renders the powder less injurious, in regard to rust, than even common gunpowder; while it is, at the same time, in every other respect, superior.—An ounce of oxymuriate of potass, and an ounce of antimony, will make, I should suppose, about 10,000 primings. It may be mixed up in the manner before described in a few minutes, without the least danger. The oxymuriate of potass, when bought at the chemist's by single ounces, costs two shillings an ounce, and, I have no doubt, could be sold, with a reasonable profit, for much less; an ounce of antimony will cost a penny: so that, including the spirit of wine, the expense of two ounces of priming powder will amount to little more than two shillings. When the superior strength of percussion powder is taken into consideration, it is much cheaper than gunpowder; but, how far it is susceptible of application to fire arms beyond the priming, has not been determined; yet the present forms of the breeches of guns are not calculated to admit of its use for the charge, on account of the very small quantity which would be admissible for that purpose. Nor, for the purposes of safety, would it be advisable to carry percussion powder in a spring-top flask, unless the springs were altogether made of something much softer than steel. If the sportsman thinks proper to carry percussion powder into the

field, independently of what he has already prepared for priming, I know of nothing more safe or more convenient than a small wooden box.

From the following paragraph, it would appear that gunpowder may be ignited by percussion:—"From experiments made in the laboratory of the Royal Institution, it has been found, that if gunpowder be mixed with pulverized glass, felspar, and particularly with harder substances, it may be inflamed by being struck violently on an anvil, though faced with copper, and struck with a copper hammer."

For military purposes, I should think percussion powder, for priming at least, an object of the first importance. However, as far as relates to the sportsman, the manufacturing of percussion powder by his own hands, or under his immediate inspection, is by no means necessary, since the copper caps, properly primed, may be purchased at any gunsmith's at a reasonable price. In the first instance, the component parts of percussion powder were a matter highly interesting to the philosophical and inquisitive sportsman: but since the manufacturing of this article has become so general, and attained a degree of satisfactory perfection, it may be safely confined to those whose business it is to supply the sportsman with this highly important improvement in the discharge of the fowling-piece.

PERCUSSION PRINCIPLE COMPARED WITH THE FLINT LOCK. We extract the following from Johnson's Shooter's Companion.—"This part of my subject very consistently brings me to the examination of some crude notions of Ezekiel Baker, which, though they have been committed to press with a studied affectation of candour and plausibility, are by no means consistent with that philosophic simplicity which a slight glance at his "*Remarks on Rifle Guns*" might induce a superficial observer to suppose constituted the very essence of his publication. 'On the 19th of February (says Ezekiel Baker) I proved a pair of double barrels on the percussion principle; and, though one pair had been proved at the Company of Gun Makers' proof-house, both in their single and double state—had stood the proof, and were marked as sound barrels—had been afterwards proved by me in the usual manner, both regular and water-proof; yet, when I proved them by the percussion principle, both barrels bulged, were much shivered, and were, consequently, spoiled.

'The other pair had undergone the strictest proof at my proof house, (continues the writer,) and such as would be generally considered sufficient to justify the strongest recommendation for safety; yet, on trying them by the detonating principle, the result was the same—both barrels were seriously injured.

'Feb. 22, 1823.—I have this day tried another pair of barrels (says Baker) which had undergone the regular proof, and which I had absolutely fitted to the stock for sale, by specific order—both barrels failed.

'Thus, for the purpose of satisfying numerous enquiries, for my own satisfaction, and on the principle of endeavouring to prevent the fatal accidents which are daily occurring, have I, at some expense, made these trials, in the hope of conducing to perfection in the use of rifles and fowling-pieces; but, above all, with an anxious desire to avert the dreadful calamities which may arise from pursuing a favourite recreation.

'These barrels had stood every proof which is usually considered safe; and yet, from the suddenness with which the powder is ignited by the detonating principle, all the barrels failed. Consequently, the result of these experiments convinces me, beyond any theoretical views entertained by others, that the proof of double barrels with the percussion locks can only be satisfactorily proved by the detonating principle. Every other proof, however it may appear to pass the ordeal of safety, is not a sufficient guarantee: and I can only add to my former injunctions, that no gentleman should venture to use the double-barrel with the percussion lock, without having it first proved by its own strength and power.'

Now, what does all this prove? Why, that to charge a gun, fitted up on the detonating or percussion principle, not so large a quantity of gunpowder is requisite; or, in other words, that, from the instantaneous ignition of the gunpowder in the barrel, a less quantity of it will produce the requisite force; nor could Ezekiel Baker have brought forward more incontestible proofs of the decided superiority of the percussion principle, than what he has adduced in a tone of condemnation; for he clearly manifests the greater force with which the shot must be driven when the gun is discharged in the manner just mentioned. He tells us the barrels which he tried 'had undergone the strictest proof at his proof-house, and such as

would be generally considered sufficient to justify the strongest recommendation of safety, yet, on trying them by the detonating principle, both barrels were seriously injured.' Thus, then, when the quantity of powder used in proving barrels is ignited by percussion priming, the force is so much increased, as to 'seriously injure,' if not burst, the barrels; and that, too, even after the said barrels had withstood the severest test of proof by water. It hence results, not only that the principle in question is the best calculated for the purposes of the sportsman, but advisable, above all, in the proof of barrels, as affording the best possible test of the strength of the metal, and, consequently, of the safety of those whose business or inclination induces them to use fire-arms.

Mr. Baker also enumerates what he calls the *advantages* and *disadvantages* of the percussion principle.—

'*Advantages.*—By the detonating or percussion principle, the whole of the powder is fired instantaneously; but the very quickness with which the powder is burnt, in my opinion, lessens its general effect; and I am satisfied more execution will be done at an equal distance with the charge from the common flint. Indeed, I have proved this fact, by many experiments from the same barrel.—In rain or snow, the percussion lock will act, from its detonating power, more correctly than the common flint lock; and this, by sportsmen, is considered its greatest and, I must confess it appears to me, its only advantage.

'*Disadvantages.*—Although the powder in the barrel is fired much quicker; the barrel is necessarily more strained; and to this cause I attribute most of the accidents arising from the bursting of barrels: as it stands to reason the suddenness of the ignition requires a greater thickness at the breech, and, consequently, that the barrel must either bulge or break, if it be not of a sufficient thickness to resist the power of the charge. This observation applies more particularly to double-barrelled guns when fired by percussion: and in all descriptions, the recoil to the shoulder is more powerful. If, on the other hand, I reduce the quantity of powder to prevent the chance of bursting, or to lessen the force of the recoil, then I can decide, from repeated experiments, that the same charge from the common flint lock, is more effective, and throws the shot with more strength, and in greater quantity, to the object; and I am

corroborated in this result by the practical test of many scientific sportsmen. I may be allowed to add, that, in my judgment, the percussion lock may mend a bad fowling-piece; but I never found it of peculiar advantage to a good one.'

To me, I must confess, it appears most extraordinary that Mr. Baker should have made these remarks after what he has said about the *proof of barrels*; it is 'passing strange,' also, that, while he admits the superior force or strength with which the shot is thrown by the percussion or detonating principle, he, nevertheless, says he is 'satisfied more execution will be done at an equal distance with flint.' And when he follows up this assertion by observing, 'indeed I have proved this fact by many experiments from the same barrel,' I can only say, that his experiments on this subject afford very different results from those of many other persons. Further, I maintain, without the fear of demonstrative contradiction, that it is not possible to make any flint lock, by any means whatever, shoot so strongly, or drive the shot with so much force, or so truly, as by the percussion principle.

As to the barrel being 'necessarily more strained,' this must always happen where the pressure or force is greater. If the same charge of powder be fired by percussion as with the flint lock, the force of the former will be found to exceed that of the latter to such a degree as would not fail to astonish those who had never made the experiment.

In fact, to sum up the whole, it may be justly remarked, that, by the percussion or detonating principle, a less quantity of gunpowder will produce the requisite force; and, from the very extraordinary rapidity with which the ignition of the charge of gunpowder in the barrel is accomplished, and from the effectual stream of fire which is driven into it, the discharge is produced much quicker, and consequently much better, than it is possible to effect by the flint lock.

Such, indeed, is the difference of the two plans, or principles, that those who have used the percussion lock would suppose the best flint lock to hang fire, should one of these afterwards happen to fall into their hands.

There has not, I believe, ever occurred a single instance where a person, having used a percussion lock, has laid it aside and recurred to the flint lock, at least, since the great improvements that have

taken place in the manufacture of the percussion powder, and also in the modes of applying it to the fowling-piece, and more particularly since the introduction of the copper cap.\*

I feel a perfect conviction that there are very few sportsmen (I am inclined to think not one who has used it) who will not readily admit the decided superiority of the percussion principle, either as regards the weather, quickness, or effect:—indeed, it appears to me a self-evident fact, that as, by the detonating plan, the shot is driven quicker and stronger (the latter being the consequence of the former), it must be rendered more effectual than where, by a slower process, as in the flint lock, it is not possible it can reach the object with the same force or the same precision. Mr. Baker admits that the discharge of the percussion gun is more instantaneous and much stronger; and yet, by a strange anomaly, declares, that he is ‘*satisfied more execution will be done at an equal distance with the charge from the common flint !!!*’

When the percussion lock was first introduced, I was with difficulty prevailed upon to try it, as I could not conceive any improvement necessary or possible, believing that the fowling-piece had already attained the summit of perfection: but I was soon compelled to admit its great superiority. I resolved to adopt it; several plans were submitted to my inspection, Forsyth’s among the rest; I chose a sort of lateral magazine, which I was induced to believe possessed every possible advantage; and I must admit it acted uncommonly well in the gunsmith’s shop. With a gun fitted up accordingly, I took the field on the first of September; my dogs stood, and I walked deliberately up to the point; the birds rose and my gun missed fire! it missed fire seven times successively! I sat down with as much philo-

sophy as I could muster, and endeavoured to ascertain the cause of these vexatious miscarriages: at length, I was willing to suppose I had rectified the error, and that I might depend upon my gun going. In the latter I was not mistaken, for, on next pulling the trigger, the piece was not only discharged, but the lock and part of the stock driven off into the bargain! I afterwards tried several other modes; and though one or two plans answered tolerably well, yet I met with no contrivance whatever which gave me complete satisfaction till the *copper-cap* fell under my observation. This I have used for many successive seasons, and, as far as I am able to form an opinion, it is much preferable to every other mode.

From more than ordinary practice and attention, I feel no hesitation in stating, that, by the percussion principle, the charge of powder in the barrel is ignited more instantaneously, and the combustion is more complete; the shot is, consequently, thrown or driven to the mark with much greater force, precision and effect; and this, too, will be accomplished with two-thirds of the common charge of gunpowder. It will be found, upon enquiry, (and I have repeatedly tried the experiment,) that whenever the percussion apparatus is applied to the fowling-piece, (supposing one which had before been fitted up with the flint lock, and of indisputable merit,) the charge of powder may be reduced one-third, with advantage. Mr. Baker says, that the percussion guns should be made very strong at the breech-end; in this, I not only agree with him, but I strongly advise every gun to be so made, and the percussion gun, perhaps, in particular; I would also advise every sportsman, for the purpose of safety, not to be afraid of carrying an extra ounce or two, and he may rely upon it, his gun will shoot the better for it; though, as long as the breech-end is sufficiently strong, I am of opinion it matters not how thinly it tapers to the muzzle. The discharge of a light gun is uniformly attended with a very considerable recoil, and seldom shoots well.

In accidental or chance shots, and also in woodcock or cover shooting, the percussion is preferable to the flint gun, from the superior rapidity of its discharge. In wet weather, and particularly amongst the drizzly rain on the grouse mountains, the former will be found much more effective, particularly since copper caps are made *water-proof*, and can thus be had, I

---

\* The magazine of Forsyth was the first plan which introduced the application of percussion priming to the notice of the sportsman. This required more than ordinary attention, and yet became frequently out of order; various other magazines and plans were introduced, all objectionable; and, as they were attended with danger, and could never be depended on, so some of those persons who plagued themselves for sometime with these ill-digested applications, became wearied with disappointment, and again made use of the old flint lock.

believe, at any gun-smiths. I am not aware, indeed, of any quality in the flint lock which the percussion does not possess in a higher degree; while less is to be apprehended from it on the score of accidental danger.

On the subject of the percussion principle, compared with the flint lock, I was surprised at reading the following passage in Colonel Hawker's 'Instructions,' &c. He says a detonator 'goes *quicker*, though not *stronger*!' This expression must surely have been made without due consideration, since it is clearly a self-evident fact, that the quicker the discharge, the stronger the shot must be driven. Or, supposing a cannon-ball to fly through the air at the rate of two miles in two seconds, and another to occupy six seconds in passing the same distance, can there be a doubt which of the balls will strike the object with the greater force? Further, I think no person will be hardy enough to deny, that, generally speaking, projectile force must entirely depend upon its velocity."

**PERSPIRATION.** Without a free perspiration no animal can continue in a healthy state. The matter of perspiration is separated through the skin, and also from the lungs, it is simply aqueous, containing only a small portion of salt.

Perspiration is of two kinds, viz. that which is imperceptibly transuding, and is called insensible; the other, which is sensible, is called sweat. It has been supposed that different vessels throw off these discharges, but that is not the truth; the same vessels which throw out the insensible, being more strongly acted upon, throw out the sensible perspiration also. The coats of all the vessels are perforated by the pores through which the matter of perspiration passes.

As the diseases which arise from obstructed perspiration are sometimes rapid in their progress, Mr. Clark's general remarks on some of the most prevailing, or most dangerous, cannot but be useful in this place.

"Horses generally (he observes) are more exposed to this accident after they have been overheated, more especially when they have been improperly treated, or wholly neglected, as very commonly happens.

When the animal is overheated by active exercises, or by too violent labour, the circulation of his blood is carried on through the vessels with uncommon rapidity. Breathing, consequently, becomes

more laborious to him, and more frequently repeated; whilst, at the same time, the secretion, from the pores of the skin, is considerably increased on the surface of the body, and transpires in humid steam like smoke. It is sometimes so profuse as even to run down, as if water had been poured on the animal's body.

As perspiration is very liable to be suddenly checked by cold, whether applied by a current of cold air, by water thrown upon the body, or by the horse being plunged into it, this secretion is apt to be retained in the body, where it occasions a variety of diseases, which either affect the system in general, as is the case in fevers, or, when more local, affecting the muscles with rheumatism. Hence, in the shoulders, neck, and legs, stiffness and lameness occur. When it affects the internal parts, it occasions colic or diarrhœa. If it settle on the lungs, it produces cough, catarrh, peripneumony, &c. When the pleura is attacked, the most violent pains or stitches, with difficulty of breathing, take place. When the glands of the throat, there is swelling and inflammation, threatening the animal with suffocation, and sometimes suppuration of these glands. When it falls on the windpipe, or the pituitary membrane which lines the cavities of the nose, disorders peculiar to these parts take place, such as the glanders." On the latter, which deserves the particular attention of every veterinarian, Mr. Clark makes many judicious remarks, and has with great accuracy, as we think, considered the enlargement of the contiguous glands (though a circumstance which gives name to the disease) a mere secondary symptom.

"In all the dissections I have made on glandered horses (says he), I never found these [the sublingual] glands affected; but the submaxillary glands that are situated between the jaw-bones on the outside, are always more or less swelled, inflamed, or indurated, according to the length of time they have been affected, or the virulence of the disease; they likewise discharge their lymph into the mouth, as in the human body; and their being constantly swelled in glandered horses, according as one or both sides of the pituitary membrane is affected, may arise from the same cause which produces the swelling of the inguinal glands, in the groin of the human body, in a gonorrhœa; that is, from the absorption of the virulent matter affecting them, and occasioning

PHEASANTS BASKING.

that swelling, induration, &c. Hence it is evident, that the swelling of the sub-maxillary glands in glandered horses, and of the inguinal glands in the groin of the human body, in a gonorrhœa, are only symptoms of these disorders."

Mr. Clark is of opinion, that this disorder may proceed from cold affecting the pituitary membrane which lines the cavities of the nose, &c. "for it generally may be traced to its very beginning, from some cold affecting the head, and which has either been ill treated, or totally neglected. Hence, therefore, it will be evident, that this disorder, like many others to which horses are liable, may be much easier prevented than cured, when once it has taken place." The necessity, he contends, is obvious, for paying proper attention to recent colds in horses; and for restoring the suppressed perspiration by keeping the head and throat warm, and not suffering the horse to go abroad before he is thoroughly recovered.

"When the pituitary membrane is affected with a recent cold (continues he) the small glands which are dispersed throughout its surface become inflamed, and instead of secreting a thin lymph like pure water, which serves to lubricate and moisten the passage of the nose and cavities of the head, as is the case in health, they discharge a viscid mucus, which falls from the nostrils."

When this formidable disease is the result, or even a remote consequence, of obstructed perspiration, no one will deny the importance of Mr. Clark's injunction to preserve horses, by every prudent means, as well from the action of external cold, too frequently arising from currents of cold air or cold water applied to the surface of the body, as from the effects of too much cold water taken into the stomach at once. The same judicious writer, in his observations on suppressed perspiration occasioned by cold air being inspired into the lungs of horses, when they are much heated and agitated from violent

exercise, says, "However dry and elastic the air may be that is drawn into the lungs of an animal body in respiration or breathing, yet, when it is discharged from them, it is evidently loaded with humid steams; and at the same time it loses considerably of its elastic quality. The moisture that comes from the lungs evidently shows, that a very great portion of thin lymph, or perspirable matter, is discharged from them at every respiration; and, as this action is increased and quickened by exercise, the discharge of this fluid will be the greater. But, as very cold air is apt to constrict or shut up, the cuticular pores on the surface of the body, in like manner, when it is applied to the surface of the lungs, especially when they are overheated, it produces the same effect there; hence, that perspirable matter which should be thrown out from them is retained in the lungs, and produces colds, catarrhs, inflammation, and consumption."

The diseases produced by suppressed perspiration probably depend on these circumstances: 1. The degree of cold applied. 2. The longer or shorter period of its continuance. 3. The greater or less susceptibility of the body exposed to it. 4. The predisposition to disease at the time. 5. Its partial or general application. 6. Its operation on distant parts by the medium of the nerves, or what is called nervous sympathy. The means of restoring this secretion are chiefly the application of warm clothing, and the internal use of sudorifics.

PESATE, PESADE, or POSADE, in the manege, is the motion of a horse that, in lifting or raising his fore-quarters, keeps his hind-legs upon the ground, without stirring; so that he marks no time with his haunches, till his fore-legs reach the ground. This motion is the true means to fix his head and his haunches, to make him bend his fore-thighs, and to hinder him from stamping and clattering with his feet.

**PHEASANT.** This beautiful bird is very common in almost all the southern parts of the old continent; but in America it is not known. These birds were brought to Europe by the Argonauts 1250 years before the Christian era; and the bird which the sportsman now finds so numerous and so wild, was originally brought from the banks of the *Phasis* (whence the name *Pheasant*) a river of Colchis, in Asia Minor, and propagated artificially among us, and in other parts of the globe.

The pheasant is second to the peacock only in beauty. It is far

## P H E A S A N T

beyond the powers of the pencil to draw any thing so glossy, so bright, or points so finely blended into each other. We are told that when Cræsus, King of Lydia, was seated on his throne, adorned with royal magnificence, and all the barbarous pomp of eastern splendour, he asked Solon if he had ever seen any thing so fine? The Greek philosopher, no way moved by the objects before him, or taking a pride in his native simplicity, replied, that, after having seen the beautiful plumage of the pheasant, he could be astonished at no other finery.

There have been instances of the cock pheasant weighing three pounds and a half; but the general weight of the male bird may be estimated at from two pounds eight ounces to three pounds: the hen is half a pound less. The length from two feet two inches to three feet. The bill is of a whitish horn colour (the older the bird the whiter will the bill be found); irides yellow, sides of the head deep scarlet, granulated and running into a point behind, and in old birds elongated over each jaw like the wattles of a cock, and dotted with minute black spots: from the nostrils springs a line of greenish black feathers passing under, and a little beyond, the eye; the rest of the neck and head is tinted with gold, changing to violet and blue in some aspects; and in the breeding season there is above the ears, a tuft of these gold tinted feathers that are like horns; lower part of the neck, breast and sides, glossy reddish chequer, each feather margined at the end with black, or apparently purple, according to the light they are viewed in, and under the purple there is a transverse streak of gold colour; each feather on the shoulder and wing covert has more or less of a curved mark in the middle, bounded with a black line both within and without; the lower part of the back the same but less distinct; rump plain reddish brown, glossed with green; belly and vent dusky; the tail, from the middle feather to the end, is about twenty inches, the shortest less than five; and the whole consists of eighteen feathers, regularly shortening towards the sides; all of them have transverse bars of black on each side of the shaft, about twenty four on the two middle feathers, the rest in proportion; the legs are dusky, furnished with a strong membrane between the toes; they have spurs near an inch above the hind toe, shorter than those of a cock, but which increase with their age, and which become in the old birds extremely sharp, though they are round and blunt in the young ones.

The general colour of the female is brown, variegated with grey, rufous, and blackish; the tail much shorter, barred like the male, but of a lighter colour; the regions of the eye are covered with feathers.

We are told the pheasant will live for sixteen years.

This bird, though so beautiful to the eye, is not less delicate when served up to the table. Its flesh is considered as the greatest dainty; and when the old physicians spoke of the wholesomeness of any viands, they made their comparison with the flesh of the pheasant. However, notwithstanding all these perfections to tempt the curiosity of the palate, the pheasant has multiplied in its wild state; and, as if disdaining the protection of man, has left him to take shelter in the

## P H E A S A N T

thickest woods and the remotest forests. Most others of the domestic kind, the cock, the turkey, or the pintada, when once reclaimed, have still continued in their domestic state, and persevered in the habits and appetites of willing slavery. But the pheasant, though taken from its native warm retreats, where the woods supply variety of food, and the warm sun suits its tender constitution, has still continued its attachment to native freedom; and, now wild among us, makes the most envied ornament of our parks and forests, where it feeds upon acorns and berries, and the scanty produce of our chilling climate.

It would appear that the monks of France were well acquainted with the delicate richness of the flesh of the pheasant, since they wished to monopolize it: one of their celebrated preachers, about the year 1216, represented, in one of his sermons, the pheasants, partridges, and ortolans, as addressing themselves to the clergy, and entreating to be eaten by them and them only—"That incorporated with their glorious bodies, they might be raised to heaven; and not go with impious devourers to the infernal regions."

At a later period the pheasant, in some measure, appears to have been held sacred; since, in the year 1453, Philip, Duke of Burgundy, at a great feast (at which were present all his nobility) swore a most solemn oath over a "*roasted pheasant*," that he would march against the Turk who had just destroyed the Grecian empire! His Barons all entered into the same tremendous engagement; but not one of them ever stirred towards the performance of his vow.

The cock pheasants begin to crow the first week in March, and the noise can be heard at a considerable distance: this crowing is an odd sort of noise; and though it is easy to perceive that it is intended for crowing, yet it is very unlike the vigorous salutation of this sort so often performed by the domestic cock:—it is neither so loud, so clear, nor so well defined.

It is asserted that "the male pheasants will frequently come into the farm yards in the vicinity of covers where they abound, and produce a cross breed with the *common hens*; and, it is said, that such is the spirit of the pheasant that this cross is sometimes resorted to by our most experienced breeders of game fowls." Now, all this may look well enough upon paper till it comes to be examined, when it will be found to want that highly essential quality, *truth*. Male pheasants *will not* approach common hens, and "produce a cross breed." If it be possible to induce them to couple with the domestic hen, it must be accomplished, in the first place, by breeding them under the latter, and training them up in a mew or aviary solely in the company of domestic hens; and even then the matter is doubtful. As to the game cock being increased in spirit by a cross of the pheasant, that is still more ridiculous; as the pheasant is by no means a courageous bird—every cross from the pheasant to the game cock could not fail to deteriorate the courage of the latter.

They breed on the ground, but do not pair like the partridge, one cock, like the common poultry, being sufficient for several hens. That pheasants will pair, however, the writer has had many opportunities

## P H E A S A N T

of observing. In the neighbourhood of strong pheasant preserves, nothing is more common than for a young male and female pheasant to stray to some distance to breed: the cock, on such occasions, will remain in the immediate vicinity during the period of incubation, and is generally to be found with the hen and young ones, if unmolested, the whole of the following winter.—The hen lays from twelve to fifteen eggs, which are smaller than those of the domestic hen, and of a deeper colour. The young brood feed and are brought up much in the same manner as the young of the partridge, already described.

When in captivity, the hen pheasant will not lay so numerously as when in a state of freedom; nor will she sit so well, or pay the same attention to her young; in fact, she will frequently not sit at all in confinement; and, in this case, a domestic hen becomes her substitute. The pheasant therefore, on every account, is better left at large in the woods; its fecundity is sufficient to stock the forest; its beautiful plumage adorns it; and its flesh retains a higher flavour from its unlimited freedom.

Both pheasants and partridges are partial to nestling in clover, or other forward grass; which, when mown, too often exhibits occasion to lament this partiality from the number of eggs destroyed by the scythe. Gamekeepers should hunt them from such places, when they are about to lay, until the haunt is broken, when they retire into the corn, or other places. In some places, domestic hens are kept ready to sit upon any eggs\* that may be exposed to the scythe, and with a little attention numbers are thus rescued from destruction. Joseph Warner, gamekeeper to the Earl of Sephton, for the manor of Altcar, in Lancashire, every year hatches and brings up great numbers of partridges and pheasants in this way: the young birds are suffered to escape as soon as they think proper, and they seldom fail to avail themselves of this permission as soon as they can make good use of their wings.

The pheasant hatches about the same time as the partridge, and the young brood remain in the stubbles and hedge-rows for some time after the corn has been cut, if undisturbed; otherwise they seek the woods and strong covers, and only issue thence to feed in the stubbles at morn and eve.

Pheasants, like partridges, devour vast quantities of insects; they feed also on corn; and, when this fails, acorns and the wild berries of the woods are made a substitute for it. We are even told by a French writer, that one of the king's sportsmen shooting at a parcel of crows that were gathered round a dead carcase, to his great surprise, upon coming up, found that he had killed as many pheasants as crows. But, in all probability, the pheasants (supposing the account to be true) had approached the carcase for the sake of the maggots which it contained, and not for the purpose of feeding upon the carrion.

---

\* According to Reaumur, eggs may be preserved fresh and generally fit for incubation, five or six months after they have been laid, by covering the shell with a slight coat of varnish or mutton suet.

## P H E A S A N T

Pheasants continue to sleep on the ground till the approach of winter, they then fly up to roost in the trees ; and when they thus retire for the night, the male, on flying into his roosting place, makes a noise, which is termed *cocketting*, and which he several times repeats ; the hens, on flying up, utter one shrill cry, and are then silent.

In attempting to raise a stock of pheasants, one or two covers that lie convenient for being attended to should be appropriated solely to their accommodation ; wherein should be placed small troughs about four feet long, and the food placed in them should be white pease, of which they are so immoderately fond, that if two neighbouring woods are tried, one feeding with the above, and the second with any other sort of grain, all the pheasants will resort to the pease, and desert the latter. Many persons have little heaps of buck wheat stacked in the woods ; and, where no pease are used, this method may answer very well.

In the early part of October, young pheasants stray from the preserves where they have been bred, and continue at a distance for about a fortnight. In the immediate neighbourhood of strong pheasant preserves, the young birds, which have attained a good size at the period just mentioned, leave the places of their nativity, and ramble to the adjoining fields and covers to the distance of a mile. In these situations they will be found for about a fortnight, and will afford good diversion to the sportsman. But, if unmolested, they will return to their former haunts, from which they were driven perhaps by the hen pheasants in the same manner as we see the domestic hen drive off her chickens when she thinks they are no longer in need of her assistance.

Pheasants shew a decided preference to alder-cars, willow-garths, saltings, or marshes close to the sea, or cliffs with any furze or cover in them, and which join the salt water ; for, like pigeons, they are very fond of salt. If, in such natural advantages of situation, they are moreover tempted to continue by a regular supply, during winter, of their favourite food, they will soon be as plentiful as can be desired : where indeed the pheasant can obtain food, and remain unmolested, he will seldom ramble.

In winter, pheasants, when fed, will come to the keeper's whistle, and will become almost as familiar with him as domestic poultry ; yet they are shy birds, and difficult to be tamed.

The counties of Suffolk and Norfolk are probably more productive of pheasants than any other parts of the kingdom. Upon some of the manors, the numbers have been so considerable, as to admit the killing of two thousand brace of cock pheasants annually. But the extensive slaughter of the cock pheasant is very often productive of the most injurious consequences the following breeding season, and great numbers of addle eggs arise from it. In order to promote as much as possible the breeding of pheasants, all the very old hens should, if possible, be destroyed ; as they become, in a great degree, barren, and create much confusion by driving all the younger and more prolific females from their vicinity.

## P H E A S A N T

When pheasants are kept in a mew, we are told, that the young ones, when first hatched, “should be fed with hard boiled eggs, crumbs of bread, and lettuce leaves, well mixed together, with an addition of the eggs of meadow ants. At this tender age, two precautions are essential, viz. never to allow them any drink, nor carry them abroad until the dew is entirely off (every kind of humidity being hurtful); and that their food be given frequently and in small quantities, beginning at day break; always mixing it with ants’ eggs; the place must be kept extremely clean, and they should be taken in before sun-set. In the second month, nutriment more substantial must be given, such as eggs of the wood ant, wheat, barley, ground beans, wood-lice, ear-wigs, and other small insects, to make a variety; and the intervals between the meals may be gradually prolonged. At this time they begin to be subject to vermin: place small heaps of dry earth or fine sand; by tumbling in which they will soon rid themselves of the painful itching occasioned by them. Water must also now be given frequently, and always clear, else the pip may be contracted; which, as in common chickens, is difficult to be removed: let the bill be rubbed with bruised garlic, mixed with tar. The third month is attended with new diseases; the tail feathers then drop and others appear; a sort of critical period to the pheasant; ants’ eggs, given moderately, are efficacious in hastening the trying moment, and lessening its danger. The young birds may now be carried with the crib into the field where the colony is to be dispersed: if white clover grows in it, the young pheasants will pick the seeds out of the heads, and it will wonderfully strengthen them (white clover seed, given when wheat or other grain is used, will prove very nourishing); they must also at first be fed in the field with some favourite food, but never twice in the same spot, and the quantity diminished daily; and thus, by degrees, they will be constrained to provide for themselves, and become acquainted with the country. When able to procure subsistence, they will soon grow as wild as those bred in the woods; with this exception, that they will retain a sort of affection for those spots from which they were first resigned into liberty and nature.”

We have a more circumstantial process yet to record on this interesting subject, which we shall follow with our own remarks: “it is well worth the observation (says the account, and we find it amongst that turgid mass of incongruities yclept *Daniel’s Rural Sports*) of those who accidentally hatch them from eggs mown over in clover, grass, &c. as when obtained from the eggs of pheasants kept for the purpose.

“Have frames seven feet long, and two feet and a half wide, similar in their form to those for cucumbers, and without a bottom; the large end is to be made as a coop for the hen, the bars wide enough for the young pheasants to run from the hen, to feed in the frame, which is to be covered with a fine meshed net. If pheasants are kept from which the eggs are to be procured, there should be seven hens to one cock; to forward their laying, give white pease; when they drop their eggs, stick them in bran, with the small end down-

## P H E A S A N T

wards, until there are fifteen, which are a sitting for a hen. Get small square boxes, wide enough for the hen to turn in, with covers to hasp down, and holes to admit the air; make a nest of clean wheat straw; every morning, take the hens off, and put them under small coops, allowing to each a quarter of an hour to feed and empty themselves; then replace them on the nest until the next morning: when they have sat a fortnight, remember to sprinkle the eggs every morning with milk-warm water, just before the hen is put upon the nest, to prevent the eggs being shell-baked; when hatched, let them remain with the hen eight hours to dry; then move them into the coop in the frame, upon gravel, in the eye of the sun; feed them with small ant eggs: after a week, move the frame upon grass in a warm place. There must be a sliding board to pen the young with the hen when moved; each frame must have small pens for water, and that for the hen must be fixed to the coop, out of the young bird's reach. Every morning, give the young pheasants curd made with new milk; small ant eggs during the day: at a month's end, put a small piece of saffron into their water, and every morning for each frame give a good sized toast steeped in chamber-lye, which will keep them free from distemper, and is of the first use in causing easy moulting. Use the young birds to a whistle when fed, which should be four times in the course of the day. When the poults are large, there should be a hole in the small end of the frame to let them out and in, and a sliding board to pen them in at night, when they are always to be covered with mats. Before the hole is opened in the morning, there should be food, such as large ant eggs, buck wheat, and other grain, laid near the frame; every day this is to be moved further from it: by so doing they will soon partly learn to take care of themselves, and at the sound of the whistle will come in from all quarters, like pigeons; when they gradually disregard the whistle, and at last desert it, they are safe, and capable of providing for their own sustenance and safety."

The writer has frequently met with *very knowing* gamekeepers, men remarkably wise in their own conceit, who have certain methods for every thing abstruse in their own profession; they affect an air of mystery, and seem to consider a tedious and troublesome process as a striking proof of their superior genius; or, at all events, so they would wish to have it considered; and they thus frequently impose on the easy credulity of their employers. The extracts which we have just given respecting the breeding and management of young pheasants, savour strongly of the manner of a very ignorant, but a very obstinate, gamekeeper. If we examine the matter, we shall find that young pheasants, in a state of nature, are by no means tender birds; on the contrary, they are very hardy, as is abundantly evident from the manner in which they not only endure, but thrive in, this variable, and frequently severe, climate; and if, when it is the question to breed and rear them in a sort of semi-domestic state, we adhere as nearly as possible to that which the law of nature points out, and which is of course practised in the forest and in the fields, surely the chance of success, and of consequent satisfaction, are much

## P H E A S A N T

greater. We have already expressed our ideas on the subject of rearing the partridge, to which we refer the reader, as it will exactly apply in the present case. Joseph Warner, already noticed a few pages back, on the subject of hatching and rearing the young of both partridges and pheasants, and who annually practises the system to a very considerable extent, treats these interesting young birds much in the same way as domestic chickens, only in addition he takes care to supply them with ants and their eggs till they are able to seek this food for themselves. He conveys the ant hills altogether in a cart to the yard, and there empties them out, and allows the young birds to feed and scratch amongst them as they please.

There are several varieties of the pheasant: of the ring-necked pheasant, the Earl of Berkeley had a considerable quantity at Crawford Bridge. The birds are precisely like the common pheasant, except that they have a white ring round the neck. There are white pheasants, crested pheasants, spotted pheasants, pile pheasants, Argus pheasants, but, of all others, the golden pheasant is considered the most beautiful. In the neighbourhood of Blenheim, gold pheasants are to be met with in a state of nature, as well as in some other parts of the country; the gold pheasant is smaller than the common pheasant, but equally capable of enduring the rigours of this climate. What is called the Bohemian pheasant is the largest and the boldest of the pheasant tribe which has fallen under the observation of the writer; the male much more resembles the game cock than any other variety of the pheasant; as this bird is larger and bolder, so he appears more hardy also, and there is no doubt with a little time and not much trouble, might be produced in abundance in our woods. The male will couple with the domestic hen when kept in a mew or aviary: his eye is larger and bolder than that of the common pheasant; he is more ruddy about the head; his neck is beautifully clothed with feathers of a glossy blue black; his back is covered with white striated with black; his tail of a similar colour, but longer and more elevated than that of the common pheasant: his spurs are longer and sharper; nor, when in a mew, does he hesitate to attack any one who happens to enter. The female is brown, less than the cock; she lays a much larger egg than the common pheasant, which is also of a deeper colour.

As the bird last mentioned is larger than the common pheasant, the gold pheasant is smaller; but its plumage is uncommonly beautiful, and of a prevailing crimson-yellow or gold colour; on the head is a most beautiful glossy yellow crest, the feathers of which appear like silk and fall backwards; cheeks almost bare and flesh-coloured; the feathers of the hind part of the head are orange-coloured, square at the ends and crossed with black lines; these are long and can be erected at will, like those on the neck of the cock; beneath these the feathers are green, very little rounded at the ends, and tipped with black; the back and rump are yellow; the upper tail coverts long, narrow, and crimson, and fall on each side the tail; the wing coverts chesnut and brown mixed; scapulars blue; quills brown, marked

with yellowish spots; the tail is long and cuneiform, the largest feathers twenty-three inches, and the outer ones very short; the colour chesnut and black beautifully variegated; the legs are yellow and furnished with a spur a quarter of an inch in length. The female is smaller, and wants the gaudy colours of the male; her prevailing colour is brown, but she is, nevertheless, a much handsomer bird than the common hen pheasant; the eggs of the golden pheasant are somewhat redder than those of the common pheasant, resembling, in some degree, those of Guinea fowl. The gold pheasant will breed, it seems, with the common pheasant: an instance of it is mentioned by Buffon, where a male of the gold kind paired with the common pheasant, but only one young bird was produced, which was a female. The flavour of this beautiful bird is said to exceed that of any other variety of the pheasant.

We have already remarked that Norfolk and Suffolk produce great numbers of pheasants; there are also many other places where these birds are very abundant: in Lancashire, for instance, on the manors of Mr. Watt, at Speke; on those of Mr. Blackburn, at Hale; on those of Mr. Willis, at Halsned; pheasants are very plentiful indeed; as well as in several other places in the same county; and also in many other parts of England. There have been a few produced in Ireland of late years; they are to be met with in tolerable plenty in some parts of Wales; and in the Lowlands of Scotland they are seen; but in the Highlands of that country, where attempts have been made to introduce them, they are very scarce; the mountains of Scotland are not calculated for the propagation of the pheasant, and whatever pains may be taken for that purpose, they will never be attended with much success.

In the month of January, 1810, an uncommon sized pheasant was shot in the plantations belonging to E. L. Irton, Esq. near Whitehaven: it weighed fifty-six ounces, and measured from the bill to the extremity of the tail, one yard five inches!

**PHENOMENON.** A chesnut horse, foaled in 1780, bred by, and the property of, Sir J. L. Kaye, Bart. of Grange Park, near Wakefield, Yorkshire.

Phenomenon was got by King Herod, his dam, Frenzy, by Eclipse, grand-dam by Engineer, great-grand-dam by Blank, great-great-grand dam, Lass of the Mill, by Traveller.

At York August meeting, 1783, Phenomenon won a sweepstakes of 50gs. each, for three years old, colts, 8st. 3lb. fillies, 8st. two miles (seven subscribers), beating Mr. Stapleton's Parlington, Sir W. Vavasour's ch. filly, by Morwick-Ball; Sir C. Turner's brown filly, by Ranthos; and Mr. Harper's Wonderful:—5 to 4 against Phenomenon, and 2 to 1 against Parlington. At Doncaster, Sept. 23, he won the St. Leger stakes of 25gs. each for three years old; two miles, (ten

subscribers) beating Mr. Garforth's Pacolet, Mr. Wentworth's Myrtle, and Mr. Stapleton's Parlington:—5 to 4 on Phenomenon.

At Newcastle-upon-Tyne, Monday, June 21, 1784, Phenomenon won a sweepstakes of 20gs. each, for four years old, colts, 8st. 7lb. fillies, 8st. 4lb. four miles, beating Mr. Bewick's bay colt, by Esper-sykes; Mr. Radcliffe's chesnut colt, by Herod; Mr. Ord's Balloon, and Mr. Burdon's Smart:—Mr. Radcliffe's colt the favourite. On Thursday, he walked over for the Corporation purse of 50l. two-mile heats. At York, August 25, he won one of the great subscription-purses, for five year olds, 8st. 7lb. four miles, beating Mr. Garforth's Faith, and Mr. Wentworth's Latona:—5 and 6 to 4 on Phenomenon. On the 27th, he walked over for another of the great subscription-

purses, for four year olds. Next day he walked over for the Ladies' purse of 50l. At Richmond, Sep. 8, at 7st. 7lb. he won the gold cup, for all ages, four miles, beating Sir W. Wynn's Miracle, aged, 9st.—4 and 5 to 1 on Phenomenon. Next day, he walked over for 50l. two-mile heats. At Doncaster, Sept. 29, he won the gold cup, for all ages, four year olds, 7st. 7lb. four miles, beating Col. O'Kelly's Dungannon, 4 years old, and Mr. Crowle's Moss Rose, 4 years old:—6 and 7 to 4 on Dungannon. Next day, at 8st. 11lb. he won 100l. purse, two mile heats, beating Mr. Crowle's Moss Rose, 4 years old, 8st. 5lb.—20 to 1 on Phenomenon. Same day, at 7st. 7lb. he won the Doncaster stakes of 10gs. each, with 10gs. added, twice round the course, (ten subscribers) beating Mr. Wentworth's Leveret, 3 years old, a feather:—6 to 1 on Phenomenon. Those were the only times of his starting that year.

At York, May 10, 1785, Phenomenon, 8st. 10lb. won a sweepstakes of 10gs. each, two miles, (six subscribers) beating Mr. Garforth's Prince William aged, 9st. 10 to 1 on Phenomenon. This was the last time of his starting. He started only twice besides the above, viz. at Epsom, and was beat by Saltram, &c. for the Derby stakes; and at York, by Maid of the Oaks, beating Myrtle, Cypher, Queen Esther, and another, for a sweepstakes of 25gs. each.

Phenomenon was afterwards a stallion, and covered in 1786, 1787, 1788, 1789, 1790, 1791, and 1792, in the neighbourhood of Boroughbridge, at 10gs. and a half; at Grange Park, in 1793, at 10gs. and a half; 1794, and 1795, at 25gs.; 1796, at 15gs.; 1797, at 10gs. and a half; 1798, at Boroughbridge, at 5gs. and a half.

**PHINOCS.** In the waters in the district of Lochaber, phinocs, a species of trout, are caught in great numbers, fifteen hundred having been taken at a single draught. They come in August, and disappear in November; are about a foot long; their colour grey, spotted with black; their flesh red; they rise very eagerly to a fly, and contribute much to the angler's amusement. The fishermen believe them to be the young of what they call sea trout, weighing thirty pounds: Mr. Pennant supposes this to be the grey trout, and that the phinocs of Scotland are the same species as migrate out of the sea into the river Esk, in Cumberland, from July to September, and are called

whitling, or white trout, although their flesh when dressed is red. They are most delicious eating.

**PHLEBOTOMY.** Until the circulation of the blood was demonstrated, the principles for this practice did not seem so clear as they are at present; and even now there is some diversity of opinion respecting bleeding in particular cases. The taking away blood is only proper when there is too much crassamentum in the vessels, or when it is to avoid a worse inconvenience than that of lessening the already too little quantity of blood. In general, the pulse is the best guide, both as to when to bleed, and the quantity to be taken away. When the pulse is full, strong, or tense, bleeding will always be proper, provided that a plethora be the cause, and not rarefaction; indeed, in old animals, the pulse seems hard from the rigidity of the arteries. In apoplexies from a sanguine plethora, bleeding is the principal means of relief. When bleeding is and is not convenient would require a particular treatise to relate. However, it may here be necessary to make one observation, that though bleeding is one of the most valuable medical remedies, in judicious hands, it often is converted to the most dangerous purposes, when ignorantly or rashly practised. Therefore great circumspection, in many respects, is necessary in the use of this remedy. Where the habit is strong, the pulse full, hard, and quick, it is generally right to take away blood in any disease with which the constitution may be oppressed. Where the habit is weak, and the contrary extremes take place with regard to the pulse, it is almost always wrong. And with respect to the quantity of blood to be taken away, as well as the mode by which the operation is to be performed, in order to relieve some oppressive symptoms which affect the head, lungs, or other of the interior parts, we must be regulated by the nature of the animal's constitution, and consider to which of these circumstances it has the greatest tendency. We shall here particularize the parts of a horse's body proper to bleed in:

1. It is usual to bleed horses in the jugular veins, which lie on each side of the neck, for the farcy, mange, repletion, and several other distempers; and also for repletion, twice a-year, to all horses that feed well and labour but little.

2. Blood is usually taken from the temples, with a small lancet, for bites or blows on the eyes.

3. Farriers have a lancet made on purpose for opening of veins beneath the tongue, for head-aches, or when a horse has been overheated by excessive labour, or for colics, and the vives.

4. It is usual to bleed horses in the membrane of the nose, without any regard whether they hit the vein or not; and this is also done for colics, vives, and being overheated.

5. Horses are let blood in the middle of the palate, above the fourth bar, with a lancet or sharp horn, when they have been harassed, or overheated and seem dull.

6. Blood is taken from the basilic, or thigh veins, of horses, for strains in the shoulders, or the mange in those parts.

7. Horses are blooded in the pasterns, with a fleam or lancet, for strains or infirmities in the hams or knees.

8. They are let blood in the toes, with a butteris or drawing-iron, for bruises in the feet, and infirmities in the legs, such as swellings and affections of the nerves.

9. The flank veins are sometimes opened, with a small lancet made for the purpose, for the farcy.

10. Blood is drawn with fleams in the flat of the thighs, for blows and strains in the haunches.

11. They bleed in the tail or dock, with a long lancet, for a fever and shortness of breath.

**PHYSICING.** The practice of administering purging medicines to horses, is on a supposition that they tend to preserve health, and contribute to activity.

“An indiscriminate use of purgatives (Mr. Denny very properly observes) is so prejudicial in veterinary practice, that more valuable horses have been lost by improper courses of them than from any accidental cause.

It is surprising that this erroneous notion, that horses frequently require to be purged should prevail, and that this important undertaking should so generally be left to the direction of a groom. Reasoning from analogy, would a man, whose strength was daily declining from some defect in the digestive organs, submit to the experiment of taking two or three doses of drastic purgatives, to recover the tone of his stomach, and repair his strength? Certainly not! For every man must know so well the debilitating effect of purging, as to be certain that such a course would tend only to diminish still more his remaining strength.

This evinces the absurdity of that com-

mon practice of giving horses physic in every disease. Discrimination and judgment can alone determine when purgatives are requisite, and when, on the contrary, they are injurious.”

“It is commonly known (says Denny) that besides aloes and calomel, employed as purgatives, there are many others, as jalap, rhubarb, salts, and syrups of various kinds, in daily use, from the supposition that the efficacy of the medicine must be increased by the number of ingredients.

Such is the prepossession in favour of these useless medicines, that I have known men of abilities discountenance a simple but efficacious dose of physic, only because it was not prepared with syrup of buckthorn; which, though obtained genuine, as is hardly to be expected from any druggist, yet it can, in reality, only answer the purpose of so much treacle. The safest and only certain purgative is aloes. In particular cases, calomel is also necessary. But very large doses of other medicines employed for the human subject have no effect upon the horse, as experience sufficiently confirms. This may easily be conceived by those who are acquainted with the structure of the horse's stomach, which differs essentially from that of the human, exclusive of the difference in length of the intestinal canal. Unless therefore the stimulating quality of the medicine remain long after it has passed from the stomach, it will have no effect on the bowels; a circumstance which accounts for the failure above mentioned. The horse, in a state of health, requires a constant supply of food, to repair the waste of the body. As this aliment occupies a large space, the natural motion of the intestines is slow, so as not to expel their contents before the nutritious part is completely absorbed. Again, the quantity of matter remaining in the small intestines requires the constant stimulus of the bile, to propel it into the large ones. A constant supply of bile being therefore required, the horse does not stand in need of a reservoir for that fluid, and therefore is not provided with a gall-bladder; the bile, as it is secreted by the liver, flowing from its duct into the intestines.

Considering, therefore, the length of the intestines, and the slowness of their motion in the horse, it is natural to suppose that a powerful dose of physic will so increase this action, and forcibly propel their contents, as to produce in some part of the intestines violent pain and spasms,

succeeded by inflammation, which frequently terminates in the death of the animal; too many instances of which preclude the possibility of its being doubted.

In all cases, therefore, where the strength of the animal is not exactly ascertained, a small dose should be first given, which may be afterwards increased, if found necessary: thus every advantage will be secured, without hazard; for horses of the same breed, and size, differing as much in constitution as the human subject, the same dose, at different times, will produce very different effects."

Mr. Denny, in a very adequate manner, points out the cases in which purging physic may be used with advantage.

"Horses coming from camp (says he) into warm stables, should have one or two doses of mild physic administered.

Many of those inconveniences that arise from a sudden change of temperature, as swelled legs, inflamed eyes, colds, &c. would also be prevented, by having the doors and windows kept open, to admit a free passage of air during the few first days. It is likewise advantageous to give each horse a cold mash or two daily, and afterwards close the doors and windows gradually, to prevent any bad consequences from the transition, which might otherwise be hurtful.

Young horses should always have two or three doses of physic; and afterwards sufficient time allowed them to get into condition before they are sent to the riding-school. The service loses annually many valuable horses, by their being too hastily formed for the ranks; which generally produces inflammation of the lungs.

Horses require physic after having been long fed on green food; and also in the autumn, before preparing them for the field. Those also that have swelled and cracked heels, from their high feeding, or irregular exercise, will be much benefited by purging physic."

We cannot omit the following, which Mr. Denny has found extremely useful as physic for horses.

*Purging Balls.*

No. 1.

Take of Barbadoes aloes, in fine powder, four drachms;

Ginger, in fine powder, one drachm;

Treacle, enough to form the ball.

This is particularly suited to blood horses.

No. 2.

Take of Aloes, in fine powder, six drachms;

Ginger, in fine powder, one drachm and a half;

Treacle enough to form the ball.

This is better adapted for horses used in hunting, or on the road.

No. 3.

Take of Aloes, in fine powder, one oz.

Ginger, in fine powder, two drachms;

Treacle, enough to form the ball.

This is suitable for labouring horses.

The author observes, that if these doses should not be found sufficiently strong, a drachm or two of aloes may be added to any of them. In those cases where mercurial physic is deemed necessary, it is a commendable practice to give a calomel ball in the evening, and the aloëtic purge, No. 1, the next morning.

The following are Mr. Denny's

*Mercurial Balls.*

No. 1.

Take of Calomel, one drachm;

Aniseeds, in powder, half an ounce;

Treacle, enough to form the ball.

No. 2.

Take of Calomel, one drachm and a half;

Aniseeds, in powder, half an ounce;

Treacle, enough to form the ball.

No. 3.

Take of Calomel, two drachms;

Aniseeds, in powder, half an ounce;

Treacle, enough to form the ball.

He advises the second aloëtic ball to follow the mercurial ball, No. 3, as these will be found sufficient.

The treatment of horses during a course of physic should be as follows:

"Mashes of scalded bran, with a handful of corn in each, should be given for one or two days previous to taking the ball, which is to be given early in the morning.

Two or three quarts of warm water only to be allowed for the first four hours. Afterwards give a warm mash, which is to be repeated two or three times during the day. The water given should be warm, but not in larger quantities than

usual. A small allowance of hay is proper at night. If mashes and water be refused, as is often the case, gruel must be given instead of them.

Next morning the horse should be walked out, for half an hour, or longer, if necessary; at which time the physic generally operates. He may be exercised again in the middle of the day.

Mashes and warm water are to be continued until the evening. His feed may then consist of equal parts of dry bran and oats; and the following day his food be as usual.

Horses under physic require additional covering; they being then more susceptible of cold than at any other time.

The practice of trotting horses violently, to assist the operation, is both absurd and dangerous. Almost every instance of physic failing to produce its effect is in consequence of mismanagement or neglect in the stable.

An interval of eight or nine days must be allowed before the second dose is given, during which period he should have one or two hours' walking exercise daily, taking care that he be well groomed on his return to the stable, and regularly fed."

*Purging Horses.*—Purging medicines are given to horses with different intentions, that is, either to prepare their bodies for active exercises, or to cure them of diseases. In the first case, they are always to be considered as in a state of health; in the second, in that of disease. Previous to entering on these different heads, and that they may be better understood, it will be necessary to premise a few things relating to the stomach and intestines, the chyle, the different systems of vessels, with their contents, which will serve to illustrate what may be advanced on the subject of purging horses.

The stomach of a horse, notwithstanding his size of body, is but small, and its coats are thin; the numerous circumlocutions and foldings of the intestines, are wisely ordered, to detain the aliment till such time as it is thoroughly drained of its nourishing particles by those vessels called the lacteals, the office of which is, to absorb or drink up, and to convey the chyle or nourishment into the blood; their mouths open into the inner cavity of the intestines. The length of the alimentary canal, from the upper end of the gullet to the anus or fundament, is said, by Doctor Braken, to be about 35 yards. The intestines have a motion peculiar to them-

selves, which forms its resemblance to that of a worm, is called *peristaltic* or *vermicular*; according as the motion is diminished, the evacuation by stool or dunging is in a great measure regulated.

The stomach is supplied with a humour or juice peculiar to itself, which, by mixing with the food, as the saliva, bile, and other juices, supplied by the pancreas, &c. undergoes a fermentative process of a peculiar nature, which is called digestion, and from which the chyle is the result.

The insides of the intestines are covered with a slimy mucus, which is separated from the glands, in order to preserve them from being irritated by the food, in its passage backwards. The coats of the stomach and intestines are supplied with an infinite number of blood-vessels and nerves, which are every where dispersed; and hence they are exceedingly liable to inflammation, irritation, spasms, &c.

Besides the vascular system, which includes the arteries and veins, there may be said to be another system of vessels, called *absorbents*; they are of two kinds, the lacteals, and the lymphatics. The use of the former has been already mentioned. The lymphatics are tubes or canals, furnished with valves, which convey fluids that are taken up by absorption on the external surface, and from the extremities of the body; they likewise absorb particular fluids from the different cavities of the body, and from the cellular parts, &c. which are by them conveyed into the thoracic duct, where it is mixed with the chyle, and from thence it is carried into the blood.—Let us now consider the manner in which purging medicines operate on the first passages only.

The action of purging medicines consists in irritating the sensible fibres of the stomach and intestines, by which means, not only the peristaltic motion of the latter is very considerably quickened, but also the secretions of mucus and lymphatic juices, and vapour, which ooze every where into the cavities of the intestines, are increased, together with unusual quantities of pancreatic juice and bile from their several sources; hence it will be obvious, how great a quantity of the soundest humours, or even the chyle that is derived from the food, before it is mixed with the blood, may be carried off by purging medicines, and how much the whole mass of fluids in general may be decreased and drawn off.

Since, therefore, purging is occasioned by giving such medicines as are found, by

their irritating quality, to stimulate the coats of the stomach and guts, and, at the same time, quicken the peristaltic motion of the latter, so as to cause them to shake or throw off their contents by stool, it would appear, that the different kinds of purging medicine differ only in degrees of strength, and that they operate no otherwise upon the different humours of the body than as they stimulate the first passages more or less, and hence cause a greater or lesser evacuation by stool. So that, by this operation, we only lessen the quantity of the fluids, and clear or scour the first passages from any offending matters that may be lodged there. From hence it may likewise be inferred, that there is no such thing as elective purgation, that is, by giving certain medicines, we drain off this or that particular humour from the body. This may be farther illustrated in the following case or example :—When a horse, which has swelled legs, or greasy heels, gets purging medicines, they do not act immediately on the fluids contained in the legs, by carrying them off only, they act by revulsion, that is, by drawing away the fluids, &c. from the stomach and intestines; those that are in the legs are, at the same time, absorbed or drawn away from the extremities by the absorbent vessels, to supply the want in the former; and hence the swellings in the legs, &c. subside.

It is a common phrase, when a horse is any way out of order, to say, that such a horse is foul in the body, or that he is full of humours, an expression which can only mean that the horse is in a bad habit of body; as to a horse's being full of humours, the propriety of the expression in this sense cannot be admitted, as every horse, even in the highest state of health, properly speaking, is full of humours, as every gland in the body, of which there is a considerable number, separates a particular humour, which becomes necessary for a variety of purposes in the animal economy; thus, the liver separates the bile, the testicles the semen, and every joint in the body has its glands, which separate a particular humour, and so of others. Therefore, the expression or phrase of a horse's being full of humours, in the common acceptation of it, is improper, and betrays a want of knowledge of the animal economy.

Many people are but too fond of giving purging medicines, and frequently prescribe them whether the case may re-

quire them or not, Doctor Bracken has a very pertinent remark on this head.—“This sort of evacuation (says he) seems very much to quadrate with the outward senses, and makes the ignorant part of mankind (whose heads are fuller of humours than their horses) imagine, that purging medicines carry off the offending matter in most disorders, never considering the general rule, which ought still to be kept in mind, viz. that, in proportion to any one evacuation's being heightened or increased, most, or all, of the other natural evacuations, are proportionally diminished.”

It is a practice with many people, to ride their horses very hard before they give them purging medicines, in order, as the phrase is, to stir up the humours, that, when they are afloat, (according to their ideas) they may be carried off by the purging. It has been already observed how exercise operates on the blood, by increasing its velocity to a great degree, and hence inclining it to an inflammatory disposition, which, in this case, is the very worst thing that could happen, upon the supposition that the horse is in a bad habit of body; for purging medicines, when they are given in this state, may occasion inflammation in some of the principal viscera or intestines; or they may bring on a fever, or other disorders, which, if they do not prove mortal, yet they may, as is sometimes found to be the case, occasion those disorders that terminate in blindness, incurable lameness, or in some chronic disorder, which may render the horse useless.

Riding horses about the day after they have got purging medicines, in order to forward their operating, if continued too long, till the horse is warm, or to produce sweating, ought always to be guarded against, as such treatment not only exposes them to catch cold, but hinders the operation of the medicine in the ordinary way; for it has been observed, that purging medicines sometimes go off by sweat, or by urine, &c. which the ignorant and unskilful are not acquainted with; they therefore conclude, that, as they see no great discharge of dung, the dose has been too weak, and give another too soon, without allowing a proper interval between them, which, at the same time, is made considerably stronger than the former, which weakens the horse very much, and a considerable time elapses before he recovers his usual strength.

I have already taken notice of the

great length of the intestines ; this, together with the horizontal or prone position of the body of a horse, is unfavourable to the operation of purging medicines, which, on that account, remain in the bowels a considerable time before they operate, being from eighteen to twenty-eight or thirty hours, according to the state of the bowels at the time, and, in some constitutions, even longer. In these cases, it is not advisable to give any medicines in order to quicken or hasten their operation ; walking exercise, but not long continued at a time, together with plenty of warm water, if the horse will drink, is the best and the safest means to forward the operation of them. At the same time, it will be necessary to notice whether the horse stales more than usual, as purging medicines, as I have just observed, are found sometimes to operate in that way, without any considerable evacuation by dung. I would likewise recommend a general caution in giving purging balls, which is, that the operator should push the ball over the root of the tongue, and that he be certain of the ball's being swallowed entire, and not broke or thrown out of the mouth ; mistakes of this kind have frequently occurred : when the ball breaks, one half, perhaps, is only swallowed, the other drops out of the mouth, or it may happen that the whole ball drops out unperceived. In these cases, it is concluded, from the purge's not operating in due time, that it has been too weak, and, therefore, the next dose is made considerably stronger, and hence a superpurgation ensues, attended with great sickness, loss of strength, and other bad consequences ; therefore, when purging balls are given to horses, the head should be kept up, and care taken that the ball passes down the gullet, which may easily be discovered sliding down from the outside ; but, if any doubt remains of its being swallowed, a little water may be given the horse to drink, and one gulp or two will put it out of all doubt.

It is a common practice to give purging balls early in the morning, upon an empty stomach ; this, in some constitutions, occasions great sickness, faintness, trembling, griping pains, &c. a long while before they begin to operate ; to prevent which, I have always ordered, and with success, a mash of bran to be given about an hour before the ball, which prevented these effects, and the purge operated in the most gentle and easy manner ; and,

perhaps, this practice would be advisable in all cases, and in all constitutions, when purging medicines are necessary.

Another error many people fall into is, that, although a purge operates very well, yet, if the horse is not very sick during its operation, they conclude that it will have no effect, nor will be of any benefit to the horse ; they therefore give the next purge made a good deal stronger, in order, as they say, to stir up the humours ; for they conclude, that the sicker a horse is under this operation, the humours are the more stirred up, and the easier carried off by the purge, without considering the danger that attends this operation, and how much they expose the life of the horse by such injudicious treatment.

When purging medicines are intended to be given to horses, it is necessary that they should be kept quiet, and rest for some time before, that is, from any violent exercise ; and the same rule should be observed for some days after they have done operating, walking exercise only excepted. It is owing to the want of these, and such like precautions, already mentioned, that so many accidents happen daily in the purging of horses.

It may be now expected, that I should make some observations upon the practice of purging horses, by way of preparing them for the race course, hunting, &c. It must be acknowledged there is a difficulty in combating a practice which too generally prevails, although there are a number of facts which will serve to demonstrate, that the purging of horses indiscriminately is not necessary in order to prepare them for these active exercises. On the contrary, it must, and indeed is, in many cases, exceedingly hurtful to horses, on account of the too frequent repetition of them, together with the too short intervals generally allowed between each purge.

As to the vulgar opinion of humours falling down into this or that particular part of the body, if horses are not properly purged, &c. before they are put to these active exercises, it is exceedingly erroneous, and must depend on a variety of circumstances, that ought to be taken into the account.

It may be of use to the young practitioner, to explain what is meant by the phrase of humours falling down ; but, at the same time, I must inform him, that this phrase is so generally in use, that, when a horse's eyes are affected, the humours are said to fall down into them,

although they are situated nearly in the most elevated part of the body. But, to explain their falling down to the extremities, I shall take a case that frequently occurs :—When a horse that is in the highest state of health, but too fat and full of juices, &c. and accustomed to stand much at rest, is suddenly put to violent or long continued exercises, his legs, &c. will be apt to swell soon thereafter ; they will perhaps continue in that state for some time ; they may at least break out in running sores about the heels, and form cracks, scabs, &c. ; in this situation, it is then said that the humours have fallen down to the legs. Here a question naturally occurs, where were these humours before the horse got this hard ride, or other severe exercise, and how came they to fall down on this occasion only ? This requires a different explanation.

It has been observed, in the article on exercise, the effects it produces when too sudden and violent, before a horse is gradually habituated to it for some time previous to his undergoing such violent or long continued exercises. The vessels being too full of fluids, they, from the rapidity of the circulation during the exercise, especially the finer capillary vessels, admit the grosser fluids that do not circulate in them in ordinary ; they likewise are liable, in these cases, to rupture ; hence the fluids they contained are extravasated into the cellular parts, where they stagnate, and, being then out of the course of circulation, they occasion a swelling. If this happen in the legs, as they are the most depending parts of the body (the humours are then said to be fallen down), the swelling causes a distension of the skin, &c. ; the cuticular pores are then enlarged, and admit through them the thinner parts of the fluids to the outward surface on the skin, which, on being exposed to the external air, are then changed in their quality, and acquire, according to circumstances, either a soapy, clammy, or greasy appearance, or a sharp, foetid, ichorous quality, that erodes the skin, and, by lodging there, forms small ulcers.

It is well known, that horses, by good feeding, regular exercise, &c. may be brought to perform the most active exercises, and that many instances daily occur of horses both running and hunting, without undergoing any previous preparation by purging medicines ; and it is likewise well known, that, even when purging medicines are given, still regular exercise

is found to be absolutely necessary, in order to habituate the horse to this kind of active labour.

Post horses likewise furnish a farther proof of what has been advanced ; it is well known how they can be brought to travel very long stages, and with great speed, without any preparation farther than good feeding, and inuring them by degrees to this violent labour. Dr. Bracken, who understood this subject very well, and who was likewise a great sportsman, has been at great pains in exploding this manner of reasoning, by a variety of sound arguments, in his second volume of farriery improved, where he has likewise given it as his opinion, “ that in most cases, good feeding, regular exercise, &c. will, in time, make a horse fit to start for a plate, without so much noise of the virtue of this or that drug or composition, to carry off grease, and mend his wind ; for, in my humble opinion, the jockeys are too fond of giving purges to horses, whereby they weaken their constitution, by causing the fibres of the stomach and guts to become lax and flabby.” And, in the same volume, he mentions the following case of a mare of his own, “ that she had run six years with only two purges ; neither had she an ounce of any kind of medicine during that time, except every morning, and mostly every evening, about the bigness of a pigeon’s egg of my cordial ball ; and, I fancy, she performed as well as most of her neighbours, for she won eight plates out of nine, and four out of six every year.”

It ought always to be remembered, that great evacuations weaken an animal body, and if they are repeated too frequently, and too close upon one another, without allowing a proper interval between each, or, if they are carried to excess, which is sometimes the case, the weakness in the animal system is thereby increased, the powers of life are quite overcome, and death follows of course.

I would not be understood, from what has been said, to mean, that purging medicines are never to be used on these occasions—no, I am fully sensible of their good effects, when judiciously administered, and horses properly managed during their operation ; but I do not approve of repeating purge after purge, merely because this or that horse is to run or hunt, without first considering whether the animal be fat or lean, or whether he has been kept at hard meat, with proper exercise, or whether he has run a con-

siderable time, or late in the season, at grass ; all these, and a number of other circumstances necessary to be attended to, ought to be duly weighed, and maturely considered, before purging medicines are administered ; for example, if a horse has run long at grass, and is of a plethoric or full habit of body, evacuations by purging, and diuretic medicines, to a certain degree, are necessary, together with length of time, good feeding, and regular exercise, to bring his body into that proper habit to enable him to perform, with freedom, such active exercises. But, if a horse is of a lean, low, or dry habit of body, whether it may proceed from the want of proper food, from fatigue, &c. why reduce him still lower by repeated evacuations of any kind ? There is such an inconsistency in this practice, that it would not even deserve to be mentioned, or taken notice of, if it were not too much practised every day ; for, with some people, it is no matter of consideration with them what state or habit of body a horse may be in, that is, whether he be of a fat, or full, or lean dry habit of body, still he is said to be full of humours, and which must be purged off before he can run, &c. Horses, in the latter situation, require only good feeding, and regular exercise, to strengthen and improve their constitutions, which cannot fail of taking place, if the viscera are sound, and the horse otherwise in a healthy state. And, even although a horse may be a little inclined to be fat, or of a plethoric habit, yet, from the use of diuretic medicines, which are commonly given on these occasions, together with regular airings and proper exercise, good feeding, dressing, &c. he may be brought into that proper habit of body, which will enable him to perform the most violent labour with the greatest ease to himself, and without any bad consequences arising from it.

But, farther, from the too frequent use of purging medicines to horses, their constitutions, though otherwise good, are ruined by it, their strength is impaired ; it likewise contributes to shorten their days. Besides, it frequently happens, that, when they are brought to action too soon after such evacuations, their strength being quite exhausted by the treatment they have undergone, they fail in performing what was expected from them.

From these, and a variety of other arguments which might be urged, and which will readily occur to the judicious reader, it is obvious, that repeated evacuations,

of any kind, are not necessary to horses, in order to prepare them either for running or hunting ; and, if those that are intended for the latter were only allowed the spring grass, and taken up about the middle or towards the end of June, before the grass becomes too rank, although it may be rather inconvenient to have them in the house at that season, yet the owner would find his account in it ; the allowance of oats may be but small for some time, and which might be increased, together with the horse's exercise, as the hunting season approached. Running horses might be treated in the same manner, according to the season in which they are to run, allowing both a greater length of time in the habitual practice of these exercises, together with proper feeding, dressing, &c. This treatment, together with the use of those alterative and diuretic medicines, which are usually given on these occasions, would render horses much stronger and fitter for these active exercises, without wearing out their constitutions by the repeated use of purging medicines, too frequently very injudiciously administered.

I shall close this head with a case that happened here some years ago : Two military gentlemen betted their horses to run against one another on Leith sands, for a considerable sum, and which was to take place three weeks after the bet ; the horses to be rode by their grooms. Captain R—'s was a pony about thirteen and a half hands ; Captain M—'s was a gelding about fifteen hands high ; both their grooms were bred at Newmarket, and were keen advocates for bleeding and purging (notwithstanding both the horses had been kept on dry food and in the best order, and the short interval of time for such treatment), in order to prepare them for running, &c. Captain M—'s horse was blooded once, and purged twice ; Captain R—'s was blooded once, and purged once ; they were both sweated in the stable with a great load of clothes ; at the same time, their stables, though separate, were kept uncommonly hot and close shut up, night and day, in the midst of summer. From this treatment, they soon lost their appetite for food, and, in about eight or ten days, they were hardly able to undergo their exercise on the sands, their strength was so much exhausted by the treatment they had undergone, the constant and violent sweating in the stable, which, of all evacuations, when continued, weakens a horse the

most. In this situation, Captain R— gave up his bet as lost, together with his pony, for which he had a great value; luckily for him, however, his groom, who was rather inclined to be corpulent, had put himself under a course of physic, &c. in order to reduce his weight; the pony was then put under my care, with another groom to attend him; his cloathing was immediately reduced to a single rug, the stable windows were thrown open in order to admit fresh air, the pony recovered his appetite for food, together with his strength, spirits, and activity; whilst his antagonist continued under the manner of treatment above mentioned. And, although bets were considerably against the pony at starting, yet he won with great ease, and which Captain R— frankly acknowledged was entirely owing to the difference of treatment they had been under.

I have hitherto confined my observations on the administering purging medicines to horses in health, in order to prepare them for active exercises, as running, hunting, &c.; it remains to consider their use in diseases.

It would take up too much of the reader's time to enumerate the various forms of prescriptions that are in use for purging horses, or to confute the ridiculous encomiums bestowed on the variety of recipes that are handed about with a *probatum est*, or attestation of their peculiar virtues in carrying off this or that particular humour, &c. as many of these compositions, when examined, appear to be a confused jumble of ingredients, calculated more for the apothecary's profit, than benefit to the patient; and the bad effects arising from them in practice, are too apparent in a variety of cases which occur daily.

The substances that are used for purging or emptying the alimentary canal, may be distinguished into two kinds, the lenient, which open the belly gently; and the drastic, which purge more briskly. The lenient ought always to be preferred when there appears any unusual commotion in the vascular system, which may easily be known from the quickness of the pulse, &c.; for, although purging medicines increase the motion of the pulse during their operation, yet they afterwards abate or lessen the motion of the blood, by drawing off a considerable quantity of the animal fluids by stool; they likewise clear the intestines of sharp stimulating matters or worms, which occasion an unusual degree of irritation in the system; they

likewise may be given with different intentions, as circumstances may require, in small doses, to keep the body open, and prevent an accumulation of faeces or dung in the intestines, which happens in diseases. In cases of frequent returns of the gripes or cholic, but not during the fit, lest the guts should then be inflamed, they should therefore be given in the intervals, in order to prevent the return of the complaint.

But, in cases where it is thought necessary to clear the intestines thoroughly in strong robust horses, the drastic purges may be given, provided there is no great commotion in the circulation of the blood at the time. Purging medicines are of great service in cases where the intestines appear to be loaded with viscid or thick slime, or when it appears, by long continued costiveness, that the peristaltic motion of the intestines is in some degree suspended; in gross habits, especially where there is any tendency to swelling in the legs, attended with running sores, &c.; in dropsical swellings in any part of the body; in diseases of the head, rheums, or defluxions about the eyes; in rheumatic lameness, when the pains seem to move from one limb to another; in the jaundice; in obstinate coughs, especially when the horse is of a full habit of body; in most cutaneous diseases, or when a number of small pimples or lumps arise on the skin, and suddenly disappear again, or when the lumps discharge a sharp fluid of an ichorous quality; in plethoric or full habits, when the horse is intended for violent or active exercises, as running, hunting, &c. in cases where it is judged necessary to lessen the general mass of fluids, or to divert them from flowing to any particular place in too great a quantity, as in inflammations of the lungs; in this last case, liquid purges are most proper, as they operate more expeditiously. In very delicate constitutions, rhubarb should constitute the greatest part of their purging medicines; they are likewise most proper in cases of want of appetite; no doubt there may be other cases where purging medicines may be necessary; but these must depend on the discretion and judgment of the prescriber.

On the other hand, it will be prudent to avoid giving purging medicines during extreme cold weather; likewise in all feverish complaints, when the pulse beats strong and quick, till such time as these symptoms are considerably abated; in all

cases of extreme weakness, whether arising from fatigue or long continued diseases; in all lean dry habits, unless there is reason to apprehend it proceeds from worms; in cases of very obstinate costiveness, till such time as that complaint is in some degree removed by clysters, soft feeding, &c.; in cases when a horse labours under any violent acute complaint; in diarrhœa or looseness. Aloetic purges, or those in which aloes enters into the composition, are to be avoided likewise in severe colicks or griping pains, although liquid purges, that are quicker in their operation, and less irritating, may be given with safety in the intervals, when it is observed that horses are subject to frequent attacks of this complaint.

Previous to the giving of purging medicines to horses, especially to those which have been kept on hard meat, it will be prudent to keep them from all violent exercises for some days before the purge is given. If they are fat, and of a full habit, it will be necessary to draw some blood, to lower their feeding, and to give them that which is soft and relaxing, as boiled barley, mashes of bran, malt, &c. When horses are to be purged at grass, no preparation is necessary, farther than, in plethoric or full habits, to treat them as above, observing, at the same time, that they be not costive, as this frequently happens although feeding on grass; in that case, they are to be taken into the stable, and treated as if they had been on hard feeding.

In giving purging medicines to horses, it will always be most prudent to begin at first by giving mild lenient purges, in order to find out the strength of the constitution, &c. as very strong robust horses, to appearance, are sometimes easier purged than those of a more delicate make; and it frequently happens, that the same horse is easier purged at one time than at another, according to the state of the stomach and intestines at the time the purge is given.

Mild purges are therefore much safer at all times, and of more benefit to the constitution, than too strong ones; for the latter cause too great an irritation of the stomach and bowels; hence follow

griping pains, great sickness, &c. and sometimes inflammation of the intestines; they likewise may occasion a superpurgation, by which the bowels are so much weakened, that they never afterwards recover their former tone; and hence follow loss of appetite, general weakness, and, perhaps, an habitual diarrhœa or looseness.

When it is intended to give mercury with purging medicines, which is necessary in cases of worms, or as an alternative, it is proper to give the mercury in the evening, and the purging-ball the next morning, as formerly directed. In this case, great care should be taken that the horse be not exposed to cold, nor suffered to drink very cold water, although he may be indulged in plenty of water milk-warm, mixed with a little oatmeal.

**PIAFFEUR.** In the manege, a kind of movement in a proud and stately horse that, being full of mettle, wishes to go forward; this excessive eagerness makes his motion the greater as you endeavour to keep him in, and bends his leg up to his belly: he snorts, traverses if he can, and by his fiery action shews his restlessness, whence some, though very improperly, say, he dances. Such horses as these, or such as are bred to passage upon a straight line, are much admired in processions and magnificent festivals.

**PICKER.** A horse-picker is a small iron instrument, so truly convenient upon many emergencies, that a prudent traveller, or experienced sportsman, is hardly ever seen without one annexed to the handle of a knife which he carries in his pocket: its use is to extract stones, pebbles, or flints, from the bottom of the foot, when they are picked up in hunting, or upon the road. They are sometimes so firmly fixed between the inner edge of the shoe and the frog, that nothing but very violent force with a hammer can remove them; in such cases, horses are sometimes led a considerable distance to some dwelling house, before the stone can be extracted; and the foot is probably bruised, or sustains a serious injury, for what might be obtained at a trifling expense, and carried with little inconvenience.

**PIGEON, THE.** The pigeons constitute a tribe that forms a connecting link between the passerine birds and the poultry.—They are much dispersed over the world, some of the species being found even in the arctic regions. Their principal food is grain; they drink much; and not at intervals like other birds, but by a continued

## P I G E O N

draught, like the quadrupeds. During the breeding time they associate in pairs, and pay court to each other with their bills. The female lays two eggs, and the young that are produced are for the most part a male and a female. They usually breed more than once in the year; and the parent birds divide the labour of incubation by sitting alternately on the eggs.

Both the male and female assist in feeding their young. This, in most of the species with which we are acquainted, is done by means of a substance in appearance not unlike curd, and analogous to milk in quadrupeds, that is secreted in their crop. During incubation, the coats of the crop are gradually enlarged and thickened, like what happens to the udders of female quadrupeds during the time of uterine gestation. On comparing the state of the crop when the bird is not sitting, with its appearance on these occasions, the difference is found to be very remarkable. In the first case, it is thin and membranous; but when the young are about to be hatched, it becomes thicker, and takes a glandular appearance, having its internal surface very irregular.—Whatever may be the consistence of this substance when just secreted, it probably very soon coagulates into a granulated white curd; and in this form it is always found in the crop. If an old pigeon be killed just when the young ones are hatching, the crop will be found as above described, having in its cavity pieces of white curd mixed with the common food of the bird, such as barley, pease, &c.—The young pigeons are fed for a little while with this substance only: about the third day some of the common food is to be found along with it. As the pigeon grows older, the proportion of the common food is increased; so that by the time it is seven, eight, or nine days old, the secretion of the curd ceases in the old one, and of course no more is found in the crop of the young.—It is a curious fact, that the parent pigeon has at first a power to throw up this curd without any mixture of common food; although afterwards both are thrown up in the proportion required for the young ones.\*

Pigeons have a weak, slender bill, straight at the base; with a soft protuberance, in which the nostrils are situated. The legs are short, and in most of the species red; and the toes are divided to the origin.—The voice of these birds is plaintive and mournful.

*The wild-pigeon.*—This bird, from being the parent stock whence all the varieties of the domestic pigeon are derived, is often called the stock-dove. It is still found in many parts of our island in a wild state: forming its nest in holes of rocks, and old towers, and in the hollows of trees; but never, like the ring-dove, on the boughs.

Multitudes of wild-pigeons visit us in the winter, from their more northerly summer retreats; appearing about November, and again retiring (except a few that breed with us) in the spring. While the beech woods were suffered to cover large tracts of ground, these birds used to haunt them in myriads, frequently extending above a mile in length as they went out in a morning to feed.

---

\* What is here termed curd, is not literally such, but is so called from its much resembling that substance in appearance. Hunter on Anim. Econ. p. 235.

## PIGEON

In a state of domestication, these pigeons are rendered of very material service. They frequently breed eight or nine times in a year ; and though only two eggs are laid at a time, their increase is so rapid and prodigious, that, at the expiration of four years, the produce and descendants of a single pair may amount to the immense number of nearly fifteen thousand.

The usual way to entice pigeons to remain at a required spot, is to place what is called a salt-cat near them : this is composed of loam, old rubbish, and salt, and will so effectually, it is said, answer the purpose as to decoy even those belonging to other places ; it is on this account held illegal.

We have a singular anecdote related of the effect of music on a pigeon, by Mr. John Lockman, in some reflections concerning operas, prefixed to his musical drama of *Rosalinda*. This person being at the house of Mr. Lee, a gentleman who lived in Cheshire, and whose daughter was a fine performer on the harpsichord, he observed a pigeon, which, whenever the young lady played the song of “ *Speri si*,” in Handel’s opera of *Admetus* (and this only), would descend from an adjacent dove house, to the room window where she sat, and listen to it apparently with the most pleasing emotions ; and when the song was finished, it always returned immediately to the dove house.

There are upwards of twenty varieties of the domestic pigeon ; and of these the carriers are the most justly celebrated. They obtained their name from the circumstance of their conveying letters and small packets from one place to another.

It is through attachment to their native place, and particularly to the spot where they have brought up their young, that they are thus rendered useful to mankind. The bird is conveyed from its home to the place whence the information is intended to be sent ; the letter is tied under its wing, and it is let loose. From the instant of its liberation, its flight is directed through the clouds, at an amazing height, to its home : by an instinct altogether inconceivable, it darts onward in a straight line to the very spot from whence it was taken ; but how it can direct its flight so exactly, will probably for ever remain unknown to us.

These birds are not now rendered of the same use as formerly, in carrying letters from governors in besieged cities to generals about to relieve them ; from princes to their subjects, with tidings of some fortunate event ; or from lovers to their mistresses with the dictates of their passion ; nor, since the executions at Tyburn have ceased, will they again be let loose the moment the fatal cart is drawn away, to notify to distant friends the departure of the unhappy criminal.

The rapidity of their flight is very wonderful. Lithgow assures us, that one of them would carry a letter from Babylon to Aleppo (which, to a man, is usually a thirty days’ journey) in forty-eight hours.—To measure their speed with some degree of exactness, a gentleman some years ago, on a trifling wager, sent a carrier-pigeon from London by the coach to a friend at St. Edmund’s Bury ; and along with it a note, desiring that the pigeon, two days after its arrival

## P I G E O N

there, might be thrown up precisely when the town clock struck nine in the morning. This was accordingly done; and the pigeon arrived in London, and flew into the Bull-inn, in Bishopsgate-street, at half an hour past eleven o'clock, of the same morning, having flown seventy-two miles in two hours and a half.

The carrier-pigeon is easily distinguished from the other varieties, by a broad circle of naked white skin round the eyes, and by its dark blue or blackish colour.

*The ring-dove.*—These are the largest of all the British pigeons, generally weighing about twenty ounces; and may at once be distinguished by their size from all the rest. They build on the branches of trees, generally preferring those of the pine. The nest is large and open, formed principally of dried sticks; and the eggs, which may be frequently seen through the bottom of the nest, are larger than those of the domestic pigeon.

The food of this, as well as of the other species, is principally grain: but a neighbour of the Rev. Mr. White, of Selborne, shot a ring-dove as it was returning from feeding, and going to roost; and when his wife had picked and drawn it, she found its craw stuffed with the most nice and tender tops of turnips.

Hence we may see that granivorous birds, when their usual kinds of subsistence fail, can feed on the leaves of vegetables. There is indeed reason to suppose, that they would not be long healthy without these substances; for turkies, though corn fed, delight in a variety of plants, such as cabbage, lettuce, endive, &c.; and poultry pick much grass; while geese live for months together on common by grazing alone.

Naught is useless made.

---

On the barren heath  
The shepherd tends his flock; that daily crop  
Their verdant dinner from the mossy turf  
Sufficient; after them, the cackling goose,  
Close-grazer, finds wherewith to ease her wants.

Attempts have frequently been made to domesticate these birds, by hatching their eggs in dove-houses under the common pigeon; but as soon as the young ones were able to fly, they always escaped to their proper haunts. Mr. Montagu was at considerable pains in endeavours of this nature; and though he so far tamed them within doors, as to have them become exceedingly troublesome, yet he never could produce a breed, either by themselves, or with the tame pigeon. Two bred up together with a male pigeon, were so tame as to eat out of the hand; but as they shewed no signs of breeding in the spring, they were, in the month of June, suffered to take their liberty, by the window of the room being left open in which they were confined. It was supposed, that the pigeon might induce them to return to their usual place of abode, either for food or to roost; but from that moment they assumed their natural habits, and nothing more was seen of them, although the pigeon remained.—This gentleman bred up a curious assemblage of birds, which lived together in per-

## P I G E O N

fect amity: it consisted of a common pigeon, a ring-dove, a white-owl, and a sparrow-hawk; and the ring-dove was master of the whole.

About the beginning of winter, the ring-doves assemble in great flocks, and leave off cooing. The multitude thus collected during that season, is so disproportioned to those which continue here the whole year, as to render it certain that much the greater part of them quit the country in the spring. It is most probable that these go into Sweden and the adjoining countries, to breed; and return thus far southwards in autumn, from being unable to sustain the rigours of that climate in the winter months. They again begin to coo in March; soon after which those that are left among us commence their preparations for breeding.

*The passenger-pigeon* is about the size of the common pigeon. Its bill is black. Round the eyes there is a crimson mark; and the head, throat, and upper parts of the body, are ash-coloured. The sides of the neck are of a glossy variable purple. The fore part of the neck and breast are vinaceous; and the under parts are the same, but paler. The tail is tolerably long. The legs red, and the claws black.

The passenger-pigeon visits the different parts of North America, in enormous flocks. In the southern provinces their numbers depend greatly on the mildness or severity of the season; for in very mild weather, few or none of them are to be seen. Actuated by necessity, they change their situations in search of acorns, mast, and berries, which the warmer provinces yield in vast abundance. When they alight, the ground is quickly cleared of all esculent fruits; to the great injury of the hog, and other mast-eating animals. After having devoured every thing that has fallen on the surface, they form themselves into a great perpendicular column; and fly round the boughs of trees, from top to bottom, beating down the acorns with their wings; and they then, in succession, alight on the earth, and again begin to eat.

“ I think (says Mr. Blackburn, in a letter to Mr. Pennant) that these are as remarkable birds as any in America. They are in vast numbers in all parts; and have been of great service, at particular times, to our garrisons, in supplying them with fresh meat, especially at the out-posts. A friend told me, that in the year in which Quebec was taken, the whole army were supplied with this subsistence, if they chose it. The way was this. Every man took his club (for they were forbid to use their firelocks), when they flew, as it was termed, in such quantities, that each person could kill as many as he wanted. They in general begin to fly soon after day-break, and continue till nine or ten o'clock; and again about three in the afternoon, and continue till five or six: but what is very remarkable, they always fly westerly. The times of flying here are in the spring, about the latter end of February or the beginning of March, and they continue every day for eight or ten days; and again in the fall, when they appear at the latter end of July, or the beginning of August. The inhabitants catch vast quantities of them in clap-nets, with stale pigeons. I have seen them brought to the market at New York by sackfuls. People in general are very fond of them, and I have heard

## P I G E O N

many say that they think them as good as our common blue pigeon: but I cannot agree in this opinion; the flesh tastes most like our queest, or wild-pigeon, but is better meat. Sir William Johnston told me, that at one shot, with a blunderbuss, he killed *above a hundred and twenty*.

I must remark one singular fact: that, notwithstanding the whole people of a town go out a pigeoning, as they call it, they do not, on some days, kill a single hen bird; and, on the very next day, not a single cock (and yet both sexes always fly westerly): and when this is the case, the people are always assured that there will be a great quantity of them that season."

They were so numerous when La Honton was in Canada, that the bishop, he says, had been compelled more than once to *exorcise* them formally, on account of the damage they committed. Many of the trees were said to have had more pigeons on them than leaves, in this migration; and for eighteen or twenty days, it was supposed, sufficient might have been killed to supply food for a thousand men.

Mr. Weld, who very lately travelled through the States of North America, informs us, that a gentleman of the town of Niagara assured him, that once as he was embarking there on board a ship for Toronto, a flight of them was observed coming from that quarter; that as he sailed over the lake Ontario to Toronto, forty miles distant from Niagara, pigeons were seen flying over-head the whole way in a contrary direction to that in which the vessel proceeded; and that on his arriving at the place of his destination, the birds were still observed coming down from the north in as large bodies as had been noticed at any time during the whole voyage. Supposing, therefore, that the pigeons moved no faster than the vessel, the flight, according to this gentleman's account, must have extended at least eighty miles.

During their migrations, these pigeons are very fat. It is a singular fact, that Mr. St. John found in the craw of one of them some undigested rice, when the nearest rice-fields were at least 560 miles from his habitation. He naturally concluded that either they must fly with the celerity of the wind, or else digestion must be in a great measure suspended during their flight.

The Indians often watch the roosting places of these birds; and knocking them on the head in the night, bring them away by thousands. They preserve the oil, or fat; which they use instead of butter. There was formerly scarcely any little Indian town in the interior parts of Carolina, where a hundred gallons of this oil might not at any time be purchased.

By the colonists they are generally caught in a net extended on the ground; to which they are allured by tame pigeons of their own species, that are blinded, and fastened to a long string. The short flights and repeated calls of the shackled birds, never fail either to excite their curiosity, or bring some of them down to attempt their relief; when they are immediately inclosed. Every farmer has a tamed pigeon in a cage at his door all the year round, to be ready against the season of their flight.

## P I G E O N

M. du Pratz, when he was in America, placed under their roosting-trees vessels filled with flaming sulphur, the fumes of which brought them to the ground in immense numbers.

In 1803, a trial to ascertain the velocity of the pigeon's flight was made by a gentleman near Manchester Square, who sent a pigeon to Salisbury, with directions for its being released, with a billet round its neck, precisely at twelve o'clock the day following. The bird arrived at seven minutes past three, a distance of eighty-three miles in three hours and seven minutes, or at the rate of twenty-six miles per hour.

The recent flights of pigeons from London to Antwerp must be fresh in the recollection of the reader; but as far as relates to their velocity, flights of this description afford no criterion, as a considerable period must elapse, on throwing up the pigeon, before the bird can ascertain its direct course. Hence it may reasonably be concluded, that the velocity of this bird's flight is much greater than it is generally supposed; or, at least, than has been hitherto stated.

The management of pigeons has been recently and fully treated of. After recommending the harvest flight of pigeons as the most proper for the purpose of stock, from being the strongest to withstand the winter season, the author of the "Experienced Farmer" gives the following directions:—"In regard to feeding them, it is only deemed needful between seed-time and harvest, when it should be done by three or four o'clock in the morning; if fed much later they will keep hovering about home, and be prevented from taking their necessary exercise. If fed the year round, pigeons will not breed nearly so well as if forced to seek their own food; for they pick up in fields what is pleasant and healthy to them, and from the beginning of harvest to the end of seed-time they find plenty. They may be fed with tares, grain, or seeds of any kind. Be cautious of not letting the first flight fly to increase the stock, but let every one of them be taken; as these will come in what is called benting-time, that is, between seed-time and harvest. It is then that pigeons are the scarcest; and many of the young ones would pine to death through weakness during that period. At the latter end of every flight, care should be taken to destroy all those eggs that are not laid in a proper time. The proper time for the spring flight is in April and May. After the harvest flight, cold weather comes on, which injures the old pigeon much if she sits late; and the young will be good for nothing if hatched. It is very necessary to pay attention to cleanliness in the management of a dove-cote. Before breeding time, the holes ought to be carefully examined and cleaned; for if any of the young die in the holes in summer, they become putrid, and emit a disagreeable and unwholesome stench, which is very injurious. Pigeons are tenacious of their nests, (as appears from the conduct of the wood-pigeon, which will breed for years in the same tree) and the female forsakes it with regret; but, unable to endure the filth and stench of her dead offspring, she is obliged to quit the eggs she laid for a second brood, and the prime of the season is lost.

"Every summer, immediately after the first flight, the nests

gevity of the pike is very remarkable. Gesner goes so far as to mention a pike whose age was ascertained to be 267 years.

Pike spawn in March or April. When they are in high season, their colours are very fine, being green, spotted with bright yellow, and having the gills of a most vivid red. When out of season, the green changes to grey, and the yellow spots become pale. The teeth are very sharp, and are disposed in the upper jaw, on both sides of the lower, on the roof of the mouth, and often on the tongue. They are altogether solitary fish, never congregating like some of the other tribes.

Ireland is remarkable for abundance of pike, and for the size to which they arrive in its waters; in the river Shannon and in Lough Corrib they have been found nearly seventy pounds weight.

Small fish shew a similar uneasiness at the presence of the pike, as the little birds do at the sight of the hawk or owl; and when they lie dormant near the surface, (as they frequently do in sultry weather) the lesser fish swim around in vast numbers, and with evident anxiety. Pike are often taken, in the hottest part of the days in summer, while they are thus asleep, by a noose of wire, fixed to a strong pole about four yards long; by which the wire with great slowness is conducted over the pike's head and gill fins, and then hoisted with a jerk to land.

Pike are also frequently shot while thus basking themselves: the marksman aims directly under them: from the deception there is in the water, and its causing the shot to rise much when fired into, he would otherwise miss his object.

Pike love a still, shady, unfrequented water, with a sandy, clayey, or chalky bottom, (arriving at a larger size in pools than rivers) and from May to the beginning of October, they usually place themselves amongst or near flags, bulrushes, and water-docks, and particularly under the *ranunculus aquaticus* when in flower, and which floats on the surface; they will sometimes be found in the termination of sharp currents: from March to the end of May they resort to back waters that have direct communication with the main stream: as winter approaches they retire into the deeps, under clay banks, bushes impending over the water, stumps and roots of trees, piles of bridges, and flood-gates. They spawn in March or April, according to the coldness or warmth of the weather, quitting the rivers for the

creeks and ditches communicating with them, and there dropping their ova in the grass and reeds; in ponds they choose the weeds upon the shallows for depositing it; ducks and other wild fowl eagerly devour the spawn, and by them it is transported to other waters. The appearance of the pike in ponds, where none were ever put, has been deemed as extraordinary as its asserted longevity; it is however easily accounted for, upon the well-known principles of the generation of fishes: if a heron has devoured their ova, and afterwards ejected them, while feeding in one of these ponds, it is highly probable that they may be produced from this original, in the same way as the seeds of plants are known to be disseminated.

Pike are in season from May to February, (the female fish are to be preferred;) are bold biters, afford the angler good sport, and may be fished for all the year; but the best months (especially for trolling) are February, before the weeds shoot, and October, when they are rotted; the latter is to be preferred, as the pike are fattened by their feed during the summer, and from the lowness of the waters, their harbours are easily discovered.

For trolling, the rod should be twelve or fourteen feet long; but a strong top for this fishing, with a ring at the end for the line to run through, may be fitted to a fly or general rod; there should be one ring upon each joint to conduct the line, which is better than a greater number, (and these rings must be set on straight, that it may run freely, so that no sudden check after the bait is taken prevent the pike from gorging it :) the line should be of silk, with a swivel at the end to receive the armed wire or gimp, and at least thirty yards long, wound upon a winch or reel, fixed to the butt end of the rod, hooks for trolling, called dead gorges, and other sorts for trolling, snap, and trimmer, and fishing needles, are to be bought at every shop where fishing-tackle is sold; in the choice of the first, let them not be too large, nor their temper injured by the lead on the shanks, nor the points stand too proud; and, although usually sold on wire, it is recommended to cut off the wire about an inch from the lead, and with double silk, well waxed, fasten about a foot of good gimp to the wire, with a noose at the other end of the gimp, large enough to admit the bait to pass through, to hang it upon the line. The best baits are gudgeons or dace, of a middling size; put the baiting-needle in at the mouth,

and out at the middle of the tail, drawing the gimp and hook after it, fixing the point of the hook near the eye of the fish; tie the tail to the gimp, which will not only keep it in a proper position, but prevent the tail from catching against weeds and roots in the water: thus baited, the hook is to be fastened to the line, and dropt gently in the water, near the sides of the river, across the water, or where it is likely pike resort; keep the bait in constant motion, sometimes letting it sink near the bottom, and gradually raising it; the angler need not make more than two or three trials in a place, for if a pike be there, he will within that time bite, if he means to do so; when the bait is taken, if at a depth too great to see, it will easily be ascertained by the line being drawn tight, and by some resistance: let the pike have what line he chooses, it will be soon known when he has reached his harbour by his not drawing more; allow from five to ten minutes, for his gorging the bait; wind up the line gently until the pike is seen, (which he will permit, though he has not gorged:) should the bait be across his mouth, give more time; but if he has swallowed, manage him with a gentle hand, keeping him however from roots and stumps, which he will try to fasten the line upon; in clear water veer out line until he is sufficiently tired, and a landing net can be used; but by no means, however apparently exhausted, attempt to lift him out with the rod and line only; for the moment he quits the water, he will open his mouth, and from his own weight, tear the hook from his stomach; and the fish will be lost to the angler, although it must inevitably perish.

In trolling, the bait should never be thrown too far: in small rivers the opposite bank may be fished with ease, and the violence of its fall upon the water, in extensive throws, soon spoils the bait, by rubbing off its scales, and alarms the pike, instead of enticing him.

The bead hook is used by putting the lead into the mouth of the live bait and sewing it up; the fish will live some time, and, notwithstanding the lead, will swim with the support he receives from the line, with nearly the same ease as if at liberty: this is the most successful way of tempting the pike.

Pike are to be allured by a large bait, but a small one is more certain to take them: never suffer weeds to hang upon the hook or bait when recast into the water, and which cannot touch the sur-

face too softly. Always prefer a rough wind, and when the stream is clear, for trolling: pike never bite in white water after rain, &c. If a pike goes slowly up the stream after taking the bait, it is said to be a signal of a good fish.

“ I saw a very large fish (says Colonel Thornton) come at me, and, collecting my line, I felt I had him fairly hooked; but I feared he had run himself tight round some root, his weight seemed so dead: we rowed up, therefore, to the spot, when he soon convinced me he was at liberty, by running me so far into the lake, that I had not one inch of line more to give him. The servants, foreseeing the consequences of my situation, rowed with great expedition towards the fish, which now rose about seventy yards from us, an absolute wonder! I relied on my tackle, which I knew was in every respect excellent, as I had, in consequence of the large pike, killed the day before, put on hooks, and gimp, adjusted with great care; a precaution which would have been thought superfluous in London, as it certainly was for most lakes, though, here, barely equal to my fish. After playing him for some time, I gave the rod to Captain Waller, that he might have the honour of landing him; for I thought him quite exhausted, when to our surprise, we were again constrained to follow the monster nearly across this great lake, having the wind, too, much against us. The whole party were now in high blood, and the delightful *Ville de Paris* quite manageable; frequently he flew out of the water to such a height, that though I knew the uncommon strength of my tackle, I dreaded losing such an extraordinary fish, and the anxiety of our little crew was equal to mine. After about an hour and a quarter's play, however, we thought we might safely attempt to land him, which was done in the following manner: Newmarket, a lad so called from the place of his nativity, who had now come to assist, I ordered, with another servant, to strip and wade in as far as possible; which they readily did. In the mean time I took the landing net, while Captain Waller judiciously ascending the hill above, drew him gently towards us. He approached the shore very quietly, and we thought him quite safe, when, seeing himself surrounded by his enemies, he in an instant made a last desperate effort, shot into the deep again, and, in the exertion, threw one of the

men on his back. His immense size was now very apparent; we proceeded with all due caution, and, being once more drawn towards land, I tried to get his head into the net, upon effecting which, the servants were ordered to seize his tail, and slide him on shore: I took all imaginable pains to accomplish this, but in vain, and I began to think myself strangely awkward, when at length, having got his snout in, I discovered that the hoop of the net, though adapted to very large pike, would admit no more than that part. He was, however, completely spent, and, in a few moments, we landed him, a perfect monster! He was stabbed by my directions in the spinal marrow, with a large knife, which appeared to be the most humane manner of killing him, and I then ordered all the signals, with the sky-scrapers, to be hoisted; and the whoop re-echoed through the whole range of the Grampians. On opening his jaws, to endeavour to take the hooks from him, which were both fast in his gorge, so dreadful a forest of teeth, or tushes, I think I never beheld: if I had not had a double link of gimp with two swivels, the depth between his stomach and mouth would have made the former quite useless. His measurement, accurately taken, was five feet four inches, from eye to fork.

On examining him attentively, I perceived that a very large bag hung deep below his belly, and, thinking it was lower than usual with other pike, I concluded that this had been deeply fed but a short time before he was taken. After exhibiting him, therefore, to several gentlemen, I ordered that my housekeeper, on whom I could depend, should have him carefully opened the next day, and the contents of his stomach be reserved for inspection; and now ordering the servants to proceed with their burden, we returned to Avemore, drank tea, and afterwards went on to the Raits, where we produced our monster for inspection, to the no small gratification of the spectators, whose curiosity had been strongly excited to view a fish of such magnitude.

Agreeable to the orders of the preceding day, Mrs. C. opened the pike, and sent to us the contents of his stomach, which, to our surprise, consisted of part of another pike half digested. The tumour, or bag, arose from his having, no doubt many years since, gorged a hook, which seemed to us better calculated for

sea than for fresh-water fishing. It was wonderfully honey-combed, but free from rust, so that I cannot doubt of its having been at least ten years in his belly. His head and back bone I ordered to be preserved in the best manner I could devise, and the rest to be salted down.

The weight of this fish, judging by the trones we had with us, which would only weigh twenty-nine pounds, made us, according to our best opinions, estimate him at between forty-seven and forty-eight pounds. I had before this seen pike of thirty-six pounds, and have had them at Thornville of above thirty; but the addition of seventeen pounds and a half made this quite a different fish. There may be larger pike, but I cannot readily credit the accounts of such until I receive more authentic information." This extraordinary fish was taken in Loch Alva, in the Highlands of Scotland.

The next pike in size to the foregoing, taken by the troll, was in December, 1792, by Mr. Bint, in the pool at Packington, (the Earl of Aylesford's) being from eye to fork two feet eleven, full length three feet ten and a half; circumference one foot ten inches, and weighed thirty-four pounds and three quarters.

In 1804 a pike was taken out of the same water, with a carp, that weighed ten pounds, stuck in his throat, and which had choaked him. The pike when empty was thirty pounds weight.

Mr. Wilson caught a pike by trolling in the Driffeld Canal, near Brigham, which weighed twenty-eight pounds, measured two feet round the belly, and three feet five inches in length; and what was singular, five pounds of solid fat were taken out of his inside.

Sir Cecil Wray's pike, caught in June, 1799, at the draining off the water from the lake at his seat at Summer Castle, in Lincolnshire, weighed forty-seven pounds gross, thirty-six pounds, after being cleaned, of eatable meat; was forty-eight and a half inches long, and two feet two inches in circumference: this fish must have got into the lake when very small, and had acquired this enormous size in twenty-two years; for at that time the lake was laid dry. Sir Cecil computes that he consumed three fish per diem, progressively larger as his own size increased, and that he at least destroyed 24,000; all of which, in the latter years of his growth, must have been valuable fish; so that the cost of his support exceeded, by some hundred times, his own

value. A river pike grows fast until he arrives at twenty four inches; he then ceases to extend so rapidly in length; (for, in good water, with plenty of feed, a pike spawned in March will, by the March following, be grown from sixteen to eighteen inches,) and proportionably thickens; afterwards he will be much longer arriving at his full bigness, (which is about forty-six inches,) from the length of thirty, than he was in acquiring the first thirty inches.

In May, 1706, Mr. Bishop of Godstow, between Weir and Wytham Brook, landed the largest pike ever remembered to be taken in the Isis; it was four feet two inches long, two feet ten in girth, and, after being disgorged of a barbel nearly six, and a chub upwards of three, pounds, weighed thirty-one pounds and a half.

In June, 1796, a male pike was caught in Exton Park pond, (Lord Gainsborough's,) the length forty-two and a half from eye to fork, and from nose to tail forty-nine inches; the girth twenty-eight inches, and weighed thirty-seven pounds and a quarter. Neither this, nor the fish taken in the Isis, was so well grown as Sir Cecil Wray's.

In 1797 a pike, weighing near forty pounds, and measuring in length three feet six, and in girth two feet, was caught in a pond at Totteridge, in Hertfordshire; a tench of four pounds, and four pounds and a half of solid fat, were taken from his inside.

In Munden Hall Fleet, a pike was found that had been killed by a very long frost; in its putrid state it weighed forty-two pounds, but had wasted considerably; was three feet six long, and two feet nine inches in girth; the teeth were nearly as long, though not so stout, as those of a greyhound: the head of this fish was dried with the skin on, and long preserved at the hall as a great curiosity, not only on account of its immense size, but from a peculiarity in the lower jaw, which had bristles like those growing on the breast of a turkey-cock, proceeding from the under part of it. This head was given to the Rev. Mr. Kay, of South Bemfleet, in Essex, by Mr. Lugar; and from Mr. K's house some friendly collector of natural curiosities took the opportunity of marching off with it, during a very severe illness with which that gentleman was afflicted in the year 1792\*.

In some places pike are taken by what is termed dipping; the hook used is a large sized gorge hook, very slightly leaded on the shank, and baited as in trolling, only the mouth of the fish is to be sewed up, and the back fin cut away, and then looped to the swivel; the line is let out from the reel to a convenient length, and the bait is dropped in any small openings where the water is not very deep, and overspread with docks and weeds. The fish hanging with his head downwards will, when gently moved, (and all baits, especially dead ones, should be kept in constant motion,) shoot and play about among the weeds so naturally, that the pike will be eager in taking it this way, even from the surface: when the bait is seized, the line is to be slackened, and the pike allowed line to run; in a short time it will be perceived to shake, which is a signal to strike; when hooked, he must be cautiously managed, winding up the line gradually: in getting the pike through the weeds, endeavour to keep his nose above them, and use the landing-net in taking him from the water. In this method the baits must be as fresh as possible.

For snap-fishing, (which is best used in March, the pike being then very shy of gorging, although with seeming eagerness they seize the bait,) should the rod be purposely made for it, the length should be about twelve feet; if a common rod is employed, the top should be stouter than that used in trolling, with a strong loop to fasten the line upon, which must be a foot shorter than the rod: for the live snap, no hook is so proper as the double spring hook: to bait it, nothing more is requisite than to hang the fish to the small hook under the back fin, which

Barcomb Mills, a dead pike of an extraordinary size, jammed between a willow stump and the bank. In length it measured, from eye to fork, four feet, was one foot thick across the back, and weighed, in its wasted state, forty pounds. This confined situation of the fish is attributed to the rapidity of the current forcing it into a position from which it could not after extricate itself, and consequently there remained till it was literally starved to death.

At Shardeloes, the seat of Mr. Drake, is a good painting by Francis Barlow, of a pike caught in the lake before the house, which weighed thirty-four pounds.

\* In January, 1803, the gamekeeper of Mr. Shiffner, of Comb Place, near Lewes, in Sussex, discovered in the Lewes river,

may be done with so little hurt to the fish that it will live for many hours. Gudgeons (which, in all modes of pike-fishing, are superior to every other) and dace are the best baits; they must be kept alive in a tin kettle, with holes in the lid, and which in hot weather should be placed in the water.

The other live snap-hook is baited by the small hook being thrust through the fish beneath the back fin; and some use a piece of silk or thread doubled, hung on the point of the small hook, and brought under the belly of the bait, and tied on the other side to the shanks of the large hooks; care and expedition are required in doing this, otherwise the bait will be so injured as to be incapable of swimming briskly in the water: a cork float, the size of a common burgamot pear, with a small pistol bullet or two, not only to poise, but to keep, the bait at a proper depth, which is from two to three feet. If a pike be near where the bait is put in, it will come to the surface, or increase the quickness of its motion to avoid him; these signs will put the angler on his guard: when the float is drawn under, allow it to be sunk considerably before striking, which, in all snap-fishing, should be with a smart stroke, and directly contrary to the course the pike appears to take; the line must be kept tight, and the landing net should be used, as the throwing out a large pike by force will certainly strain the sockets of the rod.

Some use only one large long-shanked hook, whipped to gimp, with a swivel at the upper end; the hook baited with a gudgeon under the back fin, or through the upper lip, with a float as above, that will swim the gudgeon; fish at mid-water, and allow a minute after the float is sunk before striking: by this method perch may be taken, if the bait be a minnow or very small gudgeon.

A variety of hooks are used for the dead snap; and this mode of catching pike is well adapted to both shallow and deep waters, to the still rapid parts of the river; will take pike at all seasons of the year, supposing the water and weather favourable; and it will be no trifling recommendation that the idea of cruelty, which the use of a live fish naturally impresses, is, by this substitute, completely removed. The rod should be longer than that for trolliug; the line fine, strong, and twenty yards in length; the hook by some most preferred is like that for a common live snap; the length of the

gimp, on which the hook is tied, should be regulated by the size of the bait, and should be rather longer than the distance from the back fin to the mouth; that the looped end may be hung on a strong swivel, tied neatly to about a foot more of gimp, with a noose at the other end, to hang it upon the line, fastening a piece of lead, of the shape of a barley-corn, and weighing about an ounce, with a hole through it, about two inches above the swivel. The bait should be a middle sized dace: insert the baiting needle close behind the back fin, letting it come out of the mouth; draw the gimp to which the hook is tied after it; the short hook must stand with the point upright behind the back fin; the others will consequently be on each side; then hang it upon the swivel, and try if it will spin: if it does not, move the bait a little to the right or left, which may be done without moving it from the hook: the whole success depends on its quick turning when drawn against the stream; and when it does, it appears like a fish unable to escape, and becomes too tempting a morsel for the pike to resist: this method will not only enable the angler to fish a greater extent of water than the others, but is more certain to secure the pike. The large ones, though bold in seizing the bait, are very cautious in gorging it: most trollers have experienced, that, after running out a considerable length of line, the bait has been mumbled to pieces and deserted; a disappointment here remedied, for a pike has but to seize the bait, and he is caught.

At both troll and snap, some persons have two or more swivels to their line; by which means its twisting is prevented, the bait plays more freely, and to the dead bait in rivers it certainly is an improvement: in ponds or still waters one will answer the purpose.

Another way of taking the pike is with an artificial fly: many have asserted that they are not to be caught at all with a fly, but, as a convincing proof to the contrary, a pike, the largest taken by a line, or perhaps ever known in this country, was caught in Loch Ken, near New Galloway, in Scotland, with a common fly, made of the peacock feather; it weighed seventy-two pounds; the skeleton of the head is at Kenmore Castle; the jaw at the top is that of a pike, weighing twenty-five pounds: a scale is annexed by which the respective proportions of the two may be ascertained, and which will

convey some idea of the largest pike ever seen in Great Britain.

The pike fly must be made upon a double hook, fastened to a good link of gimp, and composed of very gaudy materials ; such as pheasant's, peacock's, or mallard's feathers ; the brown and softest part of bear's fur ; the reddish part of that of a squirrel, with some yellow mohair for the body. The head is formed of a little fur, some gold twist, and two small black or blue beads for the eye ; the body must be framed rough, full, and round ; the wings not parted, but to stand upright on the back, and some smaller feathers continued thence all down the back, to the end of the tail ; so that, when finished, they may be left a little longer than the hook, and the whole to be about the size of a wren. A fly thus made will often take pike, when other baits are of no avail, especially in dark windy days ; the fly must be moved quick when in the water, and kept on the surface if possible. Several sorts of these flies are to be had at all the fishing-tackle shops.

Pike are also taken with a live bait, fixed to a certain place, termed a ledger bait : if a fish is to be used, the hook is to be run through the upper lip or back fin ; if a frog (of which the yellowest are the best,) the arming wire is to be put in at the mouth, and out at the gill, and tie the leg above the upper joint to the wire ; fasten the wire to a strong line, about twelve or fourteen yards long ; the other end being made fast to a stake or stump of a tree, a forked stick is to be placed near the surface, through which the line is to pass, and suspend the bait about a yard in the water, by a notch made in the fork ; but which, when the bait is taken, will easily slip out ; but the best way is to have a wheel, or an iron spindle, to stick into the ground.

Huxing pike is, with large bladders, blown up and tied close ; at the mouth of each fasten a line, (longer or shorter according to the water's depth,) with an armed hook baited ; launch them with the advantage of the wind to move up and down the pool : a boat will be necessary in this diversion.

Huxing pike is also done by fixing an armed hook baited, at such a length as to swim about mid-water, to the leg of a goose or duck, and then driving the birds into the water. It was thus formerly practised in the Loch of Monteith, in Scotland, which abounds with very large perch and pike. "Upon these islands a

number of geese were collected by the farmers, who occupied the surrounding banks of the loch : after baited lines of two or three feet long had been tied to the legs of their geese, they were driven into the water ; steering naturally homewards, in different directions, the baits were soon swallowed : a violent and often tedious struggle ensued ; in which, however, the geese at length prevailed, though they were frequently much exhausted before they reached the shore." This method has not been so long relinquished but there are old persons upon the spot who were active promoters of the amusement.

Trimmers of two sorts may be described, the one is made of flat cork, or any light wood, painted, to be seven or eight inches diameter, turned round with a groove in the edge, large enough to receive a fine whipcord or silk line, twelve or fourteen yards, or at least five yards longer than the depth of the water : a small peg, two inches long, is fixed in the centre, with the end slit ; and a small double hook fixed to a brass-wire link is to be used. Insert the baiting needle under the side-fin of the bait, (for which large gudgeons are superior to all others,) and keep it just within the skin of the side ; bring it out beyond the back fin, drawing the wire after it, and the hook, when drawn home, will be partly covered by the side fin. This method, performed carefully, will preserve the fish alive for many hours longer than any other ; one end of the line is of course fixed to the cork, the other to the loop in the wire ; the line is then slightly put into the slit of the peg, to keep the bait at a proper depth, (from three to four feet, which is more likely to attract the pike's notice than if it laid deeper, or nearer the surface,) and to prevent its untwisting the line out of the groove. The trimmer should always be started on the windward side of the pond, and the rougher the water the better sport ; if not seized in one trip, it must be taken up and re-started from the windward side again.

The other trimmers are also of cork, and are to be baited and used as above ; their form is adapted to go easily through weeds when taken by the pike ; after the line is run off, they will follow in the shape of a wedge, and will not long be kept from appearing on the surface in the weediest places : a hole is burnt through one corner of the cork, by which, with a cord, it may be made stationary to the

side of any water ; and which method is sometimes preferred where a boat cannot be readily commanded. No species of fishing does more execution than this : in windy weather, at all seasons of the year, and both day and night, the trimmer presents itself as the most deadly foe the pike can encounter.

Pike, in clear water and a gentle gale, from the middle of summer to the latter end of autumn, bite best about three in the afternoon ; in the winter, during the whole day ; and in the spring, most eagerly in the morn, and late at eve.

PILOT. There have been three horses of this name ; two of which were excellent racers, and esteemed equal, as plate horses, to any of their time. The first was bred by Sir Charles Bunbury ; foaled in 1762 ; got by Snap, dam by Cade, grand-dam by Crab, out of Lord Portmore's Abigail. The second was bred by Sir H. Harpur ; foaled in 1770 ; got by Dainty Davy, dam by Blanck, grand-dam (Dizzy) by the famous and original Driver. The third was bred by the late Counsellor Lade ; foaled in 1782, and got by the above, dam by Marske, grand-dam by Regulus. The two last won a great number of fifty-pound plates annually for several years in succession, and afterwards proved very excellent country stallions.

PINCHING. In jockeyship, a term used to express a method of trying a horse's mettle, or vigour, and of shewing him off to a purchaser when the creature is on sale. Thus, when the rider is on his back, he makes him stand still, and keeping him fast with the bridle-hand, he applies the spurs to the hair of the horse's sides. If the horse is impatient under this, and draws himself up, and wants to go forward, it is a sign of mettle. But the purchaser ought to try this himself on the horse's back ; for the jockeys have the art of making the dullest horse seem to have mettle in these trials. The purchaser must also distinguish between the restlessness of the horse, under this treatment, that arises from vigour, and that which arises from the horse's being ticklish, and which goes off immediately.

PINTAIL, THE. This bird is less than the wild duck ; its length is twenty-eight inches, breadth thirty-eight, and its weight twenty-four ounces.

The form of the pintail is slender, and the neck long ; bill long and black, on the sides blueish ; the head, for an inch of the neck before, rusty purplish brown ;

nape dusky ; forepart and sides of the neck white, a little mottled with dusky, the white rising upwards on each side at the back part like ribbands ; part of the neck, and back, greyish white, finely barred with black ; sides of the body the same, but paler ; scapulars black, long, pointed, and margined with very pale cream-colour ; wings pale dusky brown ; across them, first a pale rufous bar, then a broad deep copper-coloured one, edged with black, and below this is a narrow one of white ; the two middle tail feathers are black, and more than three inches longer than the rest, and end in a point ; the exterior feathers of the tail are ash-coloured ; the under parts of the body are white ; vent black, the sides of it white ; legs and feet small and lead-coloured.

The female is smaller ; head and neck dusky, minutely streaked with brown, spotted with black ; tail as in the male, but the two middle feathers not so far elongated.

This species is pretty common during winter in England, especially in severe weather, when it is very fat ; the flesh is superior in its delicate flavour to any other wild fowl. In the month of February only these birds are found in great abundance in Connaught, in Ireland. Upon the continent, in the northern parts of which it breeds, it is extremely numerous. It is abundant at the Lake Baikal, in Asia, and is often seen in large flocks on the sea-coasts of China, where it is caught in snares. In America it is not uncommon, being plentiful at New York, where it is called blue-bill ; from thence it is found as far north as Hudson's Bay, where it is supposed to breed.

PISTE. In the manege, the tread or track that a horse makes upon the ground he goes over. The language is, " This horseman observes the piste, and makes it his business to follow the tread ; " that is, he follows his ground regularly, without enlarging or narrowing, without traversing or entangling : such a horse " works well upon two treads ; " he works well with one piste.

PLANTED. A term used of a horse. He is said to be well planted when he stands equally firm on all his legs, and not with one advanced before the other. His legs should be wider above than below, that is, the distance between his feet should be less than between his fore thighs, at that part next to the shoulders ; the knees ought not to be too close, but the whole leg should descend in a straight

line to the very pastern-joint, and the feet should be turned neither out nor in, the pastern being placed about two fingers breadth more backwards than the coronet. As for his make behind, his hams should not be too close, and the instep, which is betwixt the hock and the pastern-joint, should stand perpendicular to the ground.

**PLAY OR PAY.** A description of bet so made. Whether the subject of such bet be man or horse; the object of a race, or boxing match; either party being present at the time and place appointed, ready to perform their part of the engagement previously entered into; the other not appearing, or appearing and then and there refusing to enter into the contest, upon the event of which the article or bet was originally formed, can lay no claim whatever to the stakes deposited; and the holder stands justified in handing such stakes over to the winner, having sufficient evidence in justification on his own part, to prove that it was *bona fide* a "play or pay" bet.—Or, supposing a bet to be made upon a horse which happens not to start, the person who backed the said horse must pay.

**PLAY OR PAY.** The name of a horse of much racing celebrity, the property of Mr. Durand. He was bred by Mr. Parker, and got by Ulysses out of Tiffany's dam. In 1794, at three years old (in the name of Mars) he won 50l. at Epsom, beating six others. At Stockbridge, a sweepstakes of 10gs. each, nine subscribers. At Winchester, he walked over the course for a sweepstakes of 20gs. each, eight subscribers. In 1795, when four years old, he beat Mr. Turner's Tim Tartlet, two miles for 200gs. The next day he beat Mr. Cauty's Alderman, two miles, for 50gs. He won also 50l. at Guildford; a sweepstakes of 15gs. each at Stockbridge, seven subscribers: the next day, a sweepstakes of 10gs. each, six subscribers. At Winchester, a sweepstakes of 10gs. each, eight subscribers. At Egham, he walked over for a sweepstakes of 10gs. each, five subscribers. The next day, he won a 50l. plate, beating Pandolpho and Serpent. In 1796, when five years old, he won the Craven stakes, of 10gs. each, at Newmarket, beating eleven others: 50l. at Ascot Heath. In 1797, then six years old, he won 50l. at Epsom, beating five others: 50l. at Lewes, beating Gohanna and Keren-happuch: 50l. at Abingdon, beating Keren-happuch, Paroquet, and Roland. In con-

sequence of having been so hard run for four years in succession, he started seven times in 1798 without once winning. In 1799, he won 50l. at Epsom, beating Yeoman and Midnight: 50l. at Guildford, beating Mr. Lade's David, and two others: and 50l. at Egham, beating Lord G. Cavendish's horse by Jupiter: after which, he was purchased by Mr. Dashwood, in whose possession, at nine years old, in 1800, he beat Mr. Whaley's Post Boy, four miles, over Ascot, for 100gs. and walked over at Egham for a sweepstakes of 20gs. each, three subscribers.

**PLEURISY, PERIPNEUMONY, or INFLAMMATION OF THE LUNGS** is a common, and one of the most dangerous disorders that can happen to a horse; inasmuch, that if nothing has been done in this malady, it is hardly possible to save his life after three days have elapsed. The disorder once excited, various effects will be produced, according to the diversity of the parts affected: for inflammation of the lungs inflames the contiguous extremities of the pulmonary artery. When these are inflamed, the blood becomes stagnant, the vessels are distended, the thinnest part of the fluids is expressed, as it were by transudation, and the thicker parts are accumulated; and all the blood, as yet capable of circulation, is collected between the right ventricle of the heart, and the extremities of the pulmonary arteries. Hence the lungs become oppressed, incapable of expanding; and, after death, the right ventricle of the heart is found to have been inflamed; and, on some occasions, so much distended with blood, as actually to burst, and the lungs resemble putrid liver, the cells being filled with blood from the great distension of the pulmonary arteries. This effusion takes place in the cavity of the chest, often to the quantity of one and two buckets. In the beginning of the disease, the pulse is oppressed, from the great distension occasioned by the blood in the right side of the heart, while the left side of this viscus is weak, for want of a sufficient quantity. In the horse, peripneumony, pleurisy, &c. form only one and the same disease; although some of our latest veterinary writers have been pleased to make different chapters of each, after admitting the almost indistinguishable resemblance of the different diseases, and the necessity of recurring to the same treatment for them all.

*The Causes* of this disease, are a sudden change of temperature in the atmo-

sphere; the drinking of cold water, after being heated by exercise; or by exposure to a current of cold or damp air in the same state; swimming or washing the animal in a state of perspiration; high feeding, and want of regular exercise; and lastly, that blind notion of keeping the stables too hot; for nothing contributes so much to the generation of diseases of all kinds, as shutting up horses in warm and confined stables, where every door and window, and every crevice of the stable is closed up (as if the external air was infectious); by which means they constantly breathe a loathsome, strong, hot, foul air, highly impregnated with the putrid steams of their own urine, dung, &c. and every hurtful exhalation produced by the great heat of the confined air. Such a situation as this unavoidably brings the system into a completely relaxed state: the lungs being deprived of a free circulation, the animals are exposed to all kinds of distempers, which take place in consequence of obstructed perspiration; such as tumours in the glands, lumps, swelled legs, the grease, mange, farcy, inflammation of the eyes, and even the glanders. But the danger is infinitely greater when the perspirable matter, intended to be carried off in the ordinary course, fixes itself upon some internal viscus, such as the brain, the lungs, pleura, intestines, &c. From the first arise all the diseases of the brain, such as staggers, apoplexy, &c. From the second, coughs, inflammation of the lungs, consumption, &c. And in the third place, should the perspirable matter fix upon the bowels, a diarrhoea will be the consequence, which generally terminates with more or less fatal effect.

The danger of an inflammation of the lungs is in proportion to the degree of fever, which may be easily ascertained by the following invariable symptoms, viz. quick respiration; hot breath; the extremities cold; the tongue hot and dry; the flanks heaving; the animal never lying down; the last forms a very characteristic symptom: he also sometimes hangs his head.

*Treatment.* The most powerful means of resolution should be employed on the discovery of the disease; copious bleeding from a large orifice, or from opening the two jugular veins at once, is what we chiefly depend upon. In this operation, the quantity of five quarts may be taken at once, which answers better than the common practice of drawing three pints,

or two quarts, as practised by common farriers. Previous to bleeding, the pulse is oppressed; but it soon becomes strong and full, by the removal of the distension, by copious bleeding; but, if the evacuation be continued, it becomes weak.

We must endeavour also to bring an external irritation on each side of the chest and legs, by blistering or firing (or perhaps both) the region of the lungs; and at the same time introducing one rowel under the chest, and another under the belly. The four extremities are to be well stimulated with spirits of turpentine, twice a day; if this does not stop the progress of inflammation, we must stop the circulation in the veins by external pressure (or ligatures); and at the same time the cellular membrane, under the skin of the chest, must be inflated with air, so as to bring on inflammation; and if this does not succeed, we may inject some stimulating fluid, as spirits of turpentine, which is the best stimulus; this will be found one of the most salutary remedies in this fatal disease.

Internally, diuretics are sometimes used with advantage; such as an ounce or two of nitre made up into a ball, with a little treacle; at the same time giving the following balls, viz. tartar emetic, three ounces; opium, an ounce; treacle, sufficient quantity to be made into a mass; to be divided into twelve balls, one of which must be given in the morning, and another in the evening.

During this treatment we must inject two or three clysters of warm water every day; and the animal must also be kept in a cold stable, well clothed, taking care to allow a free circulation of air; in dry weather, indeed, an open field will be preferable to a stable. His drink must be of good warm gruel; and the animal must take no exercise during the inflammatory state of the disease. On the termination of inflammation of the lungs, a quantity of coagulated lymph is frequently left unabsorbed in the cavity of the chest; or a common anasarca of the lungs occurs from the inaction of the absorbent vessels, which had previously been excited too violently. This produces a cough, and a difficulty of breathing, which is sometimes cured by the use of a very powerful tonic; such as blue vitriol, and tartar emetic, of each three ounces, mixed with a small quantity of linseed powdered, and anisated balsam of sulphur, or Venice turpentine, sufficient quantity to mix the mass, to be divided into twenty-four balls,

given once or twice every day, according to circumstances, and continued as long as necessity requires. Should they act as a diuretic, or take the horse off his food, they must be discontinued for a few days; but when the staling is over, and the animal recovers his appetite, the medicines must be recurred to as before, until you have obtained a perfect and radical cure.

Blistering on each side of the chest will also be found very useful in promoting absorption. If the method of practice here recommended be judiciously employed, it will answer the highest expectations, in removing the inflammatory as well as chronic state of one of the most fatal disorders incident to the horse.

**PLOVERS.** There are three sorts of these birds which are very minor objects of the sportsman's pursuit; the golden, the grey, and the peewit or lapwing.

The golden plover is the size of the turtle dove; its weight nine ounces; length eleven inches, breadth twenty-four; the bill is short and black; the feathers on the head, back, and wing coverts, are dusky, beautifully spotted on each side with light yellowish green; round the eyes and the chin almost white; sides of the head, the neck, and sides of the body, the same as the upper parts, but much paler: the breast brown, marked with greenish oblong strokes; the middle feathers of the tail barred with black and yellowish green: the greater quills are dusky; the legs black; and it wants the back toe, by which it is distinguished from other birds of its kind. There is some variety seen in the colour of the belly; this is owing to the season: about the beginning of March, the appearance of black in the breast is first seen, increasing by degrees, until that part becomes a full black; but after the time of incubation, this tint again disappears, and the belly is white. The male and female differ very little, and in the young birds the spots are not of a full yellow, but incline more to grey.

M. Baillon, who has observed these birds in Picardy, asserts, that their early plumage is grey; that at their first moult in August and September, they get some feathers of a yellow cast, or which are spotted with that colour; but it is not until after some years that they acquire their fine golden tint. He adds, that the females are hatched entirely grey, and only when old assume a little yellow; and that it is very rare to see their feathers so uniform and beautiful as the males. No longer need the distinction of tints in this species of birds be remarked, since this gentleman has proved, that the varieties result from the difference of age and sex.

This elegant bird inhabits England the whole year, and breeds on several of our unfrequented mountains; is very common on those of the isle of Rum, and others of the loftier Hebrides; also on the Grampian, and all the heathy hills of the islands and Highlands of Scotland: millions are found in the Orkneys, from which they never entirely migrate; they lay four eggs, two inches in length, more pointed in shape than those of the lapwing, and of a pale cinereous olive, blotched with blackish spots; they make a whistling noise, and fly in small flocks, and, by a skilful imitation of the note, may be enticed within shot. They frequent, in November, meadows and commons; and there was once an instance of a warrener near Bristol killing eleven at one shot. Their flesh is sweet and tender; they

QUAIL, *p.* 671.

PARTRIDGES, *p.* 583.

## P L O V E R

are dressed like the woodcock, with their trail, and are excellent eating.

The golden plover is common in all the northern parts of Europe. It is numerous in America, from Hudson's Bay to Carolina; migrating from one part to another, according to the seasons: is met with to the south as far as Aleppo; and if, says Latham, the species be not mistaken, in the island of Batavia and in China. Our last voyagers found them at Owhyhee, Tongataboo, and also York Islands, but of a smaller size.

*The grey plover* is about twelve inches long and twenty-five broad, and weighs seven ounces; the bill is black, about an inch long: in the roof of the mouth is a double row of spinous appendages pointing inwards; the head, back, and wing coverts, are of a dusky brown, edged with greenish ash-colour, and some with white; the cheeks and throat white, marked with oblong dusky spots; the belly, thighs, and rump, white; the exterior webs of the quill feathers black; the lower part of the interior webs of the first four white: the tail is short, does not project beyond the wing, and is marked with transverse bars of black and white; the legs are of a dirty green; the back toe extremely small. This bird is in no great abundance, in England;\* they generally come in small flocks about October, and leave this country about March; in cold and frosty weather they seek their food on such lands as lie near the sea; in open weather they feed in ploughed fields, especially if sown; and, having fed, fly to some plash of water to wash their beaks and feet—a habit which is also common to the woodcocks, the lapwings, the curlews, and many other birds which feed on worms; they sleep chiefly in the day in calm weather, passing most of the night in running up and down after the worms, which then creep out of the ground: at that time they make a small cry, as if to keep their flock collected till day-break, when they unite and fly to the coast; they are sometimes taken in nets at their first coming, and the fowler is cautious to set his nets to play with the wind; for instance, when the wind is easterly that they may play westerly. The north-west is the worst wind to take them; all sea-fowl fly against the wind, whenever they design to rest on the land. The preferable places for setting the nets are in large common fields of green corn, and near to water, for there they are sure to resort to clean their beaks and feet: their flesh is very delicate. In Carolina they are seen in the valleys, near the mountains, in great numbers, but seldom alight; are also very common in Siberia, appearing there in autumn in vast flocks, coming from the extreme north, where they breed.

*The lapwing or plover.*—This bird is too well known to need any

---

\* Mr Gilpin speaks of them as sometimes abounding in the New Forest. "Plovers of different kinds (says that gentleman) are common in its heathy parts. I have sometimes seen large flocks of the grey species, and admired them as they encircled the air; in their regular flight they in some degree resemble water-fowls, but are not so determined in their course, wheeling about and forming various evolutions: at times they appear scattered and in confusion, until closing together, as if by some word of command, they get again into form."

## P L O V E R

description here. It is found in most parts of Europe, as far northward as Iceland. In the winter is met with in Persia and Egypt.

The chief food of the lapwing is worms; and sometimes they may be seen in flocks, nearly covering the low marshy grounds, in search of these, which they draw with great dexterity from their holes. When the bird meets with one of those little clusters of pellets, or rolls of earth, that are thrown out by the worms' perforations, it first gently removes the mould from the mouth of the hole, then strikes the ground at the side with its foot, and steadily and attentively waits the issue: the reptile, alarmed by the shock, emerges from its retreat, and is instantly seized. In the evening the lapwings pursue a different plan; they run along the grass and feel under their feet the worms, which now come forth invited by the coolness of the air. Thus they obtain a plentiful meal; and afterwards wash their bill and feet in the small pools or rivulets.

"I have seen this bird (says Dr. Latham) approach a worm-cast, turn it aside, and, after making two or three turns about, by way of giving motion to the ground, the worm came out, and the watchful bird, seizing hold of it, drew it forth."

They remain in England the whole year. The female lays four or five eggs among rushes, or upon fallows, upon a little bed which she prepares of dry grass. These are olive-coloured and spotted with black. She sits about three weeks, and the young are able to run within one day after they are hatched.

The parent exhibits the greatest attachment to them; and the arts used by this bird to allure boys and dogs from the place where they are running, are extremely amusing. She does not wait the arrival of her enemies at the spot, but boldly pushes out to meet them. When as near as she dare venture, she rises from the ground with a screaming voice, as if just flushed from hatching, though probably at the same time not within a hundred yards of her nest. She flies with great clamour and apparent anxiety; whining and screaming around the invaders, striking at them with her wings, and sometimes fluttering as if she was wounded. To complete the deception, she becomes still more clamorous as she retires from the nest. If very near, she appears altogether unconcerned, and her cries cease in proportion as her fears are augmented. When approached by dogs, she flies heavily, at a little distance before them, as if maimed; still vociferous, and still bold, but never offering to move towards the quarter where her young are stationed. The dogs pursue, in expectation every moment of seizing the parent, and by this means actually lose the young; for the cunning bird having thus drawn them off to a proper distance, exerts her powers, and leaves her astonished pursuers to gaze at the rapidity of her flight.

There are few readers acquainted in any degree with the country, who will not recollect how justly the following lines describe the manners of this bird:—

—————Hence, around the head  
Of wand'ring swains, the white wing'd plover wheels  
Her sounding flight; and then directly on,

## P O A C H E R

In long excursion, skims the level lawn,  
To tempt him from her nest.

The following anecdote exhibits the domestic nature of the lapwing, as well as the art with which it conciliates the regard of animals differing from itself, and generally considered as hostile to every species of the feathered tribe. Two lapwings were given to a clergyman, who put them into his garden ; one soon died, but the other continued to pick up such food as the place afforded, till winter deprived it of its usual supply. Necessity soon compelled it to draw near the house, by which it gradually became familiarized to occasional interruptions from the family. At length, one of the servants, when she had occasion to go into the back-kitchen with a light, observed that the lapwing always uttered his cry of “*pee-wit*” to obtain admittance. He soon grew more familiar : as the winter advanced, he approached as far as the kitchen, but with much caution, as that part of the house was generally occupied by a dog and cat, whose friendship, however, the lapwing at length conciliated so entirely, that it was his regular custom to resort to the fireside as soon as it grew dark, and spend the evening and night with his two associates, sitting close by them, and partaking of the comforts of the warmth. As soon as spring appeared, he discontinued his visits to the house, and betook himself to the garden ; but on the approach of winter, he had recourse to his old shelter and friends, who received him very cordially. Security was productive of insolence ; what was at first obtained with caution, was afterwards taken without reserve : he frequently amused himself with washing in the bowl which was set for the dog to drink out of ; and, while he was thus employed, he shewed marks of the greatest indignation if either of his companions presumed to interrupt him. He died in the asylum he had thus chosen, being choaked with something he had picked up from the floor.

POACHER. A name given to those nocturnal depredators, by whom the game is so shamefully destroyed, in opposition to all law and in defiance of order. A poacher frequently exhibits external marks or characteristics of his profession : for instance, the suspicious leer of his hollow and sunken eye, his pallid cheek, his wide, copious jacket—in fact, his *tout ensemble* is impressively at variance with that which is exhibited by any other class of the human species. He contracts habits of idleness to such a degree, that he can scarcely ever persuade himself to work even at that period of the year when there is no longer an illicit market open for the fruits of his nocturnal depredation. As the month of September draws near, he puts his tackle in order—he prepares his destructive net, and watches with unwearied perseverance the jucking of partridges. During the season of his culpable exertion, when the rest of the world is lulled in repose, he is busied in his nefarious pursuits amidst the noxious dews of evening, amongst which he has frequently to secrete himself till he is half perished, anxiously waiting for the favourable moment, or thus eluding the inquisitive search of the gamekeeper. He retires to feverish and uncertain repose, when the more honest part of the community rise from their peaceful couches to commence their diurnal

## P O A C H E R

labour. He rises at mid-day scarcely refreshed, and seeks to renew, in the fumes of strong drink, the exhaustion which nature has experienced from the noxious prowling of the preceding night:—he thus prepares himself for a continuance of depredation. His habitation seems to take its tone from its wretched master—it wears a different appearance from those which surround it; his wife and children are clothed in rags; while he, even if unmolested, dies prematurely of an accumulation of disease, the natural result of his pernicious habits!

“It is, perhaps, among that description of persons well known by the name of *poachers* (observes a writer) that the greater number of those are trained to rapine, who infest every rural neighbourhood with their petty thefts, and whose dexterity almost bids defiance to precaution. Accustomed in the ensnaring of game, to the secrecy of fraud, and committing their depredations amidst the silence of night, those horrors, and that consequent dread, which frequently deter from the commission of great offences, gradually lose their effects. Solitude and darkness, which have heretofore to appal the human mind in its first deviations into guilt, are divested of their terror in those pilfering pursuits; and the consequence is sufficiently well known to all, who, in the capacity of magistrates, are called to sit in judgment on the delinquency of public offenders. It is to this initiation they ascribe their subsequent enormities.

When guilt, however venial, becomes, by repetition, familiar to the mind, it is not in the power of the ignorant and uneducated to restrain its excesses; they cannot arrest their career of iniquity; they cannot chalk out the line of wrong beyond which they will not pass. Confining their first nocturnal excursions to the snaring of hares, and netting of partridges, whenever they have a less booty than usual, they are tempted to compensate the deficiency by petty plunder of some kind; and the log pile, the stack, the fold, the hen roost, all in turn pay tribute to the prowling vagabond, who fills as he can that void in his capacious bag, which has been left by his want of success as a poacher.

The great evil is, that a culprit of this class, feeling no compunction in the early stage of his guilt, proceeds carelessly to a state of the most complete degeneracy. Game is a species of property of which he has so indistinct a conception, that he scarcely thinks he has committed a moral injustice in the various stratagems by which he has contrived to obtain it; he sees not that the claim of another is better than his; he knows not whence that absolute legal right in another to that which he has taken, is derived; his companions, to whom he recounts his manœuvres, are more likely to applaud his cunning than to reprove his crime. Thus, the remorse of conscience being but slight and feeble in the outset, the wretch is encouraged by degrees to trample on the laws with greater boldness, and at length suffers as a felon!

That laws should be made to prevent the man whose family depends entirely on his labour for support, from quitting his spade, or his plough, to range the woods for a precarious subsistence, by the

## P O A C H E R

destruction of animals, must be conceded by all who contribute to the fund which is exacted for the support of the indigent in this country ; and the writer who paints in his closet the hardship of the husbandman, in being restrained from capturing what is called game, would, in his parlour, be amongst the foremost to grumble at the demand of an increased rate, occasioned by the families of half a dozen poachers coming suddenly upon the parish purse, to which he paid.

Of poachers resorting to the most desperate measures, and of even committing murder, the instances are too numerous and too notorious to need a further detail in this place. Of the extent of a poacher's labours in his vocation, a display was made in 1793, upon searching the house of a farmer in Yorkshire, when a great quantity of snares and other implements were found, and *fifteen hundred hare skins*, to all appearance killed that season ; and, to crown the whole, the culprit was constable of the parish, and *openly* very alert against offenders of his own class.

In Barnstaple, Devonshire, in 1795, died Mrs. Barbara Snellgrove, at the advanced age of 96 : and, until upwards of 94, distinguished as the most noted and most accomplished female poacher that had ever figured in this species of depredation. The skill of *Granny Bab* (the name she was known by) in taking all kinds of game, was never surpassed. She frequently boasted of selling fish to gentlemen taken out of their own ponds, and game from their own manors. Her coffin and shroud she kept in her apartments twenty years previous to her decease.

The following is a striking proof of the determined perseverance and resolution with which poachers pursue their avocation :—During a snow, in 1804, a noted poacher was shooting at a covey of partridges on the manors of Worthen and Brockton : the gun burst and terribly shattered his left hand. On his way home, he was met by a neighbour, who, observing his hand bleeding freely, inquired the cause ; when the other replied, “ the gun burst, and has blown off two of my fingers ; but never mind that, mun, I ha’ got the birds ! ”

The following verses were written on a “ man who had once been a farmer of very respectable character ; at length, however, sloth, drunkenness, and bad company, brought on his ruin, and he commenced poaching for a subsistence.” They originally appeared in the second volume of that interesting work, the *Annals of Sporting* :—

In yon wood, where the oak trees their branches are flinging  
Across the wild path, to the woodman scarce known,  
Over which, from its side, the dark fern is springing,  
And woodbine and briars together are clinging,  
Entangling the track, stands a cottage alone,  
Half hid by the brambles that o’er it have grown,  
And the ivy that loves o’er the ruin to roam ;  
While the windows all broken, a garden neglected,  
That ’mid the rank weeds can be scarcely detected,  
Of sloth and of poverty picture the home :—  
And such is the picture of Will Hubert’s dwelling,  
Once of fair honest fame till by vice led astray,  
And drunkenness each bitter feeling expelling,  
To merited poverty left him a prey ;

## P O A C H E R

And scorned by his friends of his honest name,  
That name which alone can true happiness give,  
For shame and dishonour he bartered fair fame,  
The lost lonely life of a *poacher* to live.

In the twilight hour, when the rear mouse is flitting,  
And from some gray ruin the owl's heard to shriek,  
His low ruined hut oft is Hubert seen quitting,  
With net and with setter the meadows to seek ;  
When, lo ! on some wide spreading stubble his setter,  
Low creeping along, shews the covey is nigh ;  
Whilst Hubert approaches, all cautious, the better  
To mark their position, and see how they lie ;  
Then one end of his net in the earth firmly staking,  
As near to the game, unwaked, he can get,  
With the other around them, a wide circuit making,  
O'er the whole of the covey he draws the light net.  
Then, laden with spoil, to his cottage returning,  
He lays him to rest till the dawn of the day,  
And hastes to the road with the first break of morning,  
To meet the stage-coach and deliver his prey  
To his crony, the guard, with the old whisper'd warning —  
“ They're a sackful of birds—stow 'em out of the way.”

Oft to the warren, on the moor,  
When bright o'er all the moon-beam shin'd,  
His ferrets and his nets he bore,  
Whilst his dark lurcher lurked behind,  
And 'neath the shadow of the wall,  
One moment would he pause to see,  
In circling round the rabbits play,  
Light frisking in the silver ray  
In rapid movements light and free ;  
Then gave the signal—at the call  
At each wide spring and rapid bound  
A bleeding victim stain'd the ground,  
Till deep in earth the fearful race  
Seek shelter from their sullen foe  
In vain, for now the ferrets trace  
Each mazy burrow far below,  
And urge them forth in wild affright ;  
While Hubert stands, with ready net,  
Carefully o'er each entrance set,  
To intercept them in their flight.

Far in some marshy woodland glade,  
Where slow the sluggish waters ooze  
Across the track by woodcocks made,  
His well-limed twigs he often laid ;  
Or spread around the running nooze ;  
Or to some fenny mere he'd go,  
Where waving reeds and rushes grow,  
Where teal and wigeon love to sport,  
And duck and mallard oft resort,  
Where wild-geese wet their pinions grey,  
And stately herons love to stray ;  
There, o'er the shallow water's bed,  
His baited hooks at eve he'd spread,  
And leave them till the coming day,  
When flutt'ring o'er the ruffled tide,  
The teal and wigeon strive in vain ;

## P O A C H E R

And e'en the heron's crested pride  
By the frail slender line is ta'en.

Various too, the snares he'd spread  
Where pheasants haunt the green wood shade :  
Along their paths he'd lime-twigs lay,  
Or spread the hair nooze in their way ;  
Or barley, oats, or wheat he'd use,  
Steep'd in the Indian berry's juice,  
Which, by the heedless birds devour'd,  
Makes them fall senseless and o'erpowered,  
At once a rich and easy prey :

Or, when at eve, amid the trees,  
The pheasants to their roost were gone,  
And hush'd and still was every breeze,  
Oft would he seek the wood alone ;  
And 'neath some tree he'd take his stand,  
A sulphur match light in his hand,  
When noxious vapours upwards thrown,  
Thro' all the leaves and branches crept,  
Stifling the pheasants as they slept.

Or in the dusk his snares he'd lay  
Within the entrance of some break,  
There to remain till break of day,  
In hopes the timid hare to take :  
Nor vain his hopes—for seldom he,  
When he revisited his snares,  
Scarce ever failed at morn to see  
A hare reward his evening cares.

---

Such is the life that Hubert spends,  
Each night to lawless practice lent,  
Each day in low-liv'd pleasure spent  
In some near pot house, with his friends ;  
Not like the friends which once he knew,  
When pass'd his days in honest toil ;  
But thieves and rogues, a drunken crew,  
Share in the product of his spoil ;  
While filthy jest, or obscure song,  
All day the boisterous mirth prolong.

We have another picture upon the same subject, from the pen of the celebrated Sir Walter Scott, the expression of which is very forcible, and the composition altogether very poetical and highly interesting. It offers a different view of the same subject—more interesting, more impressive, and much more poetical.

Seek we yon glade, where the proud oak o'ertops  
Wide waving seas of birch and hazel copse,  
Leaving between deserted isles of land,  
Where stunted heath is patched with ruddy sand ;  
And lonely on the waste the yew is seen,  
Or straggling hollies spread a brighter green.  
Here, little worn, and winding dark and steep,  
Our scarce-mark'd path descends yon dingle deep :  
Follow—but heedful—cautious of a trip—  
In earthly mire philosophy may slip.  
Step slow and wary o'er the swampy stream,  
Till, guided by the charcoal's smothering steam,

## P O A C H I E R

We reach the frail, yet barricaded, door  
 Of hovel form'd for poorest of the poor.  
 No hearth the fire, no vent the smoke receives,  
 The walls are wattles, and the covering leaves;  
 For if such hut, our forest statutes say,  
 Rise in the progress of one night and day,  
 ('Tho' plac'd where still the Conqueror's hests o'erawe,  
 And his son's stirrup shines the badge of law\*)  
 The builder claims the unenviable boon,  
 To tenant dwelling, framed as slight and soon  
 As wigwam wild, that shrouds the native frore  
 On the bleak coast of frost-barr'd Labradore.

Approach, and thro' the unlatticed window peep—  
 Nay, shrink not back, the inmate is asleep,  
 Sunk mid yon sordid blankets, till the sun  
 Stoop to the west, the plunderer's toils are done.  
 Loaded and primed, and prompt for desperate hand,  
 Rifle and fowling-piece beside him stand;  
 While round the hut are in disorder laid  
 The tools and booty of his lawless trade;  
 For force or fraud, resistance or escape,  
 The crow, the saw, the bludgeon, and the crape.  
 His pilfer'd powder in yon nook he hoards,  
 And the filch'd lead the church's roof affords—  
 (Hence shall the rector's congregation fret,  
 That while his sermon's dry, his walls are wet.)  
 The fish-spear barbed, the sweeping net, are there,  
 Doe-hides and pheasant plumes, and skins of hare,  
 Cordage for toils, and wiring for the snare.  
 Barter'd for game from chase or warren won,  
 Yon cask holds *moonlight*†, run when moon was none;  
 And late snatch'd spoils lie stow'd in hutch apart,  
 To wait th' associate higgler's evening cart.  
 Look on his pallet foul, and mark his rest:  
 What scenes perturb'd are acting in his breast!  
 His sable brow is wet and wrung with pain,  
 And his dilated nostril toils in vain;  
 For short and scant the breath each effort draws,  
 And, 'twixt each effort, nature claims a pause.  
 Beyond the loose and sable neckcloth stretch'd,  
 His sinewy throat seems by convulsions twitch'd,  
 While the tongue falters, as to utterance loath,  
 Sounds of dire import—watch-word, threat, and oath.  
 Though stupified by toil and drugged with gin,  
 The body sleeps, the restless guest within  
 Now plies on wood and wold his lawless trade,  
 Now in the fangs of justice wakes dismay'd.—

“Was that wild start of terror and despair,  
 Those bursting eyeballs and that wilder'd air,  
 Signs of compunction for a murdered hare?  
 Do the locks bristle and the eyebrows arch  
 For grouse or partridge massacred in March?”

No, scoffer, no! Attend, and mark with awe,  
 There is no wicket in the gate of law!  
 He that would e'er so slightly set ajar  
 That awful portal must undo the bar;

---

\* Such is the law in the New Forest, Hampshire, tending greatly to increase the various settlements of thieves, smugglers, and deer stealers, who infest it. In the Forest Courts, the presiding judge wears, as a badge of office, an antique stirrup, said to have been that of William Rufus.

† A cant term for smuggled spirits.

Tempting occasion, habit, passion, pride,  
Will join to storm the breach, and force the barrier wide.

That ruffian, whom true men avoid and dread,  
Whom bruisers, poachers, smugglers, call Black Ned,  
Was Edward Mansell once;—the lightest heart  
That ever play'd on holiday his part!  
The leader he in every Christmas game,  
The harvest feast grew blither when he came,  
And liveliest on the chords the bow did glance  
When Edward nam'd the tune and led the dance.  
Kind was his heart, his passions quick and strong,  
Hearty his laugh, and jovial was his song;  
And if he lov'd a gun, his father swore  
“ 'Twas but a trick of youth—would soon be o'er,  
Himself had done the same some thirty years before.”

But he, whose humours spurn law's awful yoke,  
Must herd with those by whom law's bonds are broke.  
The common dread of justice soon allies  
The clown, who robs the warren or excise,  
With sterner felons, train'd to act more dread  
Even with the wretch by whom his fellow bled.  
Then—as in plagues the foul contagions pass,  
Leavening and festering the corrupted mass—  
Guilt leagues with guilt, which mutual motives draw,  
Their hope impunity, their fear the law;  
Their foes, their friends, their rendezvous, the same  
Till the revenue baulk'd, or pilfer'd game,  
Flush the young culprit, and example leads  
To darker villainy, and direr deeds.

Wild howl'd the wind the forest glades along,  
And oft the owl renew'd her dismal song;  
Around the spot where erst he felt the wound,  
Red William's spectre walk'd his midnight round.  
When o'er the swamp he cast his blighting look,  
From the green marshes of the stagnant brook  
The bittern's sullen shout the sedges shook!  
The waning moon, with storm presaging gleam,  
Now gave and now withheld her doubtful beam;  
The old oak stoop'd his arms, then flung them high,  
Bellowing and groaning, to the troubled sky—  
'Twas then that, couch'd amid the brushwood sere  
In Malwood Walk young Mansell watch'd the deer:  
The fattest buck receiv'd his deadly shot—  
The watchful keeper heard and sought the spot.  
Stout were their hearts, and stubborn was the strife,  
O'erpower'd at length, the outlaw drew his knife!  
Next morn a corpse was found upon the fell—  
The rest his waking agony may tell!

**POCHARD, THE.** This species, like the pintail, and some others, is common both to the old and new continent. With us it frequents the fens, as well as the coasts and tide rivers; in which last it is taken sometimes extremely fat in the severest weather. It is not ascertained whether they breed in England; but in France one has been shot in the month of July. Their food is small fish and shells: they are found south as far as

Egypt, about Cairo, and in Carolina, during the winter. They have a hissing voice; their flight is more rapid than that of the wild duck, and the noise made by their wings is quite different; the flocks observe no particular shape in flying, as the duck, in triangles, but form a close body.

The pochard is about the size of a wigeon, weighs one pound twelve ounces; its length is nineteen inches; breadth,

two feet and a half; the bill is broader than the wigeon's, of a deep lead-colour, with a black tip; irides, orange; the head and neck deep chesnut, with a small triangular spot of white under the centre of the lower mandible; the lower part of the neck and breast, and upper part of the back, dusky black; scapulars and wing coverts nearest the body of a greyish white, elegantly marked with narrow lines of black: the exterior wing coverts and quills, dusky brown; secondary quill feathers regularly edged with a stripe of white; the belly ash-coloured and brown; vent feathers, and coverts of tail, black; the tail consists of twelve short feathers, of a deep grey; the legs lead-coloured. The female has the head of a pale reddish brown; the breast is rather of a deeper colour; wing coverts and belly, cinereous; the back marked like that of the male.

These birds are eagerly bought by the London poulterers, under the name of dun birds, as they are deemed excellent

eating: the greater part of what appear in the markets are caught in decoys.

POINT. A horse standing in his stall, or elsewhere, with one fore-leg at some distance before the other, is always concluded to have sustained some injury either in the shoulder, or in the ligamentary junction of the coffin and coronary bones, concealed in the box (or cavity) of the hoof. This is in a considerable degree to be relied on; but there are many instances in which a horse accustoms himself to awkward positions, and they become habitual: some stand with either the near or the off fore-leg eternally before the other, and are as perfectly sound as any horses in the kingdom.

POINT. The position of a pointer when standing steadily at game. When the sportsman perceives this position in one of his dogs, he generally uses the exclamation *Toho!* in order to draw the attention of the other dogs, and render the first steady to the point.

POINTER. The dog which is distinguished by the appellation of the pointer is of foreign origin; and is known not only in Spain, but in Portugal, and also in France, and is indeed to be met with in almost all parts of the continent, as well as in Great Britain and Ireland; with some slight difference, however, of form.

Those pointers direct from Spain (which is supposed to be the original country of the pointer, and thence frequently called the Spanish pointer) which have fallen under the observation of the writer, have been heavy and clumsily formed; those from Portugal are somewhat lighter; while the French breed is remarkable for a wide furrow which runs between the nostrils, and which gives to the animal's countenance a very grotesque appearance. They all, however, exhibit a very different character and form to the setter: they are thick and heavy creatures, with large chubby heads, long pendant ears, and covered with short smooth hair; nor do they always possess that generosity of disposition which is so distinguishing a trait in the character of the setter: on the contrary, they are often ill-tempered and snappish; and in fact are good for little in this country till they have been crossed with the more generous blood of these islands; and a judicious cross of this kind produces the best dogs in the world for the purpose of grouse and partridge shooting.

Yet the conjunction of the setter and the pointer is by no means advisable, since the production generally unites the worst qualities of the two, without any of those requisites perhaps for which the two breeds are most highly prized. Dogs thus produced, are, for the most part, headstrong, turbulent, require excessive correction, and are rarely brought to that steadiness which marks the distinct breeds. It is true, sometimes a first rate dog is produced between a setter and a pointer; but it rarely happens: the cross at best is never to be depended on; and for one good dog, thus obtained, there will be found

[illegible]

## P O I N T E R.

twenty very indifferent or bad ones on an average; while not the least dependance can be placed on the offspring of the very best dogs thus propagated. Excellent dogs have been produced by the fox-hound and the Spaniard; and in all probability the fox-hound had much of the talbot blood; nor have we any hesitation in supposing that excellent pointers might be bred from the talbot and the Spaniard; but since the former is nearly extinct, and as all hounds have been produced from him, and still retain more or less of his blood, the nearer we can approach him the better: therefore, the deep-flewed hound is to be preferred; the kibble, and even lighter kinds of hounds, may answer the purpose; but what is thus gained in speed is not a sufficient compensation for unsteadiness and inferiority of nose. The Spaniard, however, from having been judiciously crossed, has arrived at a degree of perfection so as to leave little to be desired on this head: and excellent pointers are to be met with in most parts of England. They differ from the setter, inasmuch, as when they have approached sufficiently near the game, they stand erect; whereas the true bred setter will either sit upon his haunches or lie close to the ground—generally the latter. It may be also very justly remarked that though a particular strain of either the pointer or setter may have arrived at a great degree of perfection, yet, if continued on the same strain for a length of time, it will degenerate; in order, therefore, to prevent that dwindling or falling off which would inevitably take place, recourse must occasionally be had to other strains; that is, to dogs of the same kind, but bred in different parts of the kingdom, taking care to choose animals of undoubted merit from which to breed; and in order to avoid the possibility of being misunderstood, it will be necessary to observe, that, in thus giving directions for preserving the requisite qualities in perfection, we do not mean in this case that recourse should be had to the talbot, fox-hound, or any other kind of dog used for a distinct purpose, but merely to procure a pointer (either sire or dam) from a distant part of the country, if pointers are the object; and the same in respect to setters.

Pointers often suffer much from sore feet; considerable difference however, will be found amongst them in regard to their feet. White footed dogs perhaps will generally be found more tender in this respect than those whose feet are of a dark colour. Black, brown, or any dark coloured pointers have generally better feet than light coloured dogs; though the latter, if their legs are brown or dark coloured towards the feet, are unobjectionable. A small, narrow-toed, hard foot is a great object to attain, as dogs thus furnished, run well, and are not liable to be foot-sore; dogs, however, with thin, wide-spread, large-balled feet, very soon become foot-sore, cannot endure much fatigue, and are, consequently, scarcely worth keeping.—See the article SHOOTING.

The most remarkable pointer ever known was the celebrated dog, Dash, the property of the late Colonel Thornton. He was produced by a cross of the fox-hound with a high bred pointer bitch; he was remarkable for his style of ranging upon the moors, as well as his superior method of finding; and which, when hunting in inclosures for

partridges, shewed an instinct or sagacity almost incredible, by constantly going up to the birds without any previous quartering of the ground, added to his steadiness in backing other dogs, rendered him, it is supposed, the best pointer which was ever produced. Dash was sold to the late Sir Richard Symons for one hundred and sixty pounds worth of Champaign and Burgundy, which had been bought at the French Ambassador's sale, a hog-head of claret, an elegant gun, and a pointer; with a stipulation that, if any accident befel the dog that might render him unfit to hunt, he was to be returned to the Colonel at the price of fifty guineas. The dog had the misfortune to break his leg, and was sent to Colonel Thornton, who paid the fifty guineas, according to agreement, and he was afterwards kept as a stallion, with, however, little success.

There are many good pointers in various parts of England; and particularly in Yorkshire. In the Highlands of Scotland, the pointers are of a very inferior description, at least those belonging to the natives.

The perfection of the pointer, like that of the hound, is a most desirable object: if the pointer be produced with a handsome form, plenty of bone, good feet, of the middle size; if, in fact, he be produced with a form and figure calculated for motion and endurance, with as large a head as possible; the sportsman will have every reason to be satisfied—in such cases, he approaches as near to perfection as possible.

#### POISON, REMEDY FOR DOGS THAT HAVE TAKEN. See p. 225.

POISON. In the last sixteen years of my practice (says Fearon) I have made various experiments on the effects of the different kinds of what is called poison. From the benefit I have received in such trials, I have been able to learn, that what is termed poisonous substances, have proved to be the most salutary remedies of the *materia medica*; and that their injuries to the system proceed from their having been improperly administered. I have tried very extensively all the substances that are reputed poisonous; as arsenic, corrosive sublimate, terra pouderasa, butter of antimony, opium, blue and white vitriol, hemlock (night shade, or aconite), digitalis or fox glove, nux vomica, &c. &c.

At different times I have given every one of these to horses with the greatest success, in many infectious and inveterate disorders, such as the mange, farcy, the glanders, and other chronic disorders of difficult management.

The mischief arising from them is always in consequence of their improper administration, by giving too large doses at once, either by mistake or ignorance, or with the intent of destroying life.

When they have been thus imprudently or maliciously administered, it is certainly necessary to know what method can be taken to prevent the mischief that might ensue. But when this is the case, it is very often extremely difficult to succeed, nature having denied to the horse the salutary process of vomiting.

Poisons are of various kinds; and, before any attempt is made to relieve, we ought to ascertain, if possible, what kind of poison the animal has taken; without this, little success is to be expected from any thing we can administer.

When arsenic, or corrosive sublimate, has been given, if the accident is discovered in time, the poison may be rendered harmless, by drenching the animal with water in which a quantity of alkali (potass, soda, or salt of tartar), has been dissolved, taking care not to make the solution much sharper than a man can bear in his mouth. It may be made by dissolving an ounce of salt of tartar in eight ounces of water; the quantity to be given, to be regulated by the effects produced by the sublimate; from a pint to a pint and a half, however, may be given at once, and continued till the danger is over. The same treatment may be attempted when arsenic has been given,

with the same appearance of success. In some instances oil, given in a large quantity, from a pint to a quart, has succeeded to eradicate the poisonous quality of arsenic and corrosive sublimate; and indeed it will be found very beneficial after the administration of the above medicines. Opium, and all the vegetable poisonous substances above mentioned, destroy life by a different effect than that of the mineral corrosive, for which oil, or a mucilaginous substance, is a real specific, as the effects of those poisons seem to be to kill by acting entirely on the nerves of the stomach. It is necessary to remind the reader that we consider poisons, with a view of preventing their fatal effects, when accidentally taken in too large quantities only. As to those poisons, which produce their effects by admission into the blood, such as the bite of a mad dog, viper, &c. we refer to the article DOG DISEASES.

#### POISONING & ALLURING FISH.

Walton relates a circumstance of his fishing with Oliver Henely, who usually took three or four worms from his bag, and put them into a small box, where he let them continue half an hour or more previous to his baiting his hook with them. To the question, why he did this? his answer was, "he only picked out the best to be in readiness against his hook's wanting to be new baited:" but, continues Walton, he has been observed, both by myself and others, to catch more fish, especially salmons, than I or any other person that ever fished with him could do; and it was lately told me by one of his most intimate friends, that the box in which the worms were put was anointed with a drop or two of the oil of ivy berries, and that by the worms remaining inclosed, they had incorporated a kind of smell, that to the fish was irresistibly attractive. Walton acknowledges, that in his younger days he tried several oils and devices to induce the fish to bite, but without finding any advantage; and yet he adds, that he has seen men fishing with the same kind of worms and tackle, that have taken five, and sometimes ten, fish to his one. Without presuming to assert that the authority of Walton leans to either side of the question, or to ridicule what some anglers have possibly a reliance upon, a variety of ancient recipes, for the allurement of fish (perhaps first imparted as invaluable secrets,) will be recited, to be adopted or rejected, as may suit the different tempers of modern artists. Some of these excellent receipts, it

must however be remarked, are whimsical enough; such, for instance, as a paste made of "mulberry juice, hedge-hog's fat, oil of water lilies, and a few drops of oil of penny-royal." Some invention was at least employed to select these ingredients; many of the following are equally uncouth: but the sceptic may either indignantly turn over the page, or indulge in the mirth which, to an unbeliever, its perusal may excite. The admirers of these potent spells however insist, that baits to catch fish must have four properties: they must smell well, and that makes fish come from remote places; for this, anniseed, juice of panan, cumin, which is best of all, is to be employed. Secondly, they must taste well, that thereby they may be deceived; for which use blood, especially hog's blood, and wheat bread. Thirdly, the baits must fume to the head, to make them drunk; as aqua-vitæ, lees of wine. Lastly, they must render them senseless: such as marigold flowers, for these will make great fish astonished in one hour's time; so will lime, nux-vomica, but nothing better than *coccus indicus*.

Fish may be collected into any part of a river or piece of water, by throwing in goat's, sheep's, and bullock's blood, which is found among the entrails of the fresh killed animals, pounded well together with thyme, marjoram, origanum, flour, garlic, wine lees, and suet, and the whole made into pills.

For a standing water, heart-wort and slack lime made into a paste, will fix the fish so as to be taken at pleasure.

Fresh horse-dung put into a net, and thrown into the water, will entice the fish about it.

Quicksilver let down to the bottom of the water, in a thick glass phial, on a moonlight night, will evince its power, to a quick-sighted observer, of drawing the fish together.

Barley boiled until it bursts, then re-boiled with liquorice, a little mummy and honey beat in a mortar until stiff as paste, and thrown into the water, will induce the fish to come where it is cast.

Goat's blood, barley meal, and the lungs of a goat boiled and pounded fine, and mixed with lees of sweet wine; the whole made into pills, and thrown into ponds or pits, will soon render the fish intoxicated, which the person probably was who bestowed his labour to form the composition.

Extract the juice of dragon-wort, rub the hands with it, and hold them in the

water about five or six in the morning; and it is the performer's own fault, if he has not fish for dinner.

House leek juice, with nettles and cinquefoil, chopped small, distributed in quantities in the water, and the hands previously rubbed with it, induce the fish to come to the person, that he may take his choice.

Coculus indicus, or fisher's berries, pounded in a mortar with water into a paste, made up into pills, and thrown into any undisturbed part of a pond or river, will so intoxicate every fish that swallows any of them, that they will float on the surface, and may be taken out by the hand or landing-net. To the coculus indicus, some add cumin, old cheese, wine lees, and wheat flower. It is to be observed, for the benefit of those who do not wish to be poisoned, that those berries, are of a deleterious nature; and it depends upon the size of the fishes, and of the quantity of the paste they pick up, whether it kills or only intoxicates them. It is said that those which have eaten sparingly, by being immediately put into fresh water, will recover, and (if meant for the table) may, when well gutted and cleaned, be eaten with safety; but it is submitted, that even an alderman would pause, before he indulged his appetite with fish, that might call for the aid of powerful antidotes, before even the cloth was removed. If the dish, when dressed, could be made to fall to the lot of the poacher only, who employs this dangerous mode of obtaining fish, the practice, from motives of personal safety, would soon cease\*.

Heron's fat, mummy, galbanum, two grains; musk, one; mixt in an earthen porringer over a gentle fire, with two ounces of aqua vitæ, and stirred until thick, then kept in a leaden vessel, will preclude all use of a bait; for, by rubbing the hook, ends of the line, or cork, the fish may be taken out with the hand, or the practitioner may fasten them on the

hook himself, if he prefers the pleasure of landing them scientifically.

Heron's flesh, with some musk, amber, and civet, put into a bottle, close covered with wax; the bottle to be placed in a kettle full of water, and boil it until the said flesh is converted into oil; and this rubbed on the line insures the coming of the fish to be taken.

Heron's bowels cut in pieces, and put into a phial, and buried in horse dung, will turn to oil in fifteen days; an ounce of assafoetida is then to be mixed, when it will be the consistence of honey: anoint line, rod, or bait, (it does not much signify which) and it will do wonders.

Oil of ivy berries has been already spoken of, and what it can do in scenting worms for taking fish. Any one may procure gum ivy, which is said to be still more powerful, by driving some great nails into ivy stalks at Michaelmas; and having wriggled the nails until loosened, they are to remain, and the gum will flow from the wounded parts, which the operator may collect monthly, or oftener, if convenient.

Gum ivy, two ounces dissolved in a gill of spring water, mixt together with the like quantity of oil of sweet almonds; the worms, well scoured, intended for the day's use, are to be put into linen thrums (or the ends of the warp, when the piece is finished) well washed in spring water and squeezed; the thrums are then to be wetted in this composition, and with the worms put into a linen bag, from whence they are to be used.

Assafoetida, three drachms; spikenard of Spain, one; put into a pint of spring water; place it in the ground in the shade fourteen days; drain the solution through a linen cloth, and add to the liquor one drachm of spermaceti, and keep it close; put the worms (well scoured) meant to be used, upon a pewter plate, and pour some of the water over them, and then return them into the moss.

Put camphor in the moss, where the worms are for the day's fishing.

For a trout in muddy water, and for gudgeons in clear, anoint eight inches of the line next the hook with the following:—Assafoetida, three drachms; camphor and Venice turpentine, of each one; pounded together in a mortar, with some drops of the chemical oil of lavender or spike.

Sea-gulls' fat and eringo juice, mixed together, are asserted to have great at-

---

\* In 1788 an accident of this kind, which terminated fatally, happened in Lancashire. Two young men having caught a large quantity of trout, by mixing lime with the water in a small brook, ate heartily of the trout at dinner the next day: they were seized at midnight with violent pains in the intestines; and though medical assistance was immediately procured, they expired before noon in the greatest agonies.

traction as an unguent; and oil of amber, rosemary, and myrrh, equal portions of each, mixed with the worms or in paste, are said to make the bait so tempting, that no fish in his senses can resist it: worms also, killed by putting them into a phial of oil of camomile, prove an equally irresistible morsel.

To be certain of a net's doing execution, beat nettles with joubarbe, and a small quantity of cinquefoil grass; to them add wheat boiled in marjoram and thyme water; pound the whole together, and drop it into the net.

Marjoram, marigolds, wheat flower, and rancid butter, pounded together, will allure fish of all kinds to the net. A natural query arises as to the kind of nets, and in what manner these baits are to be retained in them?

*Scented ground bait.* Unpickled samphire bruised, made up in balls with walnut-oil, is pronounced excellent for carp, bream, or tench; also bean flour, with a little honey, wetted with rectified spirits of wine and oil of turpentine, made up in small pellets, and thrown in over night, will keep the fish at the place, where they may be found with all desirable keenness, ready for biting, the next morning.

Juice of camomile, half a spoonful; chemical oil of spike, one drachm: oil of canary by infusion, one drachm and a half; goose grease, two drachms: these are to be dissolved over the fire, and stand until cold, then are to be put into a bottle unstopped for three or four days, then to be corked close, and the bait to be anointed with it; when to this is added three drachms of the spirit of vitriol, it is called (but perhaps not so universally found to be) the infallible bait.

A part of the same fish designed to be angled for, bruised to pieces with fennel and honey, put into clear water, and boiled to an oily consistence as thick as mustard: and the oily liquor strained through a linen cloth, into which not only the worm on the hook, but ten inches of the line, are to be frequently dipped, has great effect, but is very erroneously (it is conceived) stated to be Mr. Walton's prime receipt.

The nostrum that will however answer most profitably to him that tries it, is taking a fat goose or duck, and stuffing him with sage, marjoram, and fresh lavender shred small; together with castor, gum ammoniac, nutmeg, mace, and cloves beat well together in a mortar; the bird is to be roasted and eaten; the dripping

only, when mixed with the oil of a dead man's skull, and oil of earth-worms, (which must be the quintessence of the last ingredient) is to be used as an ointment; it is presumed the roasted animal will receive more bites, than the dripping will be able to acquire with all its additional allurements. But the grand secret is yet to be unfolded, upon which too high a value cannot be attached: cat's, heron's, and man's fat, mummy, and the best assafoetida, of each two drachms; cumin seed finely powdered, two scruples; camphor, galbanum, and Venice turpentine, of each one drachm, and civet two grains; make them up, *sec. artem*, into a thinnish ointment, with the chemical oils of lavender, anniseed, and camomile; keep it in a narrow mouthed, well-glazed gallipot, covered with bladder and leather, and it may be preserved two years. When wanted, put some of it into a taper pewter box, and anoint the line with it about nine or ten inches from the hook; when it is washed off, repeat the unction, and if the fish is so infatuated as to swallow the line first, and the hook and bait afterwards, there certainly will be ample proof of its efficacy.

The idea of charming fish is not peculiar to European practitioners: it is resorted to in various parts of the world. We are told that the Indians at Hudson's Bay, when they bait their hooks in angling, first sew a composition of four, five, or six articles round it by way of charm. The materials are bits of beavers' tails and fat; otters vent and teeth; musk-rats' guts and tails; loons' vents; squirrels' testicles; the curdled milk taken out of the stomach of sucking fawns and calves; human hair, and numberless other articles equally absurd. Every master of a family has a bundle of such trash, which they always carry about with them both in summer and winter; and without some of these articles to put under their bait, few of them could be prevailed upon to put a hook into the water, being fully persuaded that they may as well sit in their tent as angle without such assistance. They have also a notion that fish of the same species, inhabiting different parts of the country, are fond of different things, so that almost every lake and river requires an alteration of the charm. The same rule is observed on broiling the first fruits of a new hook that is used for a new net; and an old hook that has already been successful in catching large fish is esteemed more valuable than a

handful of new ones which have never been tried.

This superstitious method of alluring the fish is not confined to the hook only, but a new net must have the bills and feet of the laughing goose, wavey, gulls, loons, and blackheads, fastened to its head and foot-rope; and at the four corners, the toes and jaws of an otter and jackass; and unless some or all of these be fastened to the net, they will not attempt to put it into the water, firmly believing it would

not catch a single fish. The first fish, of whatever species caught, in a new net are not to be sodden in water, but broiled whole, and the flesh carefully taken from the bones without dislocating one joint; after which the bones are laid on the fire at full length, and burnt. A strict observance of these rules is supposed indispensable for the future success of the new net, and a neglect of them would render it not worth a farthing.

**POLECAT.** This animal, which is very destructive to game, and consequently a great enemy to the sportsman, passes under various names or local appellations. In some parts of this country it is known by the name which appears at the commencement of this article; in others it is called a phillemark, a fitchet, or a founmart. The polecat is larger than the ferret, which it very much resembles in form; there are, however, internal differences which distinctly mark these two animals, and the vulgar report that they will mix or breed together, has, in all probability, no better foundation than fanciful ignorance: the polecat has but fourteen ribs; whereas, the ferret has fifteen; and it also wants one of the breast bones which is found in the ferret. The polecat has a blunter nose than the ferret, and is not quite so slender. It is, for the most part, of a deep chocolate colour; it is white about the mouth; the ears are short, rounded, and tipped with white; a little beyond the corners of the mouth, a stripe begins which runs backward, partly white, and partly yellow: its hair is of two sorts, the long and the furry, and the two kinds are of different colours; the longest is black and the shorter a dull or dirty yellow; which of course causes the *toute ensemble* to assume the chocolate appearance before mentioned: the throat, feet, and tail, are blacker than any other parts; the claws are white underneath and brown above; and its tail is about two inches and a half long. The polecat, like the fox, avoids as much as possible, the human countenance; and, like the fox too, possesses the most undaunted courage: it evinces an insatiable thirst for blood, and is very destructive to young game of all kinds; if it is not openly so to that which is full grown, it is because it is not so easily caught: it will surprise hares on their seats, will seize partridges or pheasants on the nest; and is incredibly destructive in a rabbit warren. Their retreat is generally in banks well sheltered with brambles or underwood, or amongst brakes or woods, or other similar situations. They burrow in the ground, making a tolerably large hole about two feet deep, which may easily be known by any person who has ever noticed the hole of a polecat. In winter they will frequently approach houses or buildings, and will rob the hen roost, the pigeon house, or even the dairy: on these occasions, they contrive to form a retreat either in or under some of the walls, from which they are not easily dislodged; if they are unable to secure an asylum of this sort, they will make their way under the corn stacks of the farmer, and whenever

this happens to be the case, all the rats in the immediate vicinity remove to a greater distance: the polecat is a deadly enemy to the rat, and of this the latter is very well aware; yet it is also conscious of the inability of the polecat to pursue it through its burrows or runs, and therefore removes no further from the presence of its enemy than what may suit its convenience; thus the writer of this article witnessed an instance where a great number of rats were found in a stack of wheat, but all of them in the upper part; for several yards from the ground, not a rat was to be met with, which excited some surprise; but the circumstance was fully explained on reaching the bottom, where it was found an enormous polecat had taken up its abode.

The female brings forth her young in the spring, to the number of from four to six at a time. To "stink like a polecat" is a common observation in some parts; and indeed so impregnated does every part of this animal appear to be with a very offensive fetid matter, that even the fur, which is soft and warm, can scarcely be divested of it:—whenever the polecat happens to be killed, the fetid matter just mentioned issues from the pores of its body in great quantities, forming a very unpleasant effluvium, which is perceptible at some distance, even to the obtuse olfactory organs of a human being.

There are farmers to be met with, who, whenever a polecat approaches their barns or outhouses, afford it every possible protection, on account of its enmity to rats; but as its chief propensities are in direct opposition to the views of the sportsman, so gamekeepers should be careful to destroy it wherever it is to be met with. It may be caught by means of traps, or by terriers. In the midland counties, hunting the polecat by moonlight forms a diversion for school-boys and the younger branches. The polecat leaves its hole when night sets in, and prowls for prey; it is then quested for and chased by terriers, one of which (the best) has a small bell fastened round his neck, in order to give notice to the hunters when the dogs are out of sight, though, when they are in chase, they open of course: the polecat makes directly for its hole, and if it be not killed before it reaches it, the animal is dug out and worried on the spot.

POLL-EVIL (says Feron) is nothing more than a common abscess, situated on the top of the head, running between the ligaments and bones of the neck and head, which, in a very short time, will form many sinuses. There, in consequence of being so deeply seated, matter cannot find vent at the surface by bursting the skin, like a common abscess, but spreads so much under the bones and ligaments of it, as to be shortly highly diseased, before suppuration shews itself externally. And if the matter is allowed to continue its ravages upon those parts, the ligamentum colli itself becomes affected, and the case often rendered incurable. This complicated ulcer and sinuses will

shew how little is to be expected from the frivolous and empirical applications of the generality of common horse doctors, who, not possessing an atom of anatomical knowledge, cannot expect their receipts to be adequate to the task of curing; the consequence is, that in such hands the animal often terminates his sufferings by being sent to the dog kennels. Poll-evil (as it is called) generally proceeds from external injuries, such as a violent blow received on the top of the head, by striking it against the ceiling of a low stable, or by the brutality of man, &c. &c.

*The Treatment* of this disease is extremely easy; if the accident is recent, it

will often give way to one or two applications of a strong blister, and a copious fomentation of warm water twenty-four hours after. By this simple treatment, carie of the bones, and ligaments of the head and neck, will be prevented. But when matter and sinuses are formed, the disease requires more bold and scientific treatment: we must begin by giving a free discharge to the matter or pus at the inferior and lowest part of the abscess in proper time, by opening every hole or sinus by making an incision through the whole extent of the cavity, when it can be done with safety, and then introduce a seton or two on each side of the head, or in the cavities or sinuses themselves, which should be moved every day, and washed with spirits of turpentine, taking care to keep a free and constant discharge, until the bottom of the wound gets sound, if the bones of the head or neck are greatly enlarged, and carious; in this deplorable state, the actual cautery must be introduced to the bottom of every sinus, in order to produce exfoliation of the rotten particles of bones as quickly as possible; which operation is often found necessary to be repeated, in order to keep the orifice open, until all the sinuses are completely filled up, without which no cure can be expected; and, indeed, it is entirely owing to this circumstance, that the cure of the poll-evil is often rendered impracticable.

#### POMERANIAN or WOLF-DOG.

The dog, so called in this country, is but little more than eighteen or twenty inches in height, and is distinguished by his long, thick, and rather upright coat, forming a ruff round the neck, but short and smooth on the head and ears; they are mostly of a pale yellow or cream colour, and lightest on the lower parts. Some are white, some few black, and others, but very rarely, spotted; the head broad

towards the neck, and narrowing to the muzzle; ears short, pointed, and erect; nose and eyes mostly black; the tail large and brushy, invariably curled in a ring upon the back. In England, this animal is better known by the name of fox-dog, and this may originally have proceeded from his bearing some affinity to that animal about the head.

This animal is by nature frivolous, artful, noisy, quarrelsome, cowardly, petulant, and deceitful; snappish and dangerous among children, without one predominant property of perfection to recommend him. This breed of dogs is common in Holland, and the animal has occasionally been introduced as a hieroglyphic by the caricaturist partisans of the House of Orange (in opposition to the pug) to ridicule the patriots in their political disputes. There is this peculiarity in the coat of this dog: his hair, particularly the ruff about his neck, is not formed of hairs calculated to describe the serpentine, or line of beauty, but is simply a semicircle, which, by inclining the same way in large masses, give him a respectable and attractive appearance; and, although they do not manifest so great a degree of fondness and affection for their owners as some others of this species, yet they are not to be readily or easily seduced. The largest of these dogs are used for draught in different countries, particularly by the Kamtschadales, and indeed by most of the nomadick nations. From the name (Pomeranian) it might be supposed that they were originally bred in that country; but this is not the case; they are to be found in almost all the northern regions, where they are used as beasts of burden or draught: while nature, kind to all her creatures, has provided them with an uncommon warm coat, as a protection against the cold and dreary climate which they inhabit.

**POOL SNIPE or REDSHANK.** The pool snipe resides the greater part of the year in the fen and marshy countries, where it is pretty common; and there it breeds and rears its young, laying four whitish eggs, tinged with olive, and marked with irregular black spots, most numerous at the large end. When disturbed, it has nearly the actions of a lapwing, in flying round its nest, which it is said to do in such regular circles, the nest being in the centre, whether the circuits be larger or smaller, insomuch that an attentive observer will find it by this circumstance. The pool snipe is in length twelve inches, in breadth twenty-one, and weighs about six ounces: the bill is two inches long, slender, and like a woodcock's: of a dark

red at the base, and black towards the point: the tongue is sharp and undivided; the upper mandible longer, and sometimes crooked at the very tip: irides reddish hazel; a whitish line passes over and encircles each eye, from the corner of which a dusky brown spot is extended to the beak. The head and hind part of the neck, dusky ash-colour, spotted with brown: back and scapulars glossy olive brown: wing coverts ash-colour, mixed with dusky and brown, and marked with whitish spots: the bastard wing and primary quills are brown; the inner webs of the latter are deeply edged with white freckled with brown, and some of these quills next the secondaries are elegantly marked near their tips with narrow brown lines, pointed and shaped to the form of each feather. Some of the secondaries are similarly barred, others are white: the throat and fore part of the breast are marked with short dusky spots; the under parts from the breast, and the lower parts of the back and rump, white, marked with minute dusky spots: tail coverts and tail crossed with narrow bars of black, twelve or thirteen on each feather: legs orange red, and measure, from the end of the toes to the upper bare part of the thigh, five inches and a half: claws black. In some birds, both the rump and belly are of a pure white. The pool snipe is common in many parts of Europe, as high as Finland; is likewise found in Siberia, and is indigenous also to the continent of America.

**POST MATCH.** A term in racing, where it is only necessary to insert the age of the horses in the articles, and to run any horse of that age, without declaring what horse, till he appears at the post.

**POT-EIGHT-O'S.** A chesnut horse, foaled in 1773, bred by the Earl of Abingdon, and sold to Lord Grosvenor.

Pot8o's was got by Eclipse, out of Sportsmistress.

At Newmarket first spring meeting, 1776, Pot8o's, 8st. 1lb. won a sweepstakes of 100gs. each, Bunbury's Mile, beating the Duke of Northumberland's filly, by Match'em, 7st. 13lb.; and Mr. Vernon's br. filly, by Snap, 7st. 13lb.—6 to 4 on Pot8o's.

At Newmarket first spring meeting, 1777, Pot8o's came second to Lord Grosvenor's Yellow Jack, for the claret stakes, by which he was entitled to two hogsheads of claret:—In the same year, he was beat by Grey Robin and Cannibal, also by Mr. Swinfen's ches. colt, Country Squire, by Chrysolite, out of Shark's dam.

At Newmarket first spring meeting, 1778, Pot8o's won the renewed 1200gs. a subscription of 100gs. each, (eight subscribers) 9st. R. C. beating Lord Grosvenor's Grey Robin, and Lord Ossory's Titan:—11 to 5 on Pot8o's. In the second spring meeting, he won the 140gs. for five-years old horses, &c. B. C. beat-

ing Mr. Vernon's Rasselas, and Sir C. Sedley's Fleacatcher:—2 to 1 on Pot8o's. At Ipswich, June 29th, he walked over for a subscription of 25gs. each (seven subscribers), for all ages. At Swaffham, September 23, at 8st. he won 50l. for horses, &c. four-mile heats, beating Sir C. Sedley's Ratcatcher, 5 years old, 8st.; Sir C. Bunbury's Tycho, 4 years old, 7st. 2lb.; and Sir J. Moore's Vestal, 4 years old, 7st. 2lb.—5 to 2 on Pot8o's. At Newmarket second October meeting, he won a subscription of 5gs. each (thirteen subscribers) for four year olds, 7st. 7lb.; five, 8st. 6lb.; and six 8st. 13lb. B. C. beating Lord Foley's Laburnum, 4 years old; Lord Clermont's Il'mio, 4 years old; Mr. Pigott's Humbug, 5 years old; Lord Abingdon's Barbiniola, 4 years old; Mr. Vernon's Rasselas, 5 years old; and Mr. O'Kelly's Freeholder, 6 years old:—2 to 1 against Humbug, 5 to 2 against Pot8o's, 3 to 1 against Laburnum, and 6 to 1 against Il'mio.

At Newmarket first spring meeting, 1779, Pot8o's won 50l. for horses, &c. rising six years old, 8st. 7lb. D. C. beating the Duke of Grafton's Caractacus, and Sir J. Moore's Houghton:—6 to 4 on Pot8o's. On Tuesday, in the second spring meeting, he walked over B. C. for the Clermont cup, for four-years old, &c. On Wednesday, he won the 140gs. for

five-year olds, 8st. 4lb.; six, 8st. 12lb.; and aged, 9st. 2lb. B. C. beating Sir J. Shelly's Comet, 5 years old; the Duke of Grafton's Tickler, 5 years old; and Mr. Vernon's Prince, 6 years old:—even betting on Comet, and 6 to 4 against Pot8o's. On Saturday, he won a subscription of 25gs. each (six subscribers), for four-year olds, 7st. 2lb.; five, 8st. 6lb.; and six, 9st. B. C. beating Mr. Vernon's Pastorella, 5 years old; the Duke of Bolton's Greybeard, 4 years old; and Lord Ossory's Muse, 4 years old:—3 to 1 on Pot8o's. In the first October meeting, he walked over B. C. for the cup, for four-year olds and upwards. On Monday, in the second October meeting, at 8st. 8lb. he won a sweepstakes of 300gs. each, 100gs. ft. B. C. (three subscribers) beating Lord Foley's Laburnum, 5 years old, 7st. 12lb.—even betting. On Wednesday, he won the 140gs. for six-years old and aged horses, &c. 8st. 7lb. B. C. beating Mr. Vernon's Freeholder, aged:—4 to 1 on Pot8o's.

At Newmarket second spring meeting (Monday) 1780, Pot8o's 8st. 2lb.; Lord Derby's Laburnum, 7st. 9lb.; and Mr. Stapleton's Magog, 8st. 7lb. in a sweepstakes of 200gs. each, B. C.—Laburnum walked over, and divided the stakes with Pot8o's. On Tuesday, he walked over B. C. for the Clermont cup. On Wednesday, he won the 140gs. for five-year olds, 8st. 4lb.; and aged, 9st. 2lb. B. C. beating Mr. O'Kelly's King Fergus, 5 years old; and Lord Ossory's Dorimant, aged:—even betting on Pot8o's, 2 to 1 against Dorimant, and 4 to 1 against King Fergus. On Thursday, he won the jockey club purse, for horses, &c. 8st. 7lb. each, B. C. beating Mr. Shafto's Tandem, aged:—3 to 1 on Pot8o's. In the first October meeting, he walked over B. C. for the cup. On Tuesday, in the second October meeting, at 9st. he won a sweepstakes, 200gs. each, h. ft. B. C. beating Lord Derby's Laburnum, 8st.; and Lord G. H. Cavenish's Reputation, 6st. 12lb.—Dictator, 8st. 7lb. paid:—7 to 4 on Laburnum, 5 to 2 against Pot8o's, and 6 to 1 against Reputation. On Wednesday, he walked over B. C. for the 140gs. On Thursday, he won a subscription of 10gs. each, (fifteen subscribers) for horses, &c. aged, 9st. 2lb. D. C. beating Sir C. Davers's Woodpecker, aged; and the Duke of Grafton's Tandem, aged:—6 to 5 on Woodpecker, 2 to 1 against Pot8o's, and 5 to 1 against Tandem.

At Newmarket first spring meeting,

1781, Pot8o's 8st. 7lb. won a sweepstakes of 200gs. each, h. ft. (seven subscribers) B. C. beating Sir C. Davers's Woodpecker, aged, 9st.; Lord Derby's Guildford, 5 years old, 7st. 7lb.; Lord Rockingham's Copperbottom, 4 years old, 7st. 2lb.; and another:—6 to 4 on Pot8o's, 5 to 2 against Woodpecker, and 5 to 1 against Guildford. On Thursday, in the second spring meeting, he walked over B. C. for the jockey club purse. On Saturday, at 9st. 4lb. he won a sweepstakes of 200gs. each, h. ft. B. C. (four subscribers) beating Sir C. Davers's Buccaneer, 5 years old, 8st. 7lb.—7 to 4 on Pot8o's. And in the same meeting, Lord Grosvenor challenged for the whip, and named Pot8o's; but the challenge not being accepted, the whip was delivered to his Lordship. On Tuesday, in the first October meeting, at 9st. he received 230gs. compromise from Lord Clermont's Dictator, 8st. 5lb. B. C. 500gs. h. ft. And on Wednesday, he was named for the 140gs. B. C. against Hollandoise, &c. and received 85gs. to withdraw.

At Newmarket Craven meeting, 1782, Pot8o's won the Craven stakes of 10gs. each, for two-year olds, 6st.; three, 8st.; four, 8st. 9lb.; five, 9st. 11lb.; six, 9st. 5lb.; and aged, 9st. 7lb. from the Ditch to the Turn of the Lands, beating Lord Clermont's Hollandoise, 6 years old; the Duke of Cumberland's Iö, 3 years old; Mr. O'Kelly's Mercury, by Eclipse, 3 years old; Mr. Turner's Quinze, 4 years old; and nine others, which were not placed: amongst whom were Mr. Vernon's Thesaurus, Mr. Walker's Cabal, Mr. Douglas's Crookshanks, the Duke of Grafton's Twilight, Capt. Bertie's John-a-Nokes, and the Duke of Queensberry's Drowsy:—6 to 4 against Pot8o's, 6 to 1 against Hollandoise, and 10 to 1 against Iö. On Monday, in the first spring meeting, he won 50l. for six-year olds, and aged horses, 8st. 7lb.; all others 8st. R. C. beating Sir J. Lade's Laburnum, aged; and Sir J. Shelly's Clandon, 5 years old; 4 to 1 on Pot8o's. On Tuesday, in the second spring meeting, he walked over B. C. for the Clermont cup. On Wednesday, he walked over B. C. for the 140gs. On Thursday, he won the jockey-club purse, 8st. 7lb. each, B. C. beating Sir C. Davers's Buccaneer, 6 years old; and Mr. Walker's Mercury, by Dragon, 6 years old:—5 to 1 on Pot8o's. And on Saturday, at 9st. 4lb. he won a subscription of 25gs. each, (six subscribers) B. C. beating Lord Clermont's Hollandoise, aged, 9st. 4lb.; and Lord Ossory's Alar-

ick, 4 years old, 7st. 2lb.—3 to 1 on Pot8o's.

At Newmarket second spring meeting, 1783, Pot8o's beat Sir J. Lade's Nottingham, 10st. each, B. C. for the whip, and 200gs.—2 to 1 on Pot8o's.

Pot8o's was a stallion at Oxcroft Farm, near Balsham, Cambridgeshire, (the same place as Sweetbriar, Mambrino, Sweetwilliam, Justice, and Protector.) In 1784, he covered at 5gs. and 10s. 6d.; in 1785, 1786, 1787, and 1788, at 10gs. and 10s. 6d.; 1789, &c. twenty mares (besides those of his owner), at 21gs.; in 1796, ten mares (besides those of his owner) at the same price; and afterwards at the Upper Hare Park, near Newmarket, ten mares (besides those of his owner), at 10gs. and 10s. 6d.—He served but few mares besides Lord Grosvenor's.

Pot8o's died in Mr. Golding's stud, the Upper Hare Park, early in November, 1800, aged 27.

**POULTICE.** A soft mass of ingredients, calculated either to soothe an inflamed or ulcerated part by the mere effects of warmth and moisture, or to produce some effect by its stimulus.

*Common Poultice.*

Take of Bran, a quarter of a peck;

Water, a sufficient quantity.

Boil for ten minutes; and then thicken it properly with linseed meal. Add lastly,

Hog's lard, three ounces. Mix.

Or,

Take of Fine pollard, half a peck;

Linseed meal, two pounds and a half;

Boiling water a sufficient quantity. Add lastly,

Hog's lard, two ounces. Mix.

*Fermenting Poultice.*

Boil a quantity of brewer's wort, and stir it into as much oatmeal as will properly thicken it. Add, lastly, a tea-cupful of yeast.

This is well adapted for putrid ulcers or mortified parts.

*Saturnine Poultice.*

Add to the common poultice,

Extract of lead, three drachms or half an ounce.

Mix them well together.

Or,

Take of Acetated ceruse (sugar of lead), one ounce;

Boiling water three quarts. Add Bran and linseed meal, enough to make the whole of a due consistence.

A *suppurative poultice* may be made by stirring a sufficient quantity of common turpentine into some of the common poultice.

An *anodyne poultice* may be prepared in the same way, by adding a sufficient quantity of tincture of opium. In this case, probably the lard had better be omitted, as tending to prevent the free access of the principal ingredients to the skin. Indeed an abundance of grease or oil in poultices is a common error in their composition.

These remedies admit of being varied in a still greater degree by similar means.

**POWDER-FLASK.** A copper flask is preferable to any other. The ingenious Baron de Berenger, a few years since, shewed me a flask of his own invention, so contrived, that in case of ignition while pouring the gunpowder into the barrel, nothing but the mere charge would become ignited. The article was not so complete as the Baron wished, and I have not learned whether he has since perfected his invention.

**PRICKED.** The under surface of the horny covering of the foot is unavoidably exposed to numberless injuries from sharp bodies penetrating its substance, which may happen in various ways, from nails, pointed flints, glass, &c. The shoe being partly torn off, and then stepped upon, may produce it; but the accidental puncture by a nail during shoeing is one of the most frequent causes of these accidents. Injuries of this kind are proportioned in their effects according to the parts punctured, and not entirely to the depth of the wound: a knowledge, therefore, of the anatomical structure of the foot is necessary to enable us to form a prognosis, as well as to establish a proper method of cure. A puncture through the fleshy frog, even to the vascular portion, is not productive usually of such serious consequences, as an apparently more superficial opening made through the centre of the sole, which may penetrate the capsular ligament, and either produce ankylosis or destroy the animal.

Whenever a puncture takes place, of sufficient depth to penetrate to the bony connexions (which may be ascertained by examination with a probe), and synovia escapes, the external opening should be enlarged; but it should be attempted to close the internal opening at once, by the application of the actual cautery, not to the immediate surface of the capsular ligament, but to the skin directly over it.

If, however, this treatment has been neglected, and suppuration has actually taken place, the cautery should be omitted: but the action of the part may yet be attempted to be altered by the application of milder stimulants introduced by means of a brush: as diluted muriate of antimony with oil may be lightly penciled over the outer edges of the capsular orifice; on which may be placed a pledget moistened with tincture of myrrh, or tincture of benjamin, &c.; and any mild digestive may be laid over all as a defence. If the inflammation be considerable, bleed at the toe, and imbed the whole foot in a poultice. A very deep posterior puncture may extend itself into the flexor tendon or its sheath, and is always productive of very great irritation and inflammation. In such case, enlarge the opening, and if the wound be seen immediately after the accident, introduce any very mild stimulant, as the warm tinctures: but if the accident have occurred a day or two, and the inflammation be considerable, bleed at the toe, and place the foot in a saturnine poultice. When suppuration comes on, watch its progress, moderate the inflammation, give a free exit to the matter, and remove any horn that becomes detached. And as the life of these tendinous parts is inconsiderable, at each dressing a little of any of the above warm spirituous applications may be introduced, which will assist the healing; or, if a sloughing of any portion be unavoidable, will tend to assist its separation. A puncture of the sensible sole must be treated in a similar manner, remembering in every instance that caustic, or highly stimulating liquids, should never be introduced, as is often done, except under particular circumstances, which will be noticed. The introduction of tincture of myrrh, tincture of benjamin, or a mild solution of vitriol, &c. at the moment of the accident, is admissable; because it may gently stimulate the part to the adhesive inflammation; and if even suppuration be inevitable, the mildness of such applications cannot aggravate the process.

But the most usual cases of punctures are those which arise from a wrong direction of a nail in shoeing, in which it either presses on or actually wounds the sensible laminæ. This is commonly known to the workman at the time, by a peculiar sensation arising from the different resistance occasioned; or otherwise is detected by the flinching of the horse; when, if the nail be immediately removed,

no ill consequences follow, unless the injury be considerable; and even in this case, were but a little common honesty practised, the serious evils that frequently follow these punctures might be commonly prevented. Were the nail immediately redrawn, the opening enlarged, and a little spirituous balsam of any kind introduced, it would very frequently heal immediately after; and even should it proceed to suppuration, still a depending orifice is made for the evacuation of the matter, and extensive detachment of horn prevented. But when a smith, in shoeing, considers the horse not actually pricked, though he may be conscious that the nail has taken a wrong direction, or is driven too high, he is apt, from laziness, to let it remain; and sometimes, even when he is aware that the nail has penetrated the inner surface of the horn, and wounded the vascular parts, he is often then not sufficiently candid to acknowledge it. The offending nail, therefore, even in such case, is allowed to remain, and, according to the extent of the injury, the inflammation becomes considerable the same night, or perhaps not till two or three days after. In such cases, as suppuration proceeds, the confined matter spreads around, detaching a portion of the fleshy from the horny sole, more or less considerable, and, at last extending upwards, it finds itself an exit by an opening at the coronet. In proceeding this course, the inflammation does not always confine itself to the parts nearest the exterior surface, as the sole and sensible laminæ; but sometimes, when not assisted by an artificial opening, it extends to parts less vascular, and whose action not being of that nature to make them immediately throw off the injury by forcing the matter outwards (as is done by parts more vascular), sinuses form inwards, and the disease then becomes *quittor*. Fortunately, however, the vascular action of the sensitive sole and laminæ being extreme, the matter usually proceeds outwards, and finds an exit at the coronet.

It may therefore, in pursuing this subject, be stated, that at any time when a horse becomes lame within a week after he has been shod, if the origin of it be hid in any obscurity, the shoe should be always first removed, and the foot gently struck all over with taps of the hammer. If the lameness springs from this source, and any part be injured by one nail in particular, at that part the stroke will occasion the horse to flinch. If this fail

to detect the evil, pinch the toe and quarter round with the pincers, which, if the mischief arise from a prick, will readily point out the affected part by the pain felt there; and under this spot matter will have surely formed. Proceed in such case immediately to pare away the horny sole till it be very thin, when, on close inspection, if the paring be done within two or three days from the prick, a dark coloured fluid will ooze from one of the nail holes; but, if a longer period has elapsed, a purulent matter will appear. By a proper opening evacuate this, and then carefully examine the extent of the injury by the probe, as how far the fleshy and horny soles have become separated from each other, for to the same extent must the horn be removed; not, however, taking the whole away the first day, but completing the removal the second. No greasy matter should be applied over the denuded sole, but a pledget of lint, slightly moistened with compound tincture of benjamin (friar's balsam), or tincture of myrrh, may be laid on; and any mild defensive dressing may be applied over this.

When matter has proceeded to evacuate itself by the coronet, exactly a similar plan must be pursued; the original wound below should be traced and opened, so as to give a free exit to the pus. And in all these cases, when the symptomatic fever rages high, bleed, give physic, and treat in every respect as under inflammation. Perfect quiet is absolutely necessary in every instance of puncture; the slightest exercise irritates, and should be avoided. A shoe should be made so as to "*lie off*" the injured parts, and should only be very lightly tacked on with four nails unclenched.—*Blaine*.

**PRICKET.** A male deer of two years old that begins to put forth the head.

**PRICKING.** Tracking a hare by the marks of her feet.

**PROGNOSTICS OF THE WEATHER.** The success of the chase must always depend on the weather; and therefore the following prognostics will be interesting to the sportsman:—

*Clouds.*—When there are two different currents of clouds, especially if the lowest flies fast before the wind, and these appear in hot weather, in the summer, they portend the gathering of a thunderstorm.

When thin whitish clouds fly swiftly in the air under those that are thicker, and when small scattered ones appear in clear weather, *rain*.

When a general cloudiness covers the sky above, with small black fragments of clouds, like smoke, driving underneath, *rain* is not far off, and will probably be lasting.

If a black cloud is seen in the west about sun-setting, and when, at any time, such clouds arise suddenly in that quarter, *rain*.

When clouds are formed like fleeces, dense towards the centre, and very white at the extremities, with a bright and blue sky about them, they are of a frosty coldness, and will soon fall, either in *snow*, *hail*, or hasty showers of *rain*.

Against heavy rain, every cloud rises larger than the former, and all of them appear in an increasing state:—this is perhaps most remarkable on the approach of a thunder storm; after the vapours have been copiously elevated, suspended in the sky by the heat, and are highly charged with the electrical fluid, small pieces of flying clouds augment and assemble together, until, in a short time, they cover the sky: as this collecting of the clouds out of the air, is a certain forerunner of rain, so, when they decay and resolve themselves into air, it is a sure symptom of fair weather.

When clouds are streaming within the canopy, and small ones enlarge themselves; when they are large, and shaped like rocks or towers; when waterish clouds are on the tops of mountains, and small, rugged, livid ones near the sun, especially at its setting, they all prognosticate rain. Clouds, with white summits and livid bases, foretel thunder; and two such clouds, rising on either hand, sudden tempests.

If clouds are seen to breed high in the air, in thin white trains, like locks of wool, they denote that the vapour, as collected, is irregularly spread by contrary winds above; and the consequence will soon be a wind below, and probably rain with it.

Small and white clouds, high and light, and when mountains are free from clouds, high and light, are both symptoms of fine weather.

*Wind.*—Whirlwind, settled fair. Continuing in the north-east three days without rain, *fair* for eight or nine days; going backward, *rain*; when it veers hastily about to several points of the compass, rain quickly follows. When the wind makes a whistling or howling noise, it is as sure a prognostic of rain as the wind can afford. A *brisk* south wind,

dry. Wind may be expected from that quarter or the opposite, if the clouds, as they come forward, seem to diverge from a point in the horizon. Wind from north-east to north-west, fair; from south-east to south west, rainy. A week's fair weather, with a southerly wind, drought; an easterly wind the fore part of summer, dry summer; westerly the latter part of summer, dry autumn.

*Dew.*—A heavy dew, fair. If it vanishes suddenly or early, rain. When the dew lies plentifully upon the grass after a fine day, another fine one may be expected to succeed it; but if, after such a day, no dew is upon the ground, and no wind stirring, it is a sign that the vapours ascend, where they will accumulate, and must terminate in rain.

*Vapours.*—A misty morning, and the mist falls, a hot day; if the mist rises, rain. If general before sun rise, near the full of the moon, fine weather.

Where there are high hills, and the mist which hangs over the lower lands in a morning draws towards the hills, and rolls up their sides until it covers their tops, there will be no rain.

To judge correctly of the appearance of a fog, it is necessary to be acquainted with the nature of the country, as, in some places, if the mist hangs upon the hills and drags along the woods, instead of overspreading the level ground in a morning, it will turn to rain. The contrary, when it comes down from the hills and settles in the vallies.

There is commonly either a strong dew or a mist over the ground between a red eve and a gray morn; but if a red morning succeeds, there is no dew.

If a white mist in an evening or night is spread over a meadow through which a river passes, it will be drawn up by the next morning's sun, and the day afterwards will be bright.

When a rainbow appears in the morning, rain; in the evening, fine. The frustrum of a rainbow, rain; predominantly red, wind; green or blue, rain; appearing in boisterous weather in the north, fine.

Lightning without thunder, after a clear day, is a sign of the continuance of fair weather.

*Sky.*—When those vapours which the heat of the day exhales from the earth are precipitated by the cold night, then the sky is clear in the morning; but if they still remain in the air, rain may be expected.

A dark thick sky, lasting for some time, without either sun or rain, changes to a fair clear sky before it turns to rain.

When a lowering redness spreads far upwards from the horizon, either in the morning or evening, it is succeeded either by rain or wind, frequently by both; and when a fiery redness, with rugged clouds, extends towards the zenith in an evening, a high wind from the west or south-west, attended with rain, follows; when the sky is tinged with a sea-green colour near the horizon, when it ought to be blue, rain will continue and increase; when of a dead blue, it is abundantly loaded with vapours, and will be showery.

When the canopy is high, fair; low rainy; orange coloured in the morning, rain; deep blue ground, fair; pale blue, rainy.

One observation is general, we believe, all over Europe—"the evening red, the morning gray, are sure signs of a fair day;" and it is founded upon this circumstance, that if the abundance of vapours denoted by the red evening sky descends in dew, or is otherwise so equally dispersed in the air that the morning shall appear gray, a fine day may be expected from that equal state of the atmosphere.

If in a morning some parts of the sky appear green, between the clouds, whilst the sky is blue above, stormy weather is quickly approaching.

*Sun.*—Rising orangy, rain; rising red and fiery, wind and rain; cloudy, and the clouds decrease, certain fair weather; rising dimly, drizzly. If the sun's rays breaking through the clouds are visible in the air, it is a proof that the air is sensibly filled with vapours, which reflect the rays to the sight, and these vapours will soon produce rain. When there is a haziness aloft in the air, so that the sun's light fades by degrees, and his orb looks whitish and ill defined, it is one of the most certain signs of rain.

Sun setting foul, rain; red, wind or rain; blue, rain; dusky, streaked with red, storm; purple, fine; bright, fine; when the sun appears white at setting, or goes down into a dusky bank of clouds, it portends the approach and continuance of bad weather.

*Moon and Stars.*—When the moon and stars grow dim in the night with a haziness in the air, and a ring or circle appears round the moon, rain is at hand.

If the moon looks red, it is a sign of wind; if pale and dim, of rain; if white

and of her natural colour, with the sky clear, of fair weather.

Should the moon be rainy throughout her course, it will clear up at the ensuing change, and rain will probably fall in a few days after and continue; if, on the contrary, the moon has been fair, and at the change it rains, fine weather will, in all likelihood, be restored about the fourth

or fifth day of the moon, and be of some duration. When the moon is bright with sharp tips, fair; new moon not appearing till the fourth day, rainy month; the lower horn of the new moon sullied, foul weather before the full; the middle, storms about the full; the upper horn, foul about the wane. Saturday's moon, rainy month.

But four nights old (for that's the surest sign)  
With sharpened horns, if glorious then she shine,  
Next day, not only that, but all the moon,  
'Till her revolving race be wholly run,  
Are void of tempests.

DRYDEN.

*Atmosphere.*—Cold after rain, rain; cold in summer, rain; warm in winter, rain; sultry in summer, thunder; heavy, fair; light, rain; moist, rain; dry, fair.

*Rain.*—Sudden rain seldom lasts long; coming on gradually and when the air grows thick by degrees, and the sun, moon, or stars, shine more and more dim, it is likely to continue six hours. Beginning with a high southerly wind and the wind subsides, rain for twelve hours or more, and sometimes continues until a strong north wind clears the air; beginning before sun-rise, will end before noon; a shower before sun-rise, a fine day usually succeeds; beginning an hour or two after sun rise, a rainy day; setting in wet between eleven and twelve o'clock, a rainy afternoon; clearing up about that time, the afternoon fine; cold wind after rain, more rain; a squall, or rain, or hail, settled fair; a rainy Friday, the same weather on Sunday; and a wet sabbath is frequently followed by a daggly week.

Sounds, such as bells, noise of waters, beasts, birds heard distinctly from a great distance, portend rain. If the earth, or any fenny places, yield any extraordinary scents, or any disagreeable smells arise from drains, rain. A white frost, rain within three days; the more than usual sinking of rivers, presages rain. The speedy drying of the surface of the earth

denotes a northerly wind and fair weather; and its becoming moist, southerly wind and rain; for the air sucks up all the moisture on the surface, even though the sky be overcast, and that is a sure sign of fine weather; but if the earth continue damp, and water stand in shallow places, no trust should be put in the clearest sky; for, in this case, it is deceitful.

*Animals.*—If cattle or sheep feed greedily and faster than ordinary when it rains, it is a sign of the rain's continuance; and when sheep skip and play wantonly, rain is at no great distance. In the mountainous parts of Derbyshire, called the Peak, the inhabitants observe, that if the sheep wind up the hills in the morning to their pasture, and feed near the tops, the weather, although cloudy and drizzling, will clear away by degrees, and terminate in a fine day; but if they feed in the bottoms, the rain will continue and increase. Geese and ducks more noisy, and washing and diving more than usual, rain; cock crowing in the middle of the day, and peacock squalling much, rain; kites hovering high in the air, fine weather; owls screaming frequently in the evening when foul, fair and frosty; when larks rise high and sing long, fine:—Bloomfield has beautifully noticed the soaring of the lark:—

When music waking, speaks the skylark nigh:  
Just starting from the corn she cheerly sings,  
And trusts, with conscious pride, her downy wings;  
Still louder breathes, and in the face of day  
Mounts up, and calls on Giles to mark her way.  
Close to his eyes, his hat he instant bends,  
And forms a friendly telescope, that lends  
Just aid enough to dull the glaring light,  
And place the wand'ring bird before his sight:

Yet oft beneath a cloud she sweeps along,  
 Lost for a while, yet pours her varied song ;  
 He views the spot, and as the cloud moves by,  
 Again she stretches up the clear blue sky :  
 Her form, her motion, undistinguished quite,  
 Save when she wheels direct from shade to light,  
 The flutt'ring songstress a mere speck became.

The redbreast singing loud in the open air is an indication of fine weather ; faintly, under cover, rain. Swallows skimming the surface of waters, rain : so long as they keep aloft after their prey, the sky is serene ; but when they descend and flit along the surface of the earth or water, rain is not far off. A drought, of three months' duration, broke up at the summer solstice, in 1775 : the day previous to the rain falling, the swallows flew very near the ground, which they had never done during the whole period of the dry weather. Sparrows chirping much in a fine morning, rain ; and the chaffinch being loud in his call, or note, is a pretty certain signal that wet is fast approaching.

Dogs are said by some to be particularly sleepy, and to eat grass, before rain ; but grass is a salutary vomit which nature prompts them to take at all times, when their stomachs require such an evacuation ; of course, it is not an unerring proof that the approach of rain alone drives them to seek this remedy. Moles throwing up more earth than usual, and its being small and dry, and their appearance sometimes above ground, rain. Worms creeping in numbers out of the ground, rain : and from the same principle that they, as well as moles, are sensible of the access of something new in the atmosphere, and to the surface of the earth. Frogs appearing of a golden hue, fine ; dusky colour, rain : and toads, in an evening, crawling over the road or beaten path, where they are seldom seen, but when restless from the expectation of approaching rain. Fishes are supposed to be affected, since they cease to bite freely, when rain is depending. All sorts of insects are more stirring than ordinary against rain. Bees are in fullest employ, but, if likely to rain, confine their industry to where they can reach their hives before the storm comes on ; when they fly far abroad, and stay out late, fine. When the common flesh flies are more bold and greedy, rain ; when small flies flock together in great numbers about the beams of the sun a little before it sets, fine. Ants bustle more than usual, move their eggs to dry

places, and then retire to their burrows, before rain falls. Gnats playing in the open air, heat ; when they form a vortex in the shape of a column, it announces fine weather ; when they collect and dance in the shade, showers ; and when they sting much, cold and rain. Spiders crawling abroad, rain. Bats flying more numerously and more early in the evening, fine. Glow worms appearing in unusual numbers, fine.

Most vegetables expand their flowers and down in fair weather, and close them again before rain ; this is visible in the down of the dandelion, and eminently so in the flowers of burnet, the opening and shutting of which is the countryman's weather glass, in some parts of England, for the following day :—if the flowers are close shut, rain ; spread open, fair.

The stalk of trefoil grows more upright and swells against rain ; similar, although perhaps not so sensible, is the effect on other plants. That vegetables should be affected by the same causes that affect the weather is very conceivable, considering them as so many hygrometers and thermometers, consisting of an infinity of air vessels (and which are visible in the leaf of the vine, scabious, &c.) by which they have an immediate communication with the air, and partake of its moisture and heat ; hence it is that all wood, even the hardest and most solid, from the vapours early insinuating themselves into the pores, swells in moist weather, especially that which is lightest and driest.

Chronic pains being more violent than usual, rain in summer, frost in winter. A disagreeable languor is generally felt before thunder.

A serene autumn denotes a windy winter ; a windy winter, a rainy spring ; a rainy spring, a fine summer ; a fine summer, a windy autumn : but it is very rarely that the seasons succeed each other in the same tenor for two years together. It has been remarked, that, if at the beginning of the winter, the south wind blow, and then the north, it portends cold ; but should the north wind first blow, the winter will be mild. A hot and dry September, a cold spring ; sum-

mer moist and cool, a hard winter: if walls that used to be damp are peculiarly dry at the commencement of winter, a hard winter may be predicted, for it shews a dry air, which, in winter, is always joined with frost. The early arrival of woodcocks, fieldfares, and other birds of passage, as they prove the cool tempera-

ture of the weather from whence they came, are also said to predict a cold winter in this country. The cuckoo, from its coming early, denotes that a hot summer will follow. Acorns and haws in plenty, a long severe winter. Nuts plentiful and the broom and almond tree full of blossom, foretel an abundant harvest.

Mark well the flowering almonds in the wood,  
If od'rous blooms the bearing branches load;  
The glebe will answer to the sylvan reign,  
Great heats will follow, and large crops of grain.

DRYDEN.

Animals are affected by rain, wind, &c. and in a variety of instances, afford notice of their approach.

The leech, kept in a common eight-ounce phial, three-fourths filled with water (changed once a week in summer, and twice in winter), and covered with a bit of linen rag, is a sure prognosticator of the alterations in the weather. The following are its indications:—In serene weather, it lies rolled up at the bottom, in a spiral form. When it is about to rain in the forenoon, it creeps to the top, and remains there, till the weather is settled. Previous to wind, it keeps in rapid motion, and seldom rests, till it begins to blow hard. If a remarkable storm of thunder and rain is to succeed, it lodges some days before continually without the water, and is very uneasy and convulsed. In frost, as well as in clear weather, it lies at the bottom; and in snow or rain, it keeps at the mouth of the phial.

In the account of animal barometers, this anecdote is remarkable. A gentleman, some few years since, brought a pointer dog, from South Carolina, who was a prognosticator of bad weather.—“Whenever I observed him (says his

master) prick up his ears in a listening posture, scratching the deck, and rearing himself up, to look over to the windward, where he would eagerly snuff up the wind, though it was the finest weather imaginable, I was sure of a succeeding tempest; and this animal was grown so useful to us, that whenever we perceived the fit upon him, we immediately reefed our sails, and took in our spare canvas, to prepare for the worst.”

It is a sign of rain, when the soot collected round pots or kettles, takes fire, in the form of small points, like grains of millet, because this phenomenon denotes, that the air is cold and moist.

The moon is supposed to have influence on the weather. The following table, ascribed to the illustrious astronomer, Dr. Herschel, is constructed upon a philosophical consideration of the attraction of the sun and moon in their several positions, respecting the earth; confirmed by the experience of many years' actual observations, and will, without trouble, and with great truth, suggest to the observer, what kind of weather will follow the moon's entrance into any of her quarters.

NEW OR FULL MOON.	SUMMER.	WINTER.
If it be <i>new</i> or <i>full</i> moon, or the moon enters into the <i>first</i> , or <i>last</i> , quarters at the hour of 12	Very rainy . . . .	Snow and rain.
Or between the hours of		
2 and 4 . . . . .	Changeable . . . . .	Fair and mild.
4 . . 6 . . . . .	Fair . . . . .	Fair.
6 . . 8 . . . . .	{ Fair, if wind N. W. }	Fair & frosty, if N. or N. E.
8 . . 10 . . . . .	{ Rainy, if S. or S. W. }	Rainy, if S. or S. W.
10 . . Midnight . . . .	Ditto . . . . .	Ditto.
Midnight . . 2 . . . .	Fair . . . . .	Fair and frosty.
2 . . 4 . . . . .	Ditto . . . . .	{ Hard frost, unless wind }
4 . . 6 . . . . .	Cold, with freq. showers	S. or S. W.
6 . . 8 . . . . .	Rain . . . . .	Snow and stormy.
8 . . 10 . . . . .	Wind and rain . . . .	Ditto.
10 . . Noon . . . . .	Changeable . . . . .	Stormy.
	Frequent showers . . .	Cold, rain if W. snow if E.
		Cold, with high wind.

In extracting these remarks it may not be amiss to observe, that every season has its peculiar characteristic, and it is asserted by an intelligent observer, that the same augury which in a fair season foretels fair, will, in a rainy one, pre-sage wet weather; therefore the characteristic of the season ought to be pointed out before the quality of the weather can be prognosticated.

**PROPORTIONS OF POWDER AND SHOT.** The quantity of powder and shot which constitutes the correct load or charge for the fowling-piece, is a circumstance which ought to be duly impressed on the mind of every shooter, and to which, I am inclined to think, not sufficient attention is generally paid. On trial, it will be found that all guns shoot the strongest the first discharge, or, in other words, when they are perfectly clean, and that the force decreases in exact proportion as the piece becomes foul; hence the necessity of occasionally wiping out the barrel during a long day's shooting. There is also a certain proportion of powder and shot which will exactly suit every fowling-piece; and to ascertain this should be the first object with all new guns. If a piece be overloaded with powder, the shot will scatter very much, and but few pellets will strike the object; whereas, if an insufficient quantity of powder be used, the shot will not be driven with sufficient force. Yet, it is more than probable, that a trifling variation will be found in all guns; or, to speak more plainly, it will be a difficult matter to find two pieces, though of the same

length and calibre, which require precisely the same charge. A very good method of ascertaining the proper load for a fowling-piece is by firing at sheets of paper at given distances, and the progressive result will guide the shooter in the increase or decrease of either the powder or shot, or both.

On investigation it will probably be found, that the general error in loading the fowling-piece, is using too much powder, which not only very much scatters the shot, but renders the recoil almost insupportable,—it is quite a mistaken notion to suppose that a distant object will be better reached with a large load of powder, or that the force of the shot is thus increased; as it will be found, on experiment, that those pellets which strike the mark are not so strongly driven as when a reduced, but a correct, portion of powder is used, to say nothing of the scattering of the shot, by which a small object will generally be missed. Hence it is highly necessary that the correct charge should be ascertained, and uniformly adopted.

**PROVING GUN BARRELS.** See FOWLING-PIECE.

**PTARMIGAN.** See GROUSE.

**PULSE.** This momentary increase of capacity in the artery (says Blaine) whereby its diameter is enlarged, is called its pulse; and the more frequent are these dilatations in it, or the less numerous, so is the pulse quicker or slower. The circulation being slower in all large animals than in small, the standard, i. e. the healthy pulse of the horse, is from 45 to 50;

in the human from 68 to 75 ; and in the dog from 90 to 110. In young animals, the weakness of the system, and its irritability are considerable, hence they have a much quicker pulse ; the colt's pulse is from 60 to 65 ; the human infant's beats more than 110 : this gradually lessens to the adult period, when it follows nearly the standard we have noticed. As the heart of a large animal has a longer way to send its blood, and its resistance is consequently increased, so it takes a longer time to accomplish its contraction ; and thus there is not only a difference between the different species of animals, but between individuals of the same species as they vary in size ; from which, the smaller the horse, the quicker will be the pulse.

As very few active diseases can exist in the body without disturbing the circulation, by either accelerating, retarding, or interfering with its regularity ; so the pulse has been resorted to as furnishing a criterion of the nature and severity of the disease ; not altogether invariable or arbitrary, but sufficiently so to deserve the most serious attention of the veterinarian, who will find it, in cases of danger and obscurity, frequently his only practical guide. To a due consideration of the state of the pulse, not only the immediate state of the disease itself, but many surrounding circumstances, must be taken into the account. A cold temperature will lessen the circulation ; a particular irritability of the system in some horses quickens their pulse ; and the action of fear materially influences it, for which reason great caution is necessary to avoid alarming the animal, or the pulsating vessel may present a wrong indication. The circulation being universal, and the motions of the blood being uniform, it follows not only that the pulse may be felt in every part of the body, but that the pulsations are synchronous. It is, therefore, of little importance where the pulse is felt, provided we have the opportunity of pressing the pulsating artery against some hard body, or of actually embracing it between the finger and thumb ; which, however, is seldom to be done. Bartlet recommended the pulse to be felt by the leg, by the carotids, or by the heart itself. Mr. Clark describes it as most easily felt at the origin of the temporal artery at the base of the ear.

A *full strong pulse*, where the resistance to the pressure of the fingers is very considerable, giving a bounding stroke, and evidently betokening an increase of

the diameter of the artery, seldom exists in the diseased horse. Some natural excitements may bring it on, as lust, exercise, &c. The full pulse of the horse, under the highest inflammatory affections has always some confined vibratory hardness, and never gives the full bounding feel, present in these cases in the human : thus, though the pulse presents a much more unerring criterion of the state of the disease than that of man, yet the analogy is by no means perfect between them. In treating therefore on diseases, whenever the term *full pulse* occurs, it must be considered as intended to convey the above idea only.

A *hard pulse*, with increased frequency, is the most common in the inflammatory affections of the horse, in which case the arterial action is stronger, with diminished diameter of vessel. It is detected by the peculiarity of feeling, like a cord vibrating under the finger, and not like the full undulations of an overcharged vessel. This vibratory hardness, with increased frequency, is the usual attendant on the active stages of visceral inflammations. In the more early stages of peritoneal inflammation of the intestines, or red colic, it is the great characteristic between that and the spasmodic colic or gripes : for in the latter, although after a few hours' continuance there is often some hardness in the pulse, it is always accompanied, when purely spasmodic, with a degree of fulness also, unknown to the other. This pulse is common to all inflammations of parts less essential to life, as of the cellular membranes, muscles, skin, &c. when sufficiently violent to affect the constitution. It accompanies the early stages of bad catarrhal affections, and occasionally of pneumonia also ; but in the former it usually exhibits more frequency than in the latter.

The *wiry pulse* is a very important modification of the hard, in which the sensation is contracted from that of a vibrating cord to that of a jarred wire, whence its name of wiry, thready, &c. It is commonly accompanied with increased frequency, but by no means invariably so ; and is often present in the protracted stages of visceral inflammation, and in some few it accompanies them from their outset. It appears to be the common consequence of the former pulse, and thus succeeds to it so frequently in the secondary or protracted stages of all inflammatory affections of magnitude ; particularly of such as commence slowly.

The *oppressed pulse* is also a modification of the hard pulse, and appears the consequence of the opposing efforts of the muscular and elastic portions of the artery ; the efforts of the one appearing to be employed to restrain the distension forced on the other by a congestion within some part immediately concerned in circulation. It is from this cause that it is so common to the active stages of pneumonia, or inflammation of the lungs ; and it is probable that, when it is present also in other visceral affections, it arises from the secondary effect produced on the respiratory organs. When the difficulty is in a certain degree removed to the transit of the blood through the right side of the heart, by abstracting a large quantity of it, and thus removing the congestion ; it is remarkable how this oppressed pulse, creeping, labouring, and often slow, will rise into a more full, free state, but still with remnants of its parent hardness remaining ; and as long as such alteration is produced by bleeding, it is prudent to pursue it.

A *small pulse* is usually present in all cases of great debility, and is generally attended with increased frequency. When it is very small and thread-like, it shews that the debility is extreme, and prognosticates a fatal termination of the existing disease, the heart and arteries attempting to make up by quickness what they want in strength. If with this degree of smallness it vary in its regularity, or intermit, it is even more certainly a fatal prognostic. We must be careful not to be misled by a small *oppressed* pulse frequently present in inflammation of the vital organs, particularly of the chest, to mistake this for a pulse of debility. The distension of an artery may be so great as to overcome its contracting power, as any elastic body may be distended beyond its tone or capability of recovery ; hence a small pulse is not always a sign of general debility : for in inflammation of the vital organs, this distension of the vessels frequently takes place to such a degree as to prevent their natural contraction ; and a small pulse is by this means produced : but if the over-distending column be removed by copious bleeding, the over-stretched muscular coat recovers its tone, and can contract on its contents ; and thus, in such cases, the pulse is found to rise on bleeding. The bladder, we know, under long retention of urine, becomes so distended as to be incapable of contracting on its contents,

and, unless it be artificially emptied, the muscular coat will give way and burst. It is therefore probable, that an inflamed part is not in a state of increased strength, though it is of increased action, but on the contrary ; for as the vessels are preternaturally distended, they are in consequence weakened : hence, in some local inflammations, or where the vessels of a part only are under this state of increased action, topical bleeding, by emptying those particular vessels, will often prove highly useful ; while, on the contrary, general bleeding may, in the same case, be prejudicial, because, by weakening the system in general, it must still further weaken those particular vessels, and render them less able to contract. We may, therefore, learn that instances do occur where diminishing the general strength may augment the inflammation.

A *quick pulse* usually denotes irritability in the system ; but there may be natural or common causes for such quickness of pulse ; as youth, diminutive size, fatigue, a hearty meal, or a particular temperament ; but when none of these natural causes are present, great quickness of the pulse proves a diseased irritability of the vascular system, and often a want of power also. But its indication becomes very different as it is accompanied by fullness or smallness. When the frequency of the pulse is considerable, with an increase of strength in the action of the artery, it may be gathered, from what has already been said, to betoken inflammatory action, general or local.

A *slow pulse* may be occasioned by pressure on the brain from the effect of accidents, or from congestion, as in lethargy, sleepy staggers, epilepsy, &c. It may also be brought on through the medium of the stomach by various substances taken in. White and black hellebore, aloes, digitalis, hemlock, and whatever excites nausea, decreases the frequency of the pulse in the horse as in the human. But unfortunately, in the horse, our means of exciting this sensation are usually limited to such matters as are in themselves sources of great irritation, and hence hurtful. Neither is a simple alteration in the frequency all that is necessary. To a beneficial end we should render the pulse soft also, without which a slow pulse may retain its inflammatory base, as we witness in the lethargy of staggers.

A *soft pulse* is in all its characters the

reverse of the hard, the full, or the oppressed. It is frequent at the decline of inflammatory affections, and usually shews the cessation of the inflammatory diathesis; thus, after the hot fit of fever is removed, the pulse, from being hard, becomes soft. Suppuration, as a termination of inflammation, also produces it; and whenever there has been great local inflammation, and pus forms, the slow pulse is generally present.

A *regular pulse* is sometimes found under very diseased affections; but it is usually increased in its fullness or smallness, or in its hardness or softness: a regular pulse, with a proportionate fullness, is one of the strongest marks of health; as an irregularity may be occasioned by organic affection; that is, by a peculiar formation of parts, or some disease about the heart, as ossification of its valves, or of the larger vessels.

*Irregularity* in the pulse is a mark of great irritability, and when not arising from any organic affection, it is a mark of great debility also. Inflammation of the heart is usually accompanied by great irregularity in the pulse, with extreme oppression and smallness; the heart contracts several times, and then stops till more blood be sent to it. An *irregular*

*pulse*, in fever, shews great danger: it usually accompanies mortification and gangrene; and when inflammation of the lungs terminates in this way, this pulse is usually present. A very peculiar irregularity of the pulse is also present when a serous fluid is thrown out into the chest after these inflammations; in which cases, besides its intermission, the pulse appears as though undulating through a bladder of water. This pulse should be particularly noticed, as, when once felt, it need never be forgotten.

PURGING HORSES. See PHYSICING.

PURLIEU. All that ground near any forest, which, being anciently made forest, is afterwards, by perambulations, separated from the same, and freed from that servitude which was formerly laid upon it.

PURLIEU-MAN. One that has land within the purlieu, and forty shillings a year freehold; upon which account he is allowed to hunt or course in his own purlieu, with certain limitations.

PURSE-NET. A net in the form of a purse, used for taking both hares and rabbits. The purse-net is frequently used by the poacher for catching hares, instead of the wire snare; it is also used with the ferret in netting rabbits.

## Q

QUAIL. This bird is an inhabitant of nearly all the countries in the world, and is every where esteemed excellent food. In appearance it is so much like the partridge, as to be in some places called the *dwarf partridge*; and in the manners of the two species there is a great resemblance. They form their nests and rear their young nearly in the same way. They are, however, in many respects very different. Quails migrate to other countries; they are always smaller; and have not a bare space between the eyes, nor the horse shoe, or crescent, figure on the breast. The eggs too are less than those of the partridge, and very different in colour. Their voices are unlike. Quails seldom live in covies, except when their wants unite the feeble family to their mother, or some powerful cause urges at once the whole to assemble, and traverse together the extent of the ocean, holding their course to the same distant lands. They are much less cunning than the partridge, and more easily ensnared, especially when young. Their disposition is not so gentle as that of the partridge.

Quails are found in most parts of Great Britain, but not very numerously, and they are seldom seen in the midland counties. It appears that one circumstance which determines their abode in this

country is plenty of herbage ; since, in a dry spring, when grass is consequently scarce, few quails are to be met with.

The females lay ten or twelve eggs, in the incubation of which they are occupied three week. The eggs are whitish, but marked with ragged rust-coloured spots. Quails have been supposed, but without foundation, to breed twice in the year.

It is said that quails usually sleep during the day concealed in the tallest grass ; lying on their sides, with their legs extended, in the same spot, even for hours together. So very indolent are they, that a dog must absolutely run upon them before they are sprung ; and, when they are forced upon the wing, they seldom fly far. Quails are easily drawn within reach of a net, by a call, imitating their cry, which is done with an instrument called a quail pipe, which is rarely, if ever, used in this country, having been superseded by the fowling-piece.

Quails visit this country in spring, and generally leave it again in the latter end of September ; they are sometimes found here later, and, if the accounts are to be depended on, instances are not wanting, where they have remained the whole year. They are supposed to winter in Africa. If to the circumstance of their generally sleeping in the day, is added that of their being seldom known to make their first annual appearance in the day time, it may be inferred that they perform their journey by night, and that they direct their course to those countries where the harvest is preparing, and thus change their abode to procure a subsistence. On their arrival at Alexandria, such multitudes are exposed in the markets for sale, that three or four may be bought for a medina (less than three farthings.) Crews of merchant vessels have been fed upon them ; and complaints have been laid at the consul's office by mariners against their captains for giving them nothing but quails to eat.

With wind and weather in their favour, they have been known to perform a flight of fifty leagues across the Black Sea in the course of a night ; a wonderful distance for so short-winged a bird.

Such prodigious quantities of quails have appeared on the western coasts of the kingdom of Naples, in the vicinity of Nettuno, that a hundred thousand have, in one day, been caught within the space of three or four miles. Most of these are taken to Rome, where they are in great request, and are sold at high prices. Clouds of quails also alight in spring along the coasts of Provence ; especially on the lands which border on the sea. Here they are sometimes found so exhausted, that for a few of the first days they may be caught with the hand. In some parts of the south of Russia they abound so greatly, that, at the time of their migration, they are caught by thousands, and sent in casks to Moscow and Petersburg.

It seems that great quantities of these birds are imported from France. They are conveyed by stage coaches ; about one hundred in a large square box, divided into five or six compartments, one above another, just high enough to admit the quails to stand upright. Were they allowed a greater height than this, they would soon kill themselves ; and even with this precaution the feathers on the top of

the head are generally beaten off. These boxes have wire on the fore part, and each partition is furnished with a small trough for food. They may be forwarded in this manner, without difficulty, to great distances.

With respect to these birds having an instinctive knowledge of the precise time for emigration, we have a very singular fact in some young quails, which had been bred in a state of confinement from the earliest period of their lives, had never enjoyed, and therefore could not feel the loss, of liberty. For four successive years, they were observed to be restless, and to flutter, with unusual agitations, regularly in September and April; and this uneasiness lasted thirty days at each time. It began constantly about an hour before sunset. The birds passed the whole night in these fruitless struggles; and always on the following day appeared dejected and stupid.

Quails are birds of undaunted courage, and their quarrels often terminate in mutual destruction. This irascible disposition induced the ancient Greeks and Romans to fight them with each other, as the moderns do game cocks. And such favourites were the conquerors, that, in one instance, Augustus punished a prefect of Egypt with death for bringing to his table one of these birds which had acquired celebrity for its victories:—so at least it is recorded; but, when the character of Augustus is taken into consideration, the account appears scarcely entitled to credit.

Sometimes combats, we are told, were performed between a quail and a man; the quail was put into a large box, and set in the middle of a circle traced on the floor; the man struck it on the head with one finger, or plucked some feathers from it: if the quail, in defending itself, did not pass the limits of the circle, its master won the wager; but if, in its fury, it transgressed the bounds, its antagonist was declared victor.

The Chinese use this bird, it is said, whose body is very hot, to warm their hands in cold weather; and among the French “*Chaud comme un caille*—warm as a quail,” is a proverb.

Quails, where they can be found, afford good practice to the young shooter: they fly straight and seldom far; and thus many shots may be obtained with little difficulty.

The length of the quail is seven inches and a half, breadth fourteen; bill dusky; the feathers of the head, neck, and back, are a mixture of a brown ash-colour and black; the crown of the head divided by a whitish yellow line, beginning at the bill, and running along the hind part of the neck to the back; above each eye is another similar coloured streak; a dark line passes from each corner of the bill, forming a kind of gorget above the breast; the chin, throat, belly, thighs, and vent, dirty yellowish white; the scapular feathers, and those of the back, are marked in their middles with a long light yellow streak, and on their sides with ferruginous and black bars; the coverts of the wings are reddish brown, elegantly barred with paler lines, bounded on each side with black; the quills are lightish brown, with small rust-coloured bands on the exterior edges of the feathers; the breast is of a pale rust-colour, spotted with black, and streaked

with pale yellow ; the tail consists of twelve short feathers, barred with black and very pale brownish red ; the legs are pale brown.

The female differs from the male in having no black spots on the fore part of the neck, breast, and side feathers, and from the colours being less vivid. Some of them have a long spot of brown beneath the throat.

**QUALIFICATION.** See **GAME LAWS.**

**QUALIFICATIONS** appertain, in a particular degree, to the subject of racing upon the turf, and are used in a certain signification. Plates of 50*l.* are given at numerous places of sport, to be run for on certain conditions ; some by colts, and fillies of three years old ; some four years old ; others five and six ; and, lastly, for horses of all ages and qualifications. The precise meaning of which is, that a horse equal in age to one or more of his competitors, may be very superior in qualifications ; in which case, it becomes necessary and equitable to bring their abilities more upon an equality, by so increasing the weight which one is to carry above the standard of the other, that there may be left very little probability of deciding upon the certainty of superiority in speed, when the impartial and judicious adjustment of weight is so properly fixed, as to leave an equal hope and expectation of winning the prize for which they are to start. To render such mode the less liable to objection, it is mostly the custom to say in the advertisements, a winner of one plate in the present year to carry 3*lb.*, the winner of two, 5*lb.*, and of three, or more, 7*lb.* extra.

**QUARTER, FALSE.** The defect so called in the hoof of a horse, is the renovated part of what has been by some accident previously destroyed ; and this effort of nature being inadequate, in its regeneration, to the original formation, the quarter of the heel, in its growth, acquires a kind of spungy puffiness or elasticity, accompanied by a cleft or crack, which prevents a perfect and undivided union with that part of the hoof uninjured, constituting a tender weakness, as well as a permanent blemish, not to be obliterated during the life of the horse. Notwithstanding which, much depends upon the management during the time the original injury remains in its infant state. A wanton destruction of parts, by the too hasty and injudicious interposition of caustics and cutting knives, frequently does more mischief in twelve hours, than nature, with all her powerful endeavours, can repair in as many months. When by

these, or other means, a false quarter cannot be avoided, it should be occasionally attended to during the progress of its growth : the uneven prominences should, when becoming luxuriant and irregular, be kept down by gentle rasures with the rasp, and the surface, the cleft, and surrounding part, be plentifully moistened with friar's balsam, tincture of myrrh, or some such applicable substitute, as may give it a gradational hardening, and effectually reduce the irritability of the parts affected. To relieve the ill-effect of this inconvenience to a certain degree, a bar-shoe may be so carefully constructed, as to shield the tender and weaker part of the hoof from pressure ; and this can only be done by forming the shoe of such thickness, as to admit of its taking its bearing equally from the sound parts of the hoof, about an inch or two on each side the seat of injury, with strength sufficient to prevent a chance of its indentation upon the tender part intended to be protected.

**QUARTERS.** The fore and hind parts of a horse are frequently so called ; for instance, such a horse is beautifully formed in his fore quarters, but he is exceedingly ill made behind ; and some are well proportioned in the gaskins, the hip, the rump, and hocks ; but are ill formed and low before. The fore quarters include the head, neck, breast, withers, and fore legs, to the girths ; the hind quarters comprehend the hips, thighs, hams, hocks, and hind legs.

**QUEST.** Seeking for game.—Harriers are said to have *got a quest* when they give tongue after coming upon a trail. The term is also applied to spaniels in covert.

**QUITTOR, QUITTER, OR QUITTERBONE.** An ulcer formed between the hair and hoof, usually on the inside of a horse's foot. It arises often from treads and bruises ; sometimes from gravel, which, by working its way upwards, lodges about the coronet. If it is only superficial, it may be cured with cleansing dressings, bathing the coronet every day with lime water, and dressing the sore with precipitate. But if the matter

forms itself a lodgment under the hoof, there is no way then to come at the ulcer but by taking off part of the hoof; and if this be done well, the cure may be effected without danger.

When the matter happens to be lodged near the quarter, the farrier is sometimes obliged to take off the quarter of the hoof, and the cure is then for the most part but palliative; for when the quarter grows up, it leaves a pretty large seam, which weakens the foot: this is what is called a false quarter; and a horse with this defect seldom gets quite sound.

If the matter, by its confinement, has injured the coffin bone, which is of so soft and spongy a nature that it soon becomes carious, it will be necessary to enlarge the opening, cut away the spongy flesh, and apply the actual cautery, or hot iron pointed pyramidically. Afterwards dress the bone with dossils of lint dipped in tincture of myrrh, and the

wound with the green or precipitate ointment. When the sore is not enlarged by the knife, which is the best and less painful method, sublimate is generally applied, or blue vitriol powdered and mixed with a few drops of oil, which is said to act as effectually, and with less pain. During the operation of these caustics, the foot should be kept in a common soft poultice. If sinuses form, they must be laid open, and afterwards stimulated by some sharp remedy. Mr. Denny recommends the following:

Take of Corrosive sublimate;

Red precipitate, in fine powder, of each equal parts;

Honey, sufficient to form a paste.

He directs the wound afterwards to be dressed with common digestive ointment; and advises pressure to be made by a bandage round the coronet.

## R

**RABBIT** is the well known little animal bearing a striking similitude to the hare in its formation; but is much less regarded as a luxury for the table. This animal is remarkably prolific; and Pliny observes upon the fruitfulness of animals, that nature has kindly befriended man by causing those to be most prolific that possess the least power of mischief, and are the most proper for his food. The instance he produces is the pigeon, which, from one pair, may increase in four years, to 14,760. Linnæus makes the number amount to more than 18,000. Rabbits will breed at six months old, bear seven times annually, and bring five young ones each time: supposing this to happen regularly during the space of four years, and that three of the five young at each kindle are females, the increase will be 478,062. The calculation has been made from eight young at each of the seven kindles, amounting to 1,274,840; but this is much too high, as five at each kindle is perhaps beyond the average for the wild rabbit. Under the first statement, being overstocked with these animals might justly be feared; but man, birds, and beasts of prey make great havock among them.

The rabbit prefers a temperate and warm climate, and endures great cold with difficulty. In Sweden they are obliged to be kept in houses. Spain is their native country. The island of Minorca is very remarkable for its growth of rabbits, but their flesh is so rank, that, instead of serving as food, they are an incumbrance to the people inhabiting it; who, to prevent the land from being over-run by them, are called upon by the Governor to give their assistance two days in every year to destroy them; and in the time of the Romans they once proved such a nuisance in all the Balearic islands that the inhabitants were obliged to implore the aid of a military force

## R A B B I T

from Augustus in order to exterminate them. Many parts of England abound with them. Lincolnshire, Norfolk, Suffolk, and Cambridgeshire, where the soil is sandy, are the counties in which they are most plentiful; whence immense numbers are brought for the supply of the London market. In Yorkshire, there are many warrens, and the rabbits supply the markets of Hull, York, and the neighbouring towns; and the skins are sold to the furriers at Stanford Bridge and Malton, who sell their wool to the hat manufactories of London and Manchester. Their fur is a material much used in making hats, and the English possess a peculiar mode of cutting the fur from the pelt.

The flesh of the rabbit is very good; but the best rabbits are those in covers, where the surrounding fields present a choice of food, which does not happen to those in warrens, where their food is chiefly mosses and the *carex* grass. Turnips are sometimes sown for them on warrens; and in severe weather, in winter, they are frequently fed with turnips. If turnips are pulled and carried on to the warren, from two to three large cartfuls will be sufficient provision for a thousand couple of rabbits for a day; and turnips are the best food in snows, as the rabbits can find them by the scent:—if hay be used, one load will suffice for a like number for the same period.

The rabbit finds it difficult to make its burrow on level ground, the mould being all to be thrown up to the surface; on the contrary, against the side of a steep hill, the animal has no difficulty to encounter; the declivity affords a ready fall for the earth, the work is all down hill, and there are perhaps few sandy or other loose soil'd hills, which would not be more profitable as a rabbit warren, than under any other course of husbandry. In situations where the ground, as well as the soil, is suitable for rabbit warrens, and where sufficient extent of contiguous and unseparate property can be procured, it may be most profitably stocked with rabbits; “for instance (says Mr. Marshall) the hide of a bullock (of some breeds) is not worth more than one twentieth of the carcase; the skin of a sheep may, in full wool, be worth from a sixth to a tenth of its carcase; but the fur of the rabbit is worth twice the whole carcase; therefore, supposing the rabbit to consume a quantity of food in proportion to the size of its body, it is, on the principle offered, a species of stock nearly three times as valuable as either cattle or sheep.” Experience, however, does not bear out these conclusions.

Until of late years, the grey rabbit was the only species; for some time back the silver haired rabbit has been sought after, and has been introduced into many warrens. The fur of the grey rabbit is cut from the pelt as a material for the manufacture of hats, whereas, that of the silver haired one is dressed as fur, and principally exported to the East Indies. The colour is a black ground, thickly interspersed with single white hairs. The skins of the latter of course sell for a higher price than those of the common sort.

The accuracy of persons taking stock upon the warren farms betwixt an incoming and outgoing tenant, is a matter of surprise: they attend for some days the appearance of the rabbits at the mouths of

## R A B B I T

their burrows, at dusk and earliest dawn (for in the middle of the day the rabbits keep in their holes;) and the judgment formed from this ocular proof of the apparent number is said to be so well calculated, that upon the destruction of many warrens, it has been established, beyond doubt or controversy, to have been extremely exact.

Warren farmers are sometimes liable to great losses from an epidemical disorder among the rabbits. The spring and summer of 1798 were so favourable to the breeding of rabbits, that the warrens in all parts were judged to have never been more plentifully stocked; but great numbers of the young ones perished by a disorder supposed to have been produced by a continual wet in the autumn. It was infectious; the first symptom was a swelling in the glands of the neck; the rot ensued, and death soon followed.

Some years ago, a gentleman of Sussex, in the neighbourhood of Chichester, tried the experiment of castrating rabbits, which so much increased their size, that, at six months old, when prepared for the spit, they have exceeded six pounds and a half in weight. It is described by him as a most profitable practice; the operation was performed when six or seven weeks old, and, out of three hundred, he never lost one. For proof of utility he frequently left one or two of a litter in their natural state, and uniformly found that those which were cut, at seven or eight months old, were nearly double the weight of the others, although partaking of exactly the same food, and all running about together.

Notwithstanding the similarity of the hare and the rabbit, nature has placed an inseparable bar to their complete resemblance, in not allowing their intermixture, to which they mutually discover the most extreme aversion: there is, moreover, a wide difference in their habits and propensities: the rabbit makes holes in the earth, where it brings forth its young, and retires from the approach of danger; while the hare prefers the fields, and trusts to its speed for safety. This management of the rabbit is alone sufficient to prove it superior to the hare in sagacity. The structure of both is the same, and enables them equally to dig retreats under ground; both are equally timid, but the talents of one being weaker than those of the other, he contents himself with a seat upon the surface of the ground, where he remains perpetually exposed; while the rabbit, endued with superior instinct, digs for himself an asylum in the earth. Their labour is unquestionably the effect of forecast, since domestic rabbits never give themselves the trouble of digging. It has often been remarked, that when a warren is attempted to be replenished with domestic rabbits, both they and their offspring remain, like the hares, upon the surface, and that they never begin to dig holes for their protection until after enduring many hardships, and having passed through several generations.

The rabbit, however, is much inclined to sit upon the ground. Those rabbits which are occasionally met with in the fields, form themselves a seat in which they sit in the same manner as a hare; but they have generally a hole or burrow at no great distance, to which they immediately run on being disturbed.

## R A B B I T

In speaking of the instinct of animals in giving notice of alarm to each other, Dr. Darwin remarks, that as rabbits cannot easily articulate sounds, and are formed into societies that live under ground, they have a peculiar method of giving alarm. When danger is threatened, they thump on the earth with one of their hinder feet, and produce a sound capable of being heard a considerable distance by animals near the surface, which would seem to be an artificial signal, both from its singularity, and its aptness to the creature's situation. The rabbits on the island of Sor, near Senegal, do not burrow; so that we may suspect their digging themselves holes in this cold climate is an acquired art, as well as their note of alarm.

The rabbit lives to the age of eight or nine years, and is capable of procreating at five or six months, and goes with young thirty or thirty-one days. In consequence of the male's unnatural dislike to its offspring, the doe frequently kindles out of the warren. She scratches a small burrow about two feet deep, where she prepares a bed for her young, composed of the fur plucked from her body, and some blades of grass; which the warreners call the rabbit's nest: here she suckles (which she always does at early morn and late in the evening) her young, and attends them for six weeks. At first, the hole which contains the young rabbits is completely closed up, so that the aperture cannot be readily discovered, during the day; as the young ones acquire strength, the hole is gradually opened; and at about the period before mentioned (six weeks) they are able to provide for themselves.

The Wold warreners catch their rabbits with fold nets, with spring nets, and with *tipes*, a species of trap.

The fold nets are set about midnight, between the burrows and the feeding grounds; the rabbits being driven in with dogs, and kept inclosed in the fold until morning.

The spring net is generally laid round a hay stack, or other object of inducement for rabbits to collect in numbers.

The tipe or trap is a more modern invention: it consists of a large pit or cistern, covered with a floor, with a small trap door, nicely balanced near the centre, into which the rabbits are led by a narrow meuse. It used to be set by a hay stack; but since turnips are now grown for the winter food, in an inclosure within the warren, the trap is placed within the wall of this inclosure. For a night or two, the rabbits are suffered to go through the meuse, and over the trap, they thus become familiarized to where the turnips are grown; after that the trap door is unbarred, and the number wanted is taken. In emptying the cistern, the rabbits are culled; the fat ones are slaughtered, and the others turned upon the turnips to improve.

At the close of the season, the bucks and does are sorted in a similar way; one male is considered as sufficient for six or seven females; and the nearer they can be brought to this proportion the greater produce of young may be expected.

Great precaution is necessary in using the traps: should too many rabbits be admitted at once, and the cistern be kept closely covered for a few hours only, suffocation, from intense heat, takes place, and

## R A B B I T

the carcasses, at least, are spoiled :—many thousand carcasses have been wasted through this means ; the traps are therefore carefully watched, and when the required number is caught, the mouse is stopt and the trap door fastened. Five or six hundred couples have not unfrequently been killed in one night, and there was once an instance in the Driffield warrens of fifteen hundred couple being slaughtered.

Rabbits are also taken with the ferret ; which, it is said, was originally brought from Africa into Spain, to free that country from the multitude of rabbits by which it was over-run. When the young rabbits are about half grown, the ferret is used with a line round him ; and, upon seizing one, he is drawn gently back, and holds the rabbit in his mouth ; but this can only be done where the holes have few angles, and are shallow. In winter, the ferret is coped or muzzled, and a small bell tied round his neck ; and afterwards the holes are as silently as possible covered with purse nets, called *flaus*, the ferret is put in the windward side of the burrows, where the person should also place himself, and observe the utmost silence, otherwise the rabbits will retreat to their lower earths, and suffer the ferret to scratch them to death before they will bolt. Hay nets are, however, chiefly used by experienced warreners, who are loath to turn ferrets into the burrows, as it invariably gives the rabbits a dislike to them. The time these nets are set is at day break ; and they let them remain till half an hour before sun rise ; and again, half an hour before sun set, until dark. The warreners drive to the nets with the wind if possible ; a side wind will do, but nothing is done if the wind blows over the net into the creature's face. A lurcher is often used to force the rabbits into the hays.

It is said, that sounding a trumpet in the burrows will make the rabbits start from them ; and some persons smoke the holes with brimstone and orpiment ; this will dislodge them ; but it is a very troublesome and offensive method ; and it is detrimental to the place, as no rabbit will, for a long time afterwards, come near the burrows that have been fumed with these fetid ingredients.

The Norfolk warreners use the following method to destroy kites and other birds of prey : these birds are very shy, and like to settle where they can have an uninterrupted view for some distance ; a naked stump or hillock is their favourite resting place ; the warreners, therefore raise mounds of earth of a conical form in different parts of the warren, and place steel traps upon the summits of these artificial hillocks.

Those who breed tame rabbits for sale keep them in hutches, which should be kept clean. The bucks and does should be kept apart until the latter have kindled, when they are turned to the buck, and remain until the doe runs from him—the general computation is one buck to nine does. The best food is the shortest and sweetest hay, of which one load will serve two hundred couple for a year. Tame rabbits are subject, first to the rot, which is the consequence of too much green food, or when it is gathered with dew or rain hanging upon it. Dry food is the remedy for this distemper. Secondly,

to a sort of madness, when they wallow and tumble about with their heels upwards; this is supposed to be owing to the rankness of their feeding; and the general cure is, the keeping them low, and giving them the tare thistle to eat.

Cartwright, in his Journal, whilst upon the coast of Labrador, makes the following mention of the rabbit: "I have got a buck and doe left (says he) of those which I brought from England; and as the latter has run loose about the house all winter, and kindled in a box in the dining room, I have had opportunities of making some observations on her and her young ones. She went twenty nine days with young; the young ones not only came into the world blind, but their ears were also shut, nor could they move them until the tenth day; on the eleventh, they began to see; on the twelfth, their ears were quite open; and on the thirteenth, they could erect their ears. The doe did not continue in the box from the time she kindled her first young one until she got quit of the last, but came out at intervals; nor did she ever after stay with them longer than a minute or two at a time to give them suck, always covering them well up with fur, which she pulled from off her body and sides with her mouth. They have a very singular way of chewing their cud, if it may be so called, *for they receive their own dung into their mouth and eat it.*" This seems a strange account!

RABBIT SHOOTING. See SHOOTING.

RACE COURSE. The form and length of a race course (says Darvill) must depend on the space of ground the neighbourhood may afford; generally speaking, our country courses are most of them round. As four mile heats are not so much run now as they formerly were, a well formed two mile course, or a round course of this length is quite sufficient. In running for most plates, the starting post is also the winning post. This gives the spectators an opportunity of seeing, from the stand, the starting, as well as the coming in, of the horses, and this, at some of our great country meetings, is as much an object of amusement to them, as the running is of interest and consequence to the men of business. At Newmarket, where they do not run heats, and where they seldom run long lengths, most of the courses are straight, or nearly so, which renders them much less difficult to run over, than a round course, both for the horses and jockeys. All the horses trained at Newmarket, stand in or adjacent to the town, which is a great advantage, for, it is a well known fact, that horses give their races more kindly in running to their stables, than in running from them.

But with respect to the making of

race courses, they are sometimes made in the form of the figure 8, or of any other figure that may be convenient, of from one mile to four; fortunately, however, a course not exceeding a mile in extent is not very frequently met with. There are too many turns in a round course of this length. A long striding horse running on such a course is too frequently turning, or if the turns are but few, they are mostly difficult for such a horse to make at his best pace. The little or middle sized hearty horse, that is a pretty round goer, has a short but quick stride, gives his race kindly, is easily held, and is ready at his turns, is the sort of horse most likely to come first on such a course. Indeed, a large, long striding horse, and more particularly a free runner, cannot be got to run in his best form, with safety, round so small an extent of ground as a mile. The owner would be a bad judge who would bring his horse to post to run on so small a course.

In making a two mile round course, the first thing to be considered, after having surveyed the ground, is, whether the horses shall have to run to the right hand or to the left. This will depend on the most advantageous way the ground can be chosen. Should there be a very steep piece of ground, in any part of it, and more particularly should it be in that

part where strong running might likely be made, or, where perhaps with some horses it were proper to be made, to run up such ground would be preferable to running down it, and it would be giving an equal chance to different descriptions of horses; for the greatest part of the ground of a two mile course is mostly flat, which, when not too deep, is an advantage to the long striding horse; but if there is a pretty good hill in it to ascend, the little close made horse, if he has good action, can generally climb it the best; and if, by making a course to run to the left hand, we avoid running down a very steep hill, it would be preferable to have it go in the above direction.

I have already observed with regard to running over a two mile course, that the post the horses start from, is also the winning post; but in order to decide correctly the coming in of the horses, a second post is necessary, and this must be placed immediately opposite, or in a parallel line with, that behind which the judge stands, as one of the principal objects in placing this post here, is its being a fixed point to enable the judge to decide accurately on the smallest part of the horse's head, which may first appear in a line with these two posts. The post I have here mentioned may be called the starting, the winning, or the weighing post; as on a two mile course it answers all these purposes. It is to be observed, that in fixing the above two posts, they are to be so situated on the course, as to divide the best part of the ground into two portions, one of these portions of ground is for the start, the other, which is of far more importance, is for the horses to run in upon. This part of the course should be straight and level; if it deviates at all from the latter, it should be in a gradual ascent to the winning post. The whole of the posts for marking out the ground should be painted white, and must be placed at such convenient distance one from the other, as to admit of each being easily seen by the jockeys in the running; and to prevent them from getting too close to the large posts, the better way is to bank them up from a pretty wide basis, for three or four feet,—such post should be marked accordingly on the top part; for example, when shorter lengths than two miles are to be run.

Supposing the course I am now arranging to run to the right hand, and that there may be rather a difficult turn to

make in it. Instead of such a turn being made by the jockeys laying a little out of their ground sufficiently early for the purpose of making it, as was formerly the practice, and which was not only dangerous, but has often been the cause of disputes on the subject of foul riding, I would recommend the adoption of the following plan, which would not only prevent accidents, but every thing unpleasant which may occur in running for the turn in the old way. The turn had better be made by an additional number of sight posts, which should be placed wide of such turn, sufficiently early so as gradually to form and enlarge the sweep, the whole of the way round, as much as possible. Making a turn in this way will not only be much safer, and prevent disputes, but it will be giving a more equal chance to the very light weights, who are many of them boys, and who are not so experienced in running for a sharp turn, as some of the older jockeys. An experienced jockey, coming well placed to a turn, and having the whip hand, would not, perhaps, feel much delicacy, when in running for it, to lay a young inexperienced jockey boy a little out of his ground here, the old one knowing that half a length got here, is worth two or three in straight running.

I believe, on all courses, there is generally plenty of room for any reasonable number of horses to run abreast; but in the running between the rails, as we here form the breadth ourselves, we should take care to have a clear space between them of twenty-five yards. These rails on each side of the course, should commence at least a quarter of a mile below the winning post, and should be continued two or three hundred yards beyond it. Indeed, the further the rails are continued on all courses, the better.

At such racing meetings as are numerously attended by spectators, there is generally a space of ground of about ten or a dozen yards in width, and about one hundred or two in length, railed in on the right and left of the course for people on foot. This is a very good plan, as it protects them from the horsemen and carriages. In coming in on the right of the course, there should be two distance posts; the first of these posts is to be erected two hundred and forty yards from the winning-post—the second, a hundred and twenty from it. The first of these posts is the distance-post, when the horses are running four miles; the

second, when they are running two miles.

Attached close to, and in the rear of, the winning-post, should be a small wooden stand, erected for the judge to stand in to decide which horse comes first in the race. There should be to each of the distance-posts a similar but a more temporary sort of stand. Each of these temporary stands may be made by putting two posts at a suitable distance in the rear of each distance-post, with a piece of board in the centre; but this board, at each of these posts, should be two or three feet higher than the floor of the judge's stand, so that the man in the distance stand may clearly see the winning-post, and be ready to drop the distance-flag immediately with that at the winning-post.

The stand, or as it is sometimes called, the grand stand, which is erected for the accommodation of the spectators, is generally placed on the right of the course. The under part may be conveniently arranged for the vending of refreshments. It should be built at a distance of from twenty to five and twenty yards in the rear of the rails of the course. The end of this stand need not be in a direct line with the winning-post, but may come within about ten yards of it. The height and dimensions of such stand must, of course, depend very much on the extent or importance of the meeting held in the neighbourhood. Close up to, and in a parallel line with, the rails of the course, and opposite the centre of the grand stand, should be erected a small round building, eighteen feet in circumference, clear of the walls, which should be eighteen feet high. This building being divided by a floor in its centre, the lower part is for a weighing-house (the door of which should face the stand), the upper part is for a stand for the stewards, for whose convenience a communication may be made by a stair case out of the weighing-house, and on the roof there should be a bell to ring for saddling. In the centre of the weighing-house, the scales and weights should be placed. It is the case, at most of our principal meetings, and it should be so at all of them, that one scale should be made in the form of a chair, and suspended the same height from the ground, as the seat of a chair would be, with a half back, made round in the form of an arm-chair; and an iron triangle of proper dimensions should be fixed to the end of the beam, for the pur-

pose of keeping the ropes that are attached to the beam sufficiently extended at the top so as not to interfere with the jockey's head when he is weighing. This would be much more convenient, as he could more readily sit down in this scale, take his saddle and trusses in his lap, and weigh with more dispatch, and with less difficulty, than with scales put up in the common way. There should be seats round the walls of this weighing-house, and pegs for the jockeys to hang their clothes on. Cupboards would also be convenient here, to hold the trusses and small weights, as occasion may require; for there are many jockeys, at several of our country meetings, who are employed to ride for a variety of masters, and sometimes different races for their first or principal masters, which obliges them to vary their weights, and occasionally to shift them from one saddle to another. When the weights do not run high, and a jockey can come to the weight himself, dead weight of course is not wanted. The trusses and small weights, belonging to different trainers, are then left in the care of one of their boys, or any convenient person who may be near at the moment; perhaps they are thrown down in the weighing-house, and are thereby liable to be mislaid or lost; or, not unlikely, some of the shot may be taken out of them. Racing has now become a game of such importance to men of business on the turf, that nothing which regards it should be done in an uncertain, idle, or slovenly manner. These trusses and small weights, when not in use, should therefore be given in charge of the man who attends the scales; by him they should be locked up in cupboards, and he should be made accountable for them to the different persons to whom they may belong.

The space between the weighing-house and the grand stand is to be formed into a yard, enclosed by rails about four feet high. This enclosure should extend ten feet beyond each extremity of the front, observing to leave the gateways in proper positions; that near the judge's stand is for the jockeys to ride their horses through to get to the scales to weigh, and that near the stand, for the horses to pass through in going to the rubbing-house.

By closing the gates here, after the horses are rode into the yard, the people on foot would be prevented from passing in and crowding round the horses, which they are apt to do while the riders are weighing. It may be advisable, at such

meetings as commence early in the spring, or late in the autumn, to cover this yard with a mixture of gravel and sand, which would make it more firm and dry to walk on, in case of much wet. The ground thus fenced in, I shall call the weighing-yard, into which none should be admitted but people of business, such as the stewards of the races, noblemen and gentlemen who own the horses, the trainers, the jockeys, and boys who look after them.

The weighing house and yard being situated and arranged in this way, mistakes cannot possibly happen, if the jockey does but keep on his horse's back after having pulled him up at the conclusion of the heat or race, until he gets to scale, as in going off the course to weigh he must come to, and pass by, the ending or winning post. Indeed it would be unpardonable in a regular jockey to dismount until he has rode his horse past this post in going to the scales. A jockey who is in high practice of riding, is too good a judge to allow such a thing to happen to him, let the scales be placed in whatever situation they may. If he were so unfortunate, through absence of mind, as to commit an error of this kind, I much fear, it would be at the expense of his character; but a gentleman jockey, on a strange course, and who may not have rode many races, may unintentionally fall into an error of this sort, if not directed by the trainer who informs him how he is to proceed when he has pulled up his horse. From want of experience or caution, a gentleman may make this mistake, either by not riding his horse back to the ending post previous to his dismounting to weigh; or, he may, if his orders are not to run for the first heat, pull up within the distance, and if the scales should be placed (as they often are) inside of the winning post, he may, without giving it a thought, ride to them, dismount, and weigh, without even coming to the ending post; he would, consequently, be distanced, but as I have observed, from the way in which the weighing house and the entrance to it is here arranged, nothing of this sort can possibly happen, if the rider will but keep on his horse's back until he gets to the scales.

The ropes which are to be put up across the course, at the commencement of the rails, to shut out people on horseback, who have no business on this part of the course, should be attended by very steady

men, who are to take care to be ready to remove the ropes at the time of the horses' starting and coming in.

After the meetings are over, it will be necessary to have chains put up here, and secured by locks, to prevent horses and carts from going over this part of the ground.

If the ground be diversified with ascents and descents at moderate intervals in a course of two or four miles, I think it rather an advantage, as it gives an equal chance to the little stout horse as to the large very long striding horse. Generally speaking, they all give their races more kindly over such ground, than they would do in running a similar length over a dead flat.

The next thing to notice relative to a course is the rubbing house, or, as it is called by some, the saddling house, being used for both purposes. This building should be erected at a distance of about two or three hundred yards beyond the weighing post. It will here be somewhat out of the noise and bustle of the crowd, and it will be near to where the horses pull up after sweating or running.

The walls of this building should be in height, from the surface of the ground, twelve feet by sixty-four in length, and the space between them, from eighteen to twenty feet. The stalls in this building should be eight feet wide, to give sufficient room to the boys to work on each side of the horses after they have been sweating, and at the time of their being saddled to run. The partitions between the stalls should also be sufficiently high so as to prevent the horses from smelling to each other over them; but there is no necessity for either racks or mangers in any of these stalls. The walls in front of the horses' heads should be boarded, and rings should be fixed there to tie horses up occasionally. Now, as it frequently happens that there are horses from different stables not only going to sweat on the same morning, but most likely at the same time, (as training stables are sometimes at so great a distance from the ground as not to allow of the horses being conveniently scraped at home, and as it would be unpleasant to the trainers for the horses of different stables to scrape at the same time in one rubbing house,) I think the better way would be to divide these eight stalls, by running up a wall in the centre, and thus making two rubbing houses, with four stalls in each, and with doors of the same

dimensions as those in the training stables; and for the admission of plenty of air and light, there should be two large windows in each of these houses, and they should be on the same plan as the lower part of those windows in the training stables.

In the front of this building there should be a piece of ground twelve feet in breadth by the length of the building, walled in to the height of four feet and a half, with rings placed at proper intervals in the walls, for the trainers and riders to tie up their hacks while the horses are being scraped or saddled. The door is to be in the centre of this yard, and to be five feet in width.

**RACE HORSE.** A horse bred for the turf, or, in other words, calculated for speed. Mr. John Lawrence contends for "the necessity, or at least the utility, of a reserve of thorough-bred horses in this country, on the ground, that, were the species neglected, and suffered to be indiscriminately blended amongst the whole genus, the English saddle horse would, in all probability, become retrograde in quality, and in the course of time would degenerate into the round buttock, gummy carcase, and coarse head, of former days." In fact, examples enough of this degeneracy are always to be seen, he says, in the studs of the different breeders; neither is the number of well-shaped, half-bred stallions considerable, or even sufficient for the demand of the country. In opposition to the idea which some entertain of the propriety of putting an end to horse racing by law, "On the course only (says he) can the worth of this peculiar species of the horse be essayed; and independent of that object, it is scarcely probable that the breed would be kept distinct, or that any very minute attention would be bestowed upon pedigree. It is well known, that not only have varieties of a genus of animals been often blended and lost by neglect, but even arts, and different branches of knowledge, have perished in the same way. From the discontinuance of horse racing, the English thorough-bred horse, the source of almost all that is excellent in the species, might become extinct. Thus the turf is a grand national object, and its votaries are administering, through the medium of their pleasures, to the interest and prosperity of their country.

The speed and continuance of race horses must necessarily be affected and governed, in certain degrees, by the weight which they have to carry; and, reasoning upon that position, it will be

easily conceived, that if two horses be equally matched in point of speed and strength, and put to their utmost exertion for a considerable distance, the horse which carries the least weight, by even only a single pound, must infallibly have the advantage to a certain degree (however small), and possess the ability of going more swiftly and lasting longer than his antagonist. The swifter the pace, and the longer it is continued, the more in proportion will the horse be affected by the weight he carries. It is said, that, in running four miles, seven pounds make the difference of a distance, or two hundred and forty yards, between horses of equal goodness. Weight is therefore regulated with scientific precision upon the turf, and forms a prime consideration in all sporting transactions. The weights carried by race horses vary from the maximum, twelve stone, to a feather, which means a boy of the lightest weight to be found."

The thorough-bred courser, Mr. Lawrence thinks, in a general point of view, the most useful species of the horse, as being applicable to every purpose; which cannot be asserted of any other species. He defines a thorough-bred horse, or racer, to be originally the produce of Asia or Africa, or of the south of Europe. The chief object in breeding a race horse, he thinks, ought to be truth and symmetry in the cardinal points.

As to the "integrity of his blood," he says, "a true racing pedigree, according to the rule of the present time, ought to prove, under the hand of the breeder, that the horse has descended from ancestors of genuine racing blood, without the intervention of a single bastard cross. If the pedigree be long, it is common to take it for granted that there is blood sufficient, although there be no mare mentioned in it, which has proved her blood by her having actually raced; but usually all the horses are reputed runners, or brothers of such. The greater number of mares which have raced contained in a pedigree, the surer and more valuable, no doubt, it must be, particularly if the last mentioned be specified as a reputed racer, or a natural Arabian or barb. A pedigree of one single descent is held sufficient, when the sire and dam are named as reputed and tried runners: otherwise a short pedigree of three or four descents would not constitute a horse thorough-bred, though it might serve for a hunter.

THE BLACK ARABIAN.

It is yet easy to conceive (he adds) how liable the pedigree of a horse must be both to error and imposition, and that the best proof of true blood must ever consist in performance. Various accidental bastard crosses have occurred in our racing breed, at different periods, chiefly distant ones; and they are frequently easy to distinguish in the figure of the stock, by a critical eye. The far greater part of those horses brought over to this country, under the general appellation of Arabians, have, I believe, never seen Arabia, or else have been of its inferior breed. They are usually purchased in the Levant, Barbary, or the East Indies, by persons totally unacquainted with horses, or, at any rate, with the peculiar purpose for which such horses are designed; hence a number of inferior and half-bred Arabians have been brought over at a useless expense, to deteriorate, instead of amending, our racing breed, and to bring Arabian blood into disrepute.

Fine and delicate horses, the natives of warm climes, excel in swiftness; the most perfect of these were originally found in Arabia; but they are improvable in their descendants by a more fruitful country. The Arabians tried in England have never proved themselves, in any respect, equal, upon the course, to the English racers, the descendants of their blood. Although the general characteristic of thorough blood is speed, yet the true test is not speed, but continuance; since many common or half-bred horses have been known to possess racing speed, but no instance has ever occurred of its continuance in those beyond perhaps half a mile: the powers of continuance increase in proportion to the quantity of blood; thus three-part bred horses will persevere longer than half-bred, and those got by bred horses out of three-part bred mares will sometimes equal the real racers. Although, amongst horses equally well bred, superior external conformation will generally prevail in the race, yet racing can in no sort be said absolutely to depend on good shape; it depends entirely on blood: for example, take the worst shaped true-bred horse you can find, and the best shaped common horse; let the latter have a fine coat, loose thrapple, high and declined shoulder, length, speed, in fine, all the admired points of the racer (and such common horses are occasionally to be found); let them run four miles, and the bred horse, although out-footed at first, shall always win the race. This principle is so universal, that perhaps it would be altogether

impracticable to find a thorough-bred horse in England sufficiently bad to be beat four miles by the speediest and best common-bred hack. All bred horses cannot race, many of the highest blood having neither the gift of speed nor continuance; many are defective in the material points of conformation, as it happens in common horses.

The usual trial of speed in English racing, is the distance of a single mile; of continuance, stoutness, or bottom, four miles. It has been asserted with confidence, but not proved, that flying Childers ran a mile over Newmarket in the space of a minute; a velocity so immense, that it turns one's ideas to speed in the abstract, or ubiquity. It has, however, been really performed in a few seconds over a minute; an instance of which, within my present recollection, is that of Firetail and Pumpkin.

The distance of four miles was ran by Childers, in 1721, carrying nine stone two pounds, in the space of six minutes forty-eight seconds. This wonderful animal leaped ten yards with his rider, upon level ground; and is supposed to have covered, at every stride, a space of twenty-five feet, which is more than forty-nine in a second. Bay Malton ran four miles over York, in 1763, in seven minutes forty-three seconds and a half. Eclipse ran the same distance over York, in eight minutes, with twelve stone.

After all, what is the cause or basis of that superior speed, endurance, and strength, which distinguish the southern horse? Doubtless a peculiar innate quality of body, which some attribute to the dry and elastic air of those countries where he is bred, but which appears to me not altogether satisfactory. The game, or wild animals of northern climes possess the peculiar qualities of the race-horse, which they lose in a few generations, on being domesticated; their bones becoming soft and spongy, like those of tame animals in general. The race horse is much stronger than the cart or common horse, weight for weight; his substance being of a more solid texture.

We quote the following from Mr. Hind's late publication of Osmer.

"The formation which I conceive necessary to constitute a capital and perfect race horse, does not relate solely to the proportion and symmetry of the whole animal, taken at a glance, although it be a necessary ingredient to perseverance or *bottom* in the individual so formed; but this formation, to be complete, extends

also to the limbs and joints, by which his motions are performed, and his speed is accelerated or retarded; which depends on the particular manner of the limbs being set on—much more than is generally supposed. Yet have most, or all, those things hitherto passed unobserved, or remained unattended to by the generality of sportsmen.

The race horse should be broad, deep, and have great declivity in his shoulders; his quarters should be long and straight; his thighs should be let down very low; his hock should be distinct, far behind, and from him; thence, downwards to the next joint, he should be very short, which part of the leg should not be strait, but stand under him, like an ostrich's leg, with a long, lax, bending pastern; and these, I think, are, in part, the springs of action: such as we perceive in the ostrich, a very speedy bird afoot. But these are not the only requisites necessary to the formation of a perfect race horse; there being as much difference, and as great a nicety required, in the manner of setting on a horse's arm,—which should be at the extreme point of the shoulder bone, as in any part belonging to him, and which contributes as much to the act of extension, or stretch, as does the declivity in the shoulders. Neither is one horse in fifty properly formed at the knee, for racing; nor does one in a hundred of any sort bear a true proportion from the knee to the fetlock-joint, although it be so very material with respect to every action he is to perform.

By the true position of these joints and limbs, the horse is enabled to cover more ground than one that is otherwise formed, even though the length of body be the same in both; and, by describing so much a greater circle, in going, he is enabled, when he extends himself to the full stretch, to acquire a greater purchase of ground than the horse which stands in a more upright position, even though the latter be the longest of the two.

The proper formation of some of the outward acting parts having been described, let us now consider what else is required to make a perfect race horse?—and I answer, a general proportion, length, muscular substance, and a certain elegance of texture, and of the constituent parts of the whole; the nature of which elegance, or what I mean by it is briefly this:—Supposing the condition of two horses to be alike, in all respects, they will always excel each other, according to the particular elegance and formation of those

acting parts, degrees of proportion, of length, and of muscular substance: the want or the possession of either whereof will not only produce their effect in all horses, but a difference also in the very same horses, when tried together on different kinds of ground. And this result of such trials could not be otherwise, I think; for, if a different formation of the parts, &c. and the degrees thereof, be not the cause of difference in the performances, why then, one of these horses of the right and true blood would act alike on all ground whatever, and be just as good, though made like a hog, or without joints: unless some other cause of action in horses can be shewn, beside this virtue of the blood, or the formation of the parts, &c.

The difference in the requisites just named will also account why some very plain horses, that are not well made to please the eye, and so are called “ill-shaped ones,” shall, by reason of a greater length and depth, and a peculiar manner of setting on the acting parts, (*i. e.* the shoulders, as was remarkably the case with Eclipse,) excel others, which, with the same elegance, possess a greater share of muscular substance and proportion, a more noble and lofty forehead, and a finer figure throughout the whole.\* Thus, the handsomest and most elegant horse in the world, and of true proportion, too, which wants the proper declivity, length, and gift of circular extension, in those acting parts, may turn out no racer at all.

Again, horses with the same elegance, and a tolerable formation of those acting parts, shall be able, by superiority of muscular substance, and a more general proportion, to excel those which have a little more length and depth in the acting parts; for, by means of this substance and proportion, they will bear to be pressed longer than those who are deficient therein; and so far the old proverb, namely, that all shapes run if of the true blood, may be allowed to be true enough. By way of illustration, the reader is referred to the annexed portrait of that celebrated horse Lottery, whose beautiful, we had almost said perfect, symmetry is generally allowed. Lottery's running at Doncaster, (then called Tinker,) for the Great St. Leger, in 1823, will long be remembered; especially when coupled with his after exploits, particularly his contest with Longwaist, for the Doncaster Cup, in 1825.

\* If the forehead be more lofty than the croup, he cannot run well: but, if a strong one, may make a good stager.

When I talk of length and extent in the acting parts, I desire not to be misunderstood, for no horse's legs can be too short.

*Greyhound shape.*—Now, where is he, who will take upon him to say, that some men are not able to distinguish by the eye this difference of formation betwixt some horses, as well as others can distinguish this same difference betwixt some dogs; though perhaps not quite so readily, because the human eye cannot take in, at one view, the parts and proportion of a being, where one is so much larger than the other. For, whose eye does not inform him, that a greyhound will beat a cur-dog, or that a bred-horse (as it is called) will beat a cart-horse? then, why not allow, that there is a difference betwixt two bred-horses; for he who does not perceive, that many such do differ greatly from each other, I am inclined to think, cannot see at all. Is it not evidence that, although many sorts of dogs are as long as the greyhound, every eye may see that one will excel the other in speed, and that mainly from the curves and segments of circles, which one describes in his shape, and which the other has only in a less degree?

Fine greyhounds have, like fine horses, a general proportion, a certain elegance of parts, of length, and are furnished with long-fibred muscles; their hocks are let down almost to the ground behind, and stand from them; and then, to remedy the want of a long pastern, their feet or toes are made longer than any other dogs' that can be named. It is this very conformation, so obvious in the greyhound, and in some horses, which have wide haunches, that in part produces the effect of speed; and the reason why it is not so manifest to all men in both species, is, because the degrees of this formation do not come so near together in dogs as in horses—that of the greyhound far excelling all others of his kind.

Now, the fine greyhound being remarkably broad, and expanded in the muscles of his thighs, I call this a perfection in him; and so I think it is in horses, though it be but seldom seen. This the generality of sportsmen esteem a fault, and what almost moves my laughter, they call it *a coach quarter*.—So little likelihood is there of any agreement amongst mankind about the proper formation of a race horse, that they have not so much as agreed upon the names whereby to distinguish the different parts thereof, even,

although the muscular expansions ought to be very different in these parts, when we require a faultless horse of any sort.

Hares are made in the same manner, and they can describe a greater circle, and acquire more ground at one stroke than any animal known in the whole world, of their size and length; and that because their quarters are so long, their thighs are so much let down, and the lower part of their hinder legs are placed (as it were) under them, and, to answer the purpose of a long pastern, their toes are made very long. From these causes, I am inclined to think, her springs of action are in part derived—add to this, the blade-bone of no animal runs away into her back with so much declivity as a hare's, and this, I think, enables her to point forward. Again, mark the length from the elbow to the knee of a hare, and the short space there is betwixt that and the next joint; by this length of the arm, and the muscles thereof, she can farther extend her foreparts. So it is in a greyhound, though not, I think, to such a degree; and this formation, in degree, so far appertains to the running horse, that he cannot be called perfect without it, let him be ever so well constituted in every other respect. But the degree of shortness, in this part of the horse, is better considered by the proportion it bears to his other parts, than by any general rule that can be laid down.

Now, it is well known among coursers, that the hare can strike as far at a stroke as the greyhound dog, which is so much longer;—tell me then, are her motions performed by the peculiar formation of the acting parts, and the strength and elegance of her muscles, or by any innate quality, and unknown virtue; or whether, from a similarity in these points, found in all animals that are particularly endowed with speed, there may not be some reason to suppose, that the cause of it is the same in each? and whether it be not highly probable, that the Power who created all animals, has ordained, that the different degrees of speed in different horses, should depend on the very same law as the different degrees of speed in different dogs—I mean the law of their constituent parts, even though you and I should happen not to perceive any difference in such parts?

*Of bony horses.*—I have often been surprised, and diverted too, with the commendations I have heard sportsmen bestow on horses, for having large bones;

because I think that, on the contrary, depends, in great measure, the excellence we find in what are called stud-bred horses. If, by this expression, substance only was to be understood, it would be quite agreeable to my notion; but what constitutes the great difference (formation of the acting parts excepted) between the Arabian horses, and all others, is, that some of them have, and all should have, to be perfect, larger tendons, or sinews,\* and smaller bones, than any other horses not made for speed; for these tendons, muscles, or sinews, happen to be the sole powers of acting in all animals, the bones being the weight to be lifted, and serve only to extend the parts.

Which, let me ask, will act with most velocity, and most perseverance for a time, (all other parts agreeing,) the horse that has a large sinew, and a small solid bone, like ivory, *i. e.* like a stag's bone, or he that has a large bone of a soft spongy kind, with a smaller sinew? for the dimensions of the leg shall, if you please, be the same in both—I should think the former. This solid bone, with a firm sinew, and a fine skin super-induced, where you may see every vein, and can lay your finger nearly between the bone and the sinew, shew that the horse has no thick fleshy muscle intervening, which serves only to retard his speed, and is (like the bone) a dead weight to be carried along with it, and which no way conduces to the strength of the animal.

*Limbs proportioned.*—Now, this is what I call elegance of parts, which is not confined to the outward texture only, but extends also to the internal constituent parts of the legs; namely, to the bones, sinews, and membranes, which is in part explained already—and to all the ligaments of the joints—and this elegance of the constituent parts shews itself particularly in many horses, where, though the leg shall have a very sufficient substance, and bear a true proportion to the other parts of the body, yet the pastern shall be very lax, as well as very small, both which are very necessary for a perfect race horse, length and laxness serving as springs for the acquisition of ground, smallness contributing to agility, and to perseverance or bottom.

That the smallness of the pastern shall

---

\* That is to say, large in proportion to the bones the animal has to propel along; but not large muscle that obscures the sinew and conceals the bones.

contribute to the stoutness or bottom of the horse, you will say is very strange, and new doctrine, it being generally looked upon as a sign of weakness. This perverseness I cannot help: but, if there were no other argument to support this doctrine, examples enough of horses so made, that were excellent racers, might be brought in defence of it, and I think no body will dispute matters of fact; though I am not quite sure of that. For instance, Cartouch was a remarkable horse, in these respects, which, although but a galloway in size, beat some good sized horses very easily, all carrying eleven stone!

*Back sinews.*—To explain this doctrine about the smallness of the pastern, as it relates to bottom, we must examine a little the constituent parts of the limbs. To this end, the reader must understand, that in every animal all the difference there is betwixt muscle and sinew is, that the fibres of the first are broad and fleshy, those of the latter, dense, more firm, and drawn into closer contact; whereby the strength of a small sinew becomes greater than the strength of a large piece of flesh (as we vulgarly term muscle, until by hand rubbing, by exercise, hardening the system, and keeping down flesh generally, we convert a great portion of this muscle into sinew). For instance, reader, let us consider, your leg and mine: the hinder part of it, upwards, at the calf, is a fleshy substance, which anatomists have agreed to call muscle; lower down, towards the extremities, this is most compact, and becomes tendinous or sinewy, though it still be a continuance of the same body; and we find it in action capable of bearing its share of work without complaining; whereas, the calves of the legs often do tire and become painful after much walking, or any violent exercise.

Further, I pray you tell me, whether you ever thought a man, who was well formed in all other respects, to have less agility, or less strength, because the small of his leg was very delicate and slender? or, if your leg and mine had been covered with a thick coarse membrane, and composed of loose fleshy fibres, continued down to the extremities, instead of being fine and tendinous, whether you do not think, that such a weight would have been against us, have made us less active, and liable to tire sooner? Just so it is with the horse. But it too frequently happens, when the wise designs of nature

are not fathomed by our shallow capacities, we arraign the skill of the Omniscient Power, and foolishly presume to censure his works, when they are most perfect! *In these things alone, I mean the nature and elegance of their constituent parts, and the due formation thereof, consist the difference between horses of the same and different countries, or betwixt blood and no blood.*

*Speed not heritable.*—Now, ask the sportsman how it happens, that some of these long pasterned horses perform so notably; he has his answer ready, “why, ’tis in the *blood*, to be sure, or else these weak cat-legged devils could not run so.” These same sportsmen have another saying, “such a horse shews a great deal of blood”—(that is to say, shews that he has blood *affinity* to the right breed of horses for running).—Surely they think it something mechanical, and visible to the eye, else they could not use this expression; or, do they pretend to discover, by innate knowledge, the innate virtues of the animal? But they mean, if they mean any thing, what I do, when I say such a horse has a peculiar elegance in the texture of the external parts, (which he derives from his Arabian ancestry.)

But Arabian horses, of the very same family, differ as much from each other, both with respect to length, substance, proportion, elegance, and formation of parts, as horses of the same family can do in other countries; and how should it be otherwise? for we plainly perceive here at home, that there often is a great difference betwixt two full brothers, of all kinds or species of animals: pray now tell me, why this should not happen in Arabia as well as in England? For instance, Conqueror and Othello were two full brothers, but one was a king and the other a beggar, with respect both to form and action.\* If then the difference in the performance of these brothers did not depend on their different formation of parts, &c. pray tell me, on what did it depend? for the cause of it could not be in the blood, unless you will say this innate quality may appertain to one brother, and not to another; and then, I apprehend, the by-standers will say, you have proved it to be plainly nothing.

\* Got by Crab out of Miss Slamerkin; but nine years elapsed between the getting of the two colts, Conqueror being the youngest of the twain; and the same colour as his sire, viz. grey.

A hundred examples of the same kind, and that almost in every family amongst our racing horses, might be brought to show, that two equal brothers are hardly ever produced; and when a difference does happen, it will be just the same thing in its consequences (if the formation of parts, &c. be at all concerned in action) whether it happen to an Arabian horse or any other. Why this difference should be betwixt two full brothers is not at all material for us to know; it is sufficient for my purpose that it does happen: it may arise perhaps from a dissimilitude of parts in the horse and mare, or from a similitude of some parts tending to some extreme in both; it may arise also from some violence or impression on the womb, whilst the foetus is in a soft state, or from some defect of constitution in the mare, or the seed of the horse.

If I could have a horse formed in the manner, and with all the advantages, I have here named, I should be proud to use him as a stallion, were I a breeder, without making any inquiry after his family or country. But, shall the brother of this horse, because he is brought from the mountains of Arabia, and of the very best reputed high blood (as it is called), who is deficient in all or most of these respects, (no matter from what cause,) induce me to breed from him, for the sake of his family and his country only? and that a great difference does occasionally happen in the same, and in every family of horses, I suppose, no man will deny. But it is said with great truth, that the virtue of the blood in him that was no racer, may produce a racing son; to this I agree, it may, when the son has happened to acquire a formation of parts, &c. different from the father’s, by the help of his mother’s constitution. In that case, indeed, an ill-formed horse, that could not run himself, may, and often does, beget a better racer than himself, by the assistance of better parts derived from, and similar to those of, the dam.

On this point, Virgil observed, eighteen centuries ago, that your good judges of breeding require a stallion that is a good runner himself, as well as of true courage, or else the country he is brought from is of little consequence, nor even his lineage, although he may derive it from the immortal gods.

It is owing to this opinion of the virtue of the blood, and what the sportsmen call a proper cross, coupled with an entire inattention to, and want of knowledge

amongst the breeders, as to the laws of nature, and proper conformity of the several parts, necessary to make a race horse, that so very few good ones are occasionally to be found in this kingdom. For, is it not a truth to be seen every day, that the very best reputed bred horses and mares in the kingdom cannot run at all? yet they still serve to breed from for the sake of the blood, or the cross. As to the mares in general, we seldom know any thing of them but their pedigree; yet we talk of the goodness and badness of stallions, as if the mare had no concern in the quality of the produce; and what is worse than this, most men who keep a stud, generally entertain a good opinion of their own mares; so, when these do not produce good colts, they as generally impute the fault to the horse who got them: from such prejudices, some of our best horses often fall into unmerited disesteem as stallions.

But, for the sake of argument, it shall be allowed, that the excellence of horses consists in being of the true blood; what then? is it of any use to the breeder, when experience shews it will not hold good in two full brothers? But he cannot, with common sense, believe, nor have any reason to suppose, that the virtue of that high blood or spirit, call it what you please, which was of no effect in the father, and which would not entitle him to be a racer, should produce a better effect in the son, when this virtue is considered in the light the sportsmen use it (that is) independently of form and matter.

These observations, which I have made on the different families of race horses, and betwixt those of the same family, have made me conclude, that neither the virtue of the blood, or spirit, breed, pedigree, nor proper crossing, will enable one of them to race, unless he has the proper formation along with it.

The difference betwixt the Arabian horses, and all others, consists in nothing else, but a peculiar elegance and formation of parts, and in having a greater share of muscular power; that is, the fibres of these muscles being drawn into closer contact, animals are thereby enabled to move quicker, and with more force, by reason of their membranes and teguments being composed of a firmer and less bulky substance, and their bones being smaller, of more solidity, and occupying less space, they are and can be more easily acted upon by such tendinous or muscular force; and that for a greater duration of time,

with less fatigue to these acting powers. Then, consciousness hereof gives them courage.

*Of Wind.*—In the next place, it may be asked, what gives wind to horses, and whether the causes of that too are discoverable by the eye? To this I answer, that clear wind, or long windedness, depends on the very same principles in all horses, and in all other animals, as agility of action, and ability of perseverance; namely, the nature of their constituent or component parts, particular diseases in these animals not coming into the question; for elegance of parts is no other than wind, and strength, and agility, at least it is productive of them. And, as the elegance of the external texture in the horse is a certain standard or test of a similar elegance throughout the whole internal contexture, so far the cause of thorough-windedness, as it is called, may be said to be distinguishable to the eye.

For instance, the stud-bred horse will gallop twelve miles within the hour, without the least fatigue, or being at all blown, but the cart horse with such a jaunt is fatigued, and tired, and choaked; the reason whereof, I think, is obvious to every man, namely, because his eye enables him to perceive, that one, from the nature and difference of the component parts, acts with ease and facility to himself, and the other does not.

Now, may not the man be thought mad, who says, the difference in the facility of respiration betwixt these horses, depends in one upon form and matter, and in the other not so? and is not he equally absurd, who says, that the difference of wind, in two bred horses of different families, does not depend on form and matter also in both, because the degrees of elegance in the component parts of these two are not obvious to his eye, as they are betwixt the bred horse and the cart horse. For, if we could suppose two horses to be alike in health and condition, and formed and constituted alike in other respects, he that has the most capacious thorax or cavity of chest, will undoubtedly have the best wind; and this is confirmed by actual occurrences, and notorious matter of fact, and would be known to all men, if they were not blindly partial in their observation of things and events.

If a horse has superior stretch, he does not tax his lungs so highly—does not put them to so much labour, as another with finer lungs (larger), but whose fatigue at going a quick pace occasions

greater working of the frame, and its contents, the lungs particularly.

If to this it is objected, that many running horses, with the chest less ample, have occasionally excelled others, with a more capacious one, I allow it is very true, but insist, at the same time, that it is easily accounted for, without appealing to hidden causes. For example, one horse of a less ample chest, with great length and extent in his acting parts, is to contend with another much shorter in these respects, of a more ample chest; but the organs of respiration may be more fatigued in the last than in the first, because the long horse, who goes within his rate, may act with ease and facility to himself, whilst the short one, which is forced to go at the top of his speed, and yet not able to keep company with the other, is of course distressed and fatigued in every part.

For the reasons here given, the Arabian horses and their descendants, when properly chosen, are preferable to all others, whether you are to be carried a mile or a thousand, either for pleasure, expedition, or safety, let the weight be what it will, nor have any other horses such true courage, or calmness of temper, nor can they bear fatigue with equal fortitude, as our severe discipline of training will in some measure help to shew. Not only are they best for riding, but for drawing also, if you breed them to size, and inure them to it early, as it is the custom to do with our English horses that are designed for drawing; for our country horses, whose acting powers, or sinews, are oppressed with coarse fleshy membrane, thick teguments, and large spongy bones, will on this account be much sooner fatigued and tired with their own weight, than the Arabians, even though their acting powers were equal in strength to the Arabian horses, which they by no means are, and that from a difference in the contexture of the muscular and tendinous fibres before noticed.

Just so it is betwixt the southern hounds, and those we make use of to hunt the fox; and yet I have heard the huntsmen talk just as ridiculously of the blood of fox hounds, as if it was something independent of the formation and elegance of their parts, as the sportsmen do about the blood of horses. But in this the skillful huntsman differs from the sportsman, in one respect; for the first very often gives way, or knocks his hound on the head, without trying him at all, if he does

not approve his figure; whereas, the sportsman always trains, if he likes the blood, let the horse be ever so defective in the formation of its parts, &c. But if he would consider his racer merely as a horse, and in the same mechanical light, as he distinguishes his hunter from his cart horse, and would waive this preternatural quality, which he understands by the word blood, it would save him much expense, and many disappointments. For, although the eye of man may perhaps not always determine, with such precision, as for us to say, 'this horse shall make a capital racer,' yet I will be bold to say, that the eye of the same man can most frequently determine with so much certainty, (I mean amongst stud-bred horses) as for him to say, 'this cannot run at all.' But this last assertion will be credited by very few sportsmen; for this plain reason, namely, because the high opinion they entertain of their own judgment will not suffer them to assent to a truth, which they themselves cannot perceive; for all men fancy they understand horses better than all others.

And now, since I am dealing in maxims, give me leave to add one more, which you may depend on for truth, and lay down as a certain criterion of the sportsman's skill in horses, namely, that the more strenuous an advocate he is for this innate virtue, called blood, so much less knowledge he has of the animal, and which opinion of blood undoubtedly is in him, not a tacit, but an open and avowed acknowledgment of his ignorance of proper shape or conformity of parts; else he would not have recourse to occult and hidden causes, to account for facts that are discoverable by the eye. But the word blood, received in its general acceptance, is found to be extremely convenient to such persons; because it is agreeable to the good old law of custom, from which source the generality of men's ideas are derived; and so, of course, it prevents the youthful sportsman the trouble of making any inquiry into the form or nature of horses. Again, they talk just as ridiculously of bad as they do of good blood; for it is a common saying amongst those sportsmen, that they would prefer to breed from a horse, whose blood they liked, though he could not run, rather than from him that could run well, whose blood they do not like, yet both shall be thorough-bred!

Let us suppose a case:—here are two mares, both originally bred from Arabian

horses and mares, or the descendants of such, which I suppose is all that is to be understood by the term 'thorough-bred horses.' One of these mares is called Duchess, and is got by Whitenose, out of Miss Slamerkin; and, because the produce of this horse has been generally found deficient in racing, they are branded with the infamy of bad blood to breed from; yet Duchess herself was an extraordinary racer. The other of these mares was got by the Godolphin Arabian, the best reputed blood in the world, and called Sylvia. Now, she was a very bad racer: then, pray, sir, take your choice, which of these will you have for a brood mare?—why, according to your own doctrine, you must take Sylvia: can the folly and nonsense of this opinion be equal to any thing but the practice of doing it? So, if my horse or mare, which is thorough-bred, and a descendant of Whitenose, Stamperab, or any such, shall, either in the first, second, third, or tenth descent, prove a good racer, (no matter from what cause,) truly, I must be afraid to breed from them, because you, from the prejudices you have conceived, and from not understanding any thing about horses, have been pleased to fix a mark of disgrace upon some one or more of their ancestors!

Now, by way of simile, let us suppose that your grandfather and mine were knock-kneed, crook-legged, and splay-footed—these, I think, would have been but indifferent racers; but will it follow, that such defects must, of necessity, be for ever entailed on all their posterity? Or, don't you think, when any of their issue happen to be better formed, that they would turn out better runners than their splay-footed grandfathers? Mark how the size, strength, activity, shape, and attitude, the beauty and regularity of their limbs and features, the spirit and temper distinguishable in all the families of men are lost, or, perhaps, improved, in one descent! How, in all these respects, this son differs from his father, and that from his grandfather! Pray, now, will it, or will it not, be so with the horse and his posterity, whether you and I have discernment enough to perceive the difference there is betwixt them, or not? But some difference of form must, and will, for ever arise in the breed and posterity of men and horses, and of all other animals, from the different form and constitution of the females, to which they and their descendants are occasionally joined

in copulation, or else the laws of nature are of no account.

Thus, you see, the distinctions set up of good and bad blood, when confined to the descendants of Arabian horses and mares, are equally absurd and foolish; yet, that the best and worst racers are most likely to beget such, cannot at all be doubted, for this is a law of nature not to be slighted.

But this law of nature extends both to horse and mare alike; so that the breeding a good racer requires a thorough knowledge of the animal, and is a matter of judgment, and not of chance, which, by relying solely on the blood, breed, or proper crossing, you make it to be.

Now, it has been allowed, all along, that the Arabians are the best kind of horses we know of, from which it can be expected to breed a racer, or, in other words, the most perfect horse for going; and, that the offspring or descendants of such are most likely to inherit the virtues of their progenitors; as, also, when they are deficient in the proper formation of these acting parts, or lose the elegance or muscular substance of their progenitors, by crossing, or otherwise, they will, according to the degrees of deficiency, in any or all of these points of conformity, fail, also, in the degrees of their performance—which truth we might see verified every day, if we were not blinded by our own prejudices, or took the trouble to understand any thing of the animal.

Furthermore, I am of opinion, that Arabian horses of the same family do, occasionally, differ from each other as much as any horses can do, in any other country of the same family; so that the possession of an Arabian horse, which is wanting in the respects that have been here set down, will be of little service to the owner, let the genealogy, blood, breed, and lineage of such horse be what they may. For these reasons it is I have asserted, and do maintain, that the excellence of all horses depends on their mechanism only.

So, then, there is nothing in blood—indeed, nothing at all—independent of form and matter, as the sportsmen say there is. But the Arabian horses, being better constituted for action, in there several parts, than other horses, do, by means thereof, excel all others, and each other also, according to the degrees of difference which really exists in their form and constituent parts, the nature and application whereof I have here

endeavoured to explain, I hope satisfactorily."

**RACE HORSE, TRAINING THE.**  
 "The training of race horses (says Mr. Lawrence) is now a much more simple and rational process than in former days, and is indeed making a gradual approach to perfection. It was the fashion of old, to stuff horses, under preparation for the course, with many different kinds of baked bread, to load them with an immense burden of clothes, to force them to breathe a suffocating heat within doors, and greatly to overdo them with severe and long-continued exercise. Breads have long since been banished the running stables, where the heaviest oats, and the hardest and sweetest hay, are found to answer completely every purpose of nutrition. Race horses are no longer stifled with heat, like variolous patients under the ancient regimen. The usual length now of the exercise gallop, is from a mile to a mile and a quarter; of the sweat, from four to five miles."

The training of a race horse must, of necessity, be most regular and efficacious, on account of the superior and sudden exertions required of him. Hence the custom of sweating, either once in ten days, weekly, or still oftener, according to the animal's hardness of carcase and proneness to obesity. The method of sweating a race horse, is to load him with a double or triple quantity of clothes, and to run him four or five miles upon the turf, keeping him in general to a long steady gallop, or his rate, but making occasional bursts of speed. After this operation, the horse is taken within doors, and gradually uncovered, whilst the sweat is scraped from all parts of his body with an edged wooden instrument; when, being rubbed perfectly dry, his accustomed clothing is replaced. Sweating is usually performed in the morning.

Mr. Lawrence next describes the familiar life of the race horse. His winter, he says, is usually spent in the paddock and loose stable, enjoying himself at his ease, until the period of physic arrive, which must be so fixed, that there be at least an interval of two months between the last dose and the first race: this interval is of course spent in exercise. The author assumes here, with the majority of persons concerned in training, that no race horse can perform, to the full extent of his natural powers, without having undergone a course of purgatives. The spring and summer are passed in exercise

and racing, the horse perhaps travelling to a number of different courses in the country. A racer travels, perhaps, from twenty to twenty-four miles per day; and this, on the hard road, must of course abate his speed, whence arises the advantage of those which have been trained on the spot where they are intended to run. Mr. Lawrence says, he has also been assured by grooms, that a horse, in the midst of the racing season, when a sufficient interval can be spared, is frequently much benefited by a dose of physic. That the practice admits of great extremes, the following judicious remarks very fully evince.

"The purging system of the running stables (says Mr. Lawrence) is still liable to solid objections. Grooms always fancy that the body of a horse abounds with noxious humours, which require specific purgation. In their ideas, racing and aloetic or mercurial physic are connected by an indissoluble chain; and these nostrums are supposed to operate by a peculiar innate virtue or charm. All this is of much the same weight with any other nonsense which prescription may have sanctioned. The exhibition of physic in this case bears no more relation to the expulsion of evil humours from the body of a horse, than to the extirpation of corns in his feet: the sole intent is the detrusion of accumulated alvine fæces, in better English, unloading the stuffed bowels, attenuating the blood, and refrigerating or cooling the general habit. Against the best aloes no general objection can possibly lie; it is a cathartic, equally mild, safe, and efficacious; but I know of no possible business a groom can have with mercurials, in the case of physicing merely for condition. In some instances, the neutral salts might be substituted even for aloes, with great advantage; I mean with washy, hot, and irritable horses, which soon part with their flesh. If a person accustomed to the stable forms, would not be satisfied that his horse could race, having been purged with Glauber's salts only, let him make the essay with one which he does not intend should run to win.

It appears to me, that race horses are invariably over-purged, either by an excess in the number or strength of the doses, or by the use of Barbadoes aloes, or mercury. Such a cause can never fail of the effect of detracting from a horse's speed, and of debilitating him, however it may possibly elongate his stride. The cords and pulleys of the machine are de-

prived of too much of their spring, in which consists both the edge of speed and the grasp of continuance. The exercise also is, I am convinced, even yet too severe and indiscriminate, and our horses are often brought to the post in a condition much below their work. The external signs of this error are, want of cheerfulness, delicate feeding, refusal of water, or greediness of it, loose testicles, and backwardness in recovery of flesh after training. Many a colt, I believe, is tried and rejected, at the same time, seven or ten pounds the worse over the course, for his exercise and physic."

Mr. Lawrence acknowledges the truth of the common observation, "that a horse cannot run fat;" but insists, at the same time, that a very erroneous use is generally made of the maxim. The material question, he says, is, what is the proportion of physic and exercise calculated for such horses? a question which must be left to the discretion of men of sense and experience. If a horse, after three doses of physic, regular gallops, and a week's sweating, still carry a shew of superfluous substance, Mr. Lawrence would even start him under this disadvantage, rather than attempt to break down the texture of the animal with mercurial purges, or work him off his legs and speed, with extra sweats and violent galloping. "How often (says he) have I heard of horses, which were before ready to devour the manger, sweated out of their appetite, and then, if time could possibly be allowed, to mend the matter, purged with strong mercurial physic. The universal panacea of purgation is resorted to on all occasions."—"The error is still more gross, to over-train horses of naturally weak stamina, and irritable habits; such should always have a due portion of fleshy substance left to support the weak and flagging fibres. I suspect the usual routine of exercise is always too severe for these, but from its being general and common to them all, its ill effects are less apparent. There are horses which become bone lean in two or three weeks' exercise; I would ask, why continue to sweat such, since they appear to have no fatty substance left to sweat away? Washy horses particularly, I believe, get rid of their internal fat first, and, for the sake of their wind, would it not be better to sweat or rather give them a four-miles moderate gallop, in only their ordinary clothes, without any additional weight? which last, to the amount generally laid on, must debilitate

in a very considerable degree. I have seen some of your hot fly-away racers, so excessively influenced by nervous affection, that their lives seemed to be one continued state of anxiety and inquietude. These are always found awake to dreadful expectation: the groom touching their body girth, sets their hearts palpitating; the act of taking down the saddle operates as a cathartic to the imagination, which, from sympathy, is instantaneously followed by visible effects; they well know the sweating day, and the sight of the sweating clothes gives them a fit of the horrors. The secret of training these horses is, I should think, to give them as little work as possible, and that by themselves; to endeavour to render their exercise rather a pleasure than a fatigue and a terror to them; and not to be alarmed at the little extra flesh they may bear, which will surely rather help to carry them through, than retard their course."

The same well informed writer offers some remarks upon an established doctrine of the stables, that half-bred horses will not stand training: "There is no doubt (he says) that full-bred cattle are naturally best adapted to such a purpose; but the inability of the half-bred to endure this discipline arises chiefly from its severity, and the want of its proper adaptation to their natural powers. There is comparative speed and stoutness in every variety of the horse; and Bracken has said, that, by proper training, he could enable even a cart horse to run up to his foot. A remarkable quality in the race horse is, that which is styled, in the language of the turf, *running to the whip*; it means answering every stroke of the whip with an additional exertion, as long as nature lasts. Horses of this generous kind are termed 'honest,' and 'stout:' but the terms are usually confounded; for many a horse is honest, without being endowed with those constitutional powers necessary to produce stoutness or continuance; and many which possess those in the amplest measure, which they occasionally evince, are yet never to be depended upon. It is dangerous to offend these last with the immoderate use of the whip or spur, and I have known a winning horse stopped instantly by a foul cut under his flanks: I have also known, and indeed ridden, horses, honest and stout as the course was long, yet with such indignant stomachs, and such critical skill in their own powers, that, being convinced in a race of the impossibility of success, if abused with the

whip, they would instantly shorten their stroke ; but if nursed, and encouraged with a pull, the use of which every jockey knows, would, although beaten, strain every nerve to the last extremity. It is a strange quality in the true whipped horse, that he seems really to have a penchant for the whip and spur, since he absolutely will not keep to his stroke without the one or other of them, and never takes offence at either."

We copy the following from that useful little work the *Turf Expositor*.

"Training is an indispensable process for the race horse, the perfection of which must consist in bringing the animal to such a state, as to be enabled to use his powers to the best possible advantage. A horse, to be in perfect condition, or completely trained, should carry as much firm elastic muscle as possible, without even (if possible) a particle of fat. I am aware that an ignorant groom would immediately remark upon this, that some horses will carry much more flesh than others ; which is very true ; but my position, on that account, is not in the least affected : and I repeat, that when a horse has got upon his bones (by means hereafter to be noticed,) the greatest possible quantity of firm elastic muscle, destitute, as I before observed, of fat, his condition of training is perfect.

The best means of attaining this highly desirable state constitutes the object of consideration, and forms a subject upon which a diversity of opinions will most likely be found to exist. At the first blush of the case, it is abundantly evident, that it must be accomplished by food, physic, and exercise, the judicious and correct administration of which is the question at issue. Among the generality of persons who follow the occupation of training, the process is a regular, if not a mechanical, system, and, consequently, those constitutional differences which cannot fail to exist, are not sufficiently taken into consideration ; or, I may say, not sufficiently understood : what may be called the dictates of nature are, in a great measure, disregarded. There are delicate horses, and horses of robust constitutions ; and, if preparing these animals for the course, natural causes are not duly considered, they can never acquire the requisite condition to enable them to put forth the most of their powers. And, since horses differing in constitution, feed more or less, according to their temperament, so will they require exercise and physic precisely

in the same manner ; hence, no positive rule can be laid down ; the treatment must mainly depend upon the judgment of the trainer.

I cannot help suspecting that race horses are very often over-trained, and consequently, when brought to the starting post, have suffered some deterioration of powers. Sweating, to the extent to which I have seen it carried, must have an injurious effect on the animal's constitution, and also upon his powers of performance. I will quote what the celebrated Chifney says upon the subject:—

"It is destruction to horses to sweat them in the manner they are sweated at Newmarket, as the practice there is to sweat them once in six days, and sometimes oftener ; and between those days of sweating, it is usual for the horses to go out twice a day, each time having strong exercise. In those sweating days, the horses are mostly covered with clothes, two or three times doubled, and go in their sweats six miles, more or less, and at times go tolerably fast. Directly the horse pulls up, he is hurried into the stable, which is on the spot for the purpose. As soon as he gets in, there is often more clothes thrown upon him, in addition to those he has been sweat in. This is done to make the horse sweat the more, and he stands thus for a time, panting before he is stripped for scraping ; that, with being thus worked, clothed and stoved, it so affects him at times, that he keeps breaking out into fresh sweats, that it pours from him, when scraping, as if water had been thrown on him. Nature cannot bear this. The horse must dwindle.

I think, in the first place, that the horse has been too long at this sort of work for his sinews, then the clothing and stoving forces his juices from him in such quantities as must destroy his spirits, strength, and speed ; and much clothing jades horses. A horse does not meet with his destruction when he runs ; for then he is likely to be lighter in his carcase, lighter in his feet, having plates on, not shoes, which is wonderfully in favour of his sinews ; and he is without clothes, and not stoved, and his course in running is very seldom more than four miles ; therefore, this difference in sweating and running is immense.

When a horse pulls up from his running, he has time given him to move gently in the air, and is usually scraped out upon the turf, and by these means

the horse perspires no more than suits his nature.

Horses should have different brakes against weather, to scrape in. Buildings for this, I think, would be most proper made after the horse dealers' rides in London; open in front, being out of the weather, and not out of the air. Places of this sort would be much better for horses to saddle in; for horses saddling in those close, dark stables, they, at times, break out with great perspiration, when saddling; and, in fine weather, in roomy places of this sort, there would be proper room, &c. for noblemen and gentlemen sportsmen, to command a sight of the horses at saddling; and horses are less timid being in a crowd, than they are to hear it, and not see it.

When a horse is first taken into work, after having had long rest, his carcase is then large and heavy, and the practice is to put more clothes upon the horse, and order him to go a longer sweat. But the horse, in this stage of his training, is the less able to bear more clothes, and go farther in his sweats; for the horse himself being heavy, that, with body and clothes, at times, has a great weight upon his legs; that, with this pressure, and his work heating him, it makes his sinews full and weak; and, thus working a little too fast or too long upon his sinews at one stretch, they are forced out of their places. This once done, the horse seldom stands training after.

It is ignorant cruelty in the great number of horses being thus unskilfully lamed at Newmarket, and gentlemen not only lose the use of their horses and their money by it; but it so greatly deprives them of their sport, that they otherwise would have."

Of late years, training may have, and I think has, experienced considerable improvement; or, at least, the race horse is not subjected to that excessive degree of toil, and even torture, as formerly marked the system; but then, as if to counterbalance one evil, another has been introduced—I mean, training at too early a period. An overgrown colt or filly, particularly the former, will be frequently found unable to stand the early training to which race horses are subjected at the present day; and yet such are often continued in the training stable, though they cannot race, and are almost constantly amiss; till ultimately they are turned out so very unsound, as to be scarcely worth keeping for any purpose. Animals of this

description, particularly if their form be promising, should be again consigned to the paddock, and there remain till they have acquired sufficient strength, in proportion to their size, as will enable them to perform the indispensable labour of training. It may also be further observed, that to irritable and washy horses, the systematic mode of training, and the periodical sweats in particular, must be highly injurious: they seldom carry sufficient flesh; and, as I have already stated, no horse can carry too much flesh or muscle, so long as it is divested of fat.

The ground also upon which race horses are trained is a matter of consideration. Very hard and very wet ground may be said to be equally objectionable, for reasons too obvious to need an explicit enumeration. The best ground for the purpose is that absorbent, elastic turf, which is found in moor lands—in fact, it constitutes what may be called the dry part of the moors: and hence we see the reason why the principal trainers reside in Yorkshire, where the very kind of turf, so desirable for the purpose, is in plenty. Further, it is a prevalent opinion, that horses cannot be well trained on a dead flat; but that they should be exercised on uneven or hilly ground. This, like many other general opinions amongst the unreflecting part of the community, requires qualification, or, at least, a little explanatory elucidation. I had, a few years ago, some conversation with a *knowing* Yorkshire trainer, upon this subject:—the man "*stood well with himself*:"—he dealt out his notions in a mysterious manner, in short and pithy sentences, which he at least considered as oracles of wisdom; and in respect to training upon hilly ground, he remarked that it gave the horse a better stride, opened his chest, and improved his wind!! At the first view of the case, it is evident that galloping upon a hilly surface must be much more distressing to a horse, and place his sinews or tendons in much greater danger:—and, therefore, although the general voice may be in favour of this mode of training, I cannot agree to its unqualified superiority. I shall be told, as I have been, that a horse, trained upon a level, will stand still in the race: but I should be glad to know, who has ever witnessed such a circumstance? I have seen a horse, trained upon what may be called a dead flat, run remarkably well—so much so, indeed, that he started five times the following season, and won every

race! For my own part, were I to choose the ground for training, as far at least as regards the unevenness or otherwise of the ground, I would prefer, not exactly a dead level, but where the surface was in some places gently undulated. The fact is, that a racer should be trained upon ground as similar as possible to that upon which he will have to contend in public; and as race courses vary, but are seldom remarkably hilly, so, it will easily be perceived, that a gently undulated surface is the most likely to be generally applicable to the purpose in question.

The present system of training is to commence operations at four o'clock in the morning, by brushing the horse over: this being done, and the horse having finished his corn, he is taken to exercise; he takes his walking, galloping before and after water, in *time* and *distance*, according to the animal's age, state of his flesh, &c. When he returns to the stable, wispings, leg rubbing, brushing, &c. ensue; afterwards, feeding, and the door is closed, the horse being left to himself, free from all kinds of disturbance: all this is finished as early in the day as possible. A similar ceremony, but shorter, takes place about three hours afterwards. Noon (twelve o'clock) for instance, brushing, feeding, &c. again, and the stable door is again closed for several hours, when similar operations to those of the morning, that is, air, water, and exercise, are repeated; similar stable discipline follows; the door is once more closed, about six o'clock. At the hour of eight, the horses are fed and racked up: thus the race horse is allowed at night to enjoy eight or ten hours with much advantage to the animal: and if the stables were not kept so oppressively hot, as many which I have visited appeared to me, they could not fail to be more conducive to the health of their inmates, who, under such circumstances, must necessarily breathe an atmospheric effluvium which cannot be otherwise than highly injurious to the animal constitution.

The administration of physic ought to depend upon circumstances and the constitution of the horse: it ought to result from the judgment of the trainer; and not given at systematic periods, so much the fashion some years back; and, I fear, not yet entirely exploded.

Chifney, in his "Genius Genuine," observes, "Some few, I am informed, have a way of pinching the race horses in their meat and water. This is another certain

way of perishing a horse in his spirits and strength. When a horse is too large in his carcase, he should be well fed; and, instead of pinching him in his water, where a horse is greedy of it, he should be watered very often, and at all times given as much as he will drink: he will then drink less, and come straight and strong in his carcase."

On the whole, I am of opinion, as I observed in the early part of the present article, that horses are frequently over-trained. However, it is tolerably well known, that under any system of training, horses will vary in their running:—the utmost speed of the race horse must necessarily depend on a variety of circumstances, and he will run variously at different times, and on different occasions.

In looking at horses, bone is regarded as the emblem, or rather as the indicator, of strength; and so it certainly is, but not in the way in which it is unthinkingly understood. Bone is the great support of the frame; and where there is much bone, the tendons will generally be large in proportion, and consequently much more muscle will be found also: hence, where there is much bone, the tendons will be large; and of course, in training, much more muscle can be placed upon them, than where the reverse of this conformation affords no such opportunity."

**RACE HORSE, PLATING THE.**  
Race horses should always be plated before they are brought to post, where it can be done with safety.

The shoeing smiths, who live in a racing neighbourhood, are generally good hands at plating horses, being constantly in the habit of receiving instructions, and as constantly cautioned by training grooms to be careful in fitting the plates, preserving the feet, and driving the nails. It may therefore be advisable to plate such horses as may have good sound feet, and that are standing in stables close to the running ground, the evening prior to their running, after their coming in from exercise. On the morning that a horse is going to run, it is usual to walk him out on the heath, and there let him take a short canter, merely to see if all is right, and if he is well on his feet and legs. If the horse is observed by the groom to go stiff or short, and if the groom is of opinion that this is occasioned by any thing wrong about any of the horse's feet, there will be time to remove the plates, and to give the nails less hold or a different direction. The foot may afterwards be

relaxed in a bucket of water so that the horse may be brought to post, and run without much danger of being lamed, if the ground be not too hard.

Horses that may be heavily engaged, as some of those which may be entered for either of the great stakes, the Derby, or the Oaks, at Epsom, or the St. Leger, at Doncaster, often stand high in public opinion. Under these circumstances, to make all safe, and to satisfy the public, it is usual, and indeed very proper, to bring good shoeing and plating smiths to attend them from the different neighbourhoods where large training establishments are kept. This arrangement cannot well extend to country plate horses that are travelling during the summer from one meeting to the other; and from the repeated necessity there is for removing the shoes and plates of such horses, their feet are frequently in a very broken and weak state on their return to the home stables in autumn.

There are many shoeing smiths in the country who shoe horses very well; but there are many of them who have but little experience in plating horses, and what is worse, as it frequently happens, they have the most difficult feet to put plates upon.

When horses are to be plated, the groom may go himself, or he may send one of the boys to the smith over-night, with directions for him to attend at the stables in the morning, that he may take measure of their feet, and make the plates for such of them as may be going to run on the following day.

If there is any difference to be made between the size of the shoe and that of the plate, it is that the latter should be rather less than the former in its circumference round the foot, so that the plate may, to a certain extent, rest in the bed which may have been formed by the shoe. The plate should not, by any means, project beyond the edge of the hoof; for, should a restless, irritable horse have to saddle on the course, (which is the case where there is no rubbing house) he may, from jumping about, tread a plate off, unless the precaution is taken of setting the plate level with, or within the edge of, the hoof.

Now, as the crust or wall of horses' feet which may have been often plated, is more or less broken, the groom should direct the smith, as he is measuring the feet, to make his observations on the most sound parts of the crust, and as the nail holes of

plates are placed further apart than those of shoes, it sometimes gives the smith the advantage of driving his nails into the more sound parts of the foot. The groom, on such occasions, cannot too strongly point out the necessity of punching the nail holes in such parts of the plate as will immediately correspond with the sound part of the horn, provided those parts are so situated as to admit of the nails being driven into them, and the plate rendered secure without driving the nails too far back from the end of the heels of the plates; or if, to preserve the hoof, the smith can safely drive a nail occasionally into an old hole it may be done.

As plates are narrow, they cannot well come in contact with the sole, so as to occasion pressure there; they may therefore be made flat on both sides. Whether the horse's plates should be made to come home to the heels of his fore-feet, (and which I shall call full plates) will depend on circumstances. I shall first describe how the former should be made. The smith is to observe in the making and fitting of this plate, that the heels of it are to be brought but just up or home to the horse's heels when on, and not to project the least beyond them; and to prevent any hold being taken by the toes of the hind feet, the heels of the fore plates should be bevelled off.

If plates are properly forged, they require little or no rasping, which only renders them weak. Plates for moderate sized horses need scarcely ever exceed in breadth three and a half eighths of an inch. Middle sized, light horses, running short races, and not heats, (more particularly if the ground is soft) may not require them even of that breadth and substance. But for large horses, whose feet are in proportion to their size, the plate should vary accordingly. The fullering or groove, which is made round the centre of the plate, cannot well be too coarse, provided it does not too much weaken the plate. The fullering must be made in the centre, for if it is made to approach too near the outer edge, it will weaken the plate, in which case the smith cannot well get sufficient hold with his nails to keep the plate secure.

The depth of the fullering must be regulated, and the nail holes punched in it, according to the substance of the plate, and the size of the nails which are likely to be used in putting it on; that is to say, that by a smart blow or two from the hammer after the nails are driven, the

heads of them should be buried, and on a level with the surface of the plates.

The situation in which each nail hole should be placed, will depend in a great measure on the size of the plates. In good feet, the nail holes should begin where the toe may be said to end. There should be four nails on each side; the first and second nail holes from the toe may be punched an inch or more apart. Be this as it may, the smith must observe to regulate the distance here between these two holes so as to admit of his punching the third within the distance of about an inch and a half of the end of the heel of the plate; and in the centre of the space there left, between the third nail and the end of the plate, the last hole of the four should be punched; otherwise the plates, particularly of the fore feet, will spring at the heels, from the concussion produced by severe running on hard ground.

Horses that are kept in reserve for particular races, are consequently but seldom running. Their shoes and plates not being often removed, their feet (unless they have been neglected) are sound and strong, with good heels, and plenty of horn to nail to. For such horses, the full plate is to be preferred, as it gives the horse a more firm and level tread with his fore feet than the three quarter plate can possibly do.

The three quarter plate is made in most respects like the full plate, except in its length. Being shorter, it seldom requires for its security more than three nails on each side; and, as in the first-mentioned plate, where the toe ends, the first nail hole should be punched; the divisions being so arranged by the smith, as to the distance from each other, as to admit of the last hole being punched within half an inch of the end of the plate.

A three quarter plate is more generally used for country plate horses, their feet having got out of order from the repeated running and travelling, together with the necessity there is of frequently removing their shoes and plates. The plate must not be made to approach nearer the end of the horse's heels than there is horn sufficiently sound for it to rest upon; and it should also be sufficiently strong at those parts to give the two last nails a firm hold, that the plate may not spring at the heels when the horse is running.

Some horses' feet will allow of a plate of this sort coming within half an inch of the end of the heels; and others may not

allow of its coming within an inch or more. It is the soundness and substance of the horn at the horses' heels and quarters which must regulate the length of the plates.

Country plate horses, if they are good ones and properly selected, are generally of pretty strong constitutions; and when they are sent on a circuit, or what is commonly called, a roving commission, it is with a view to pick up what plates they can; and as the season advances, unless great care is taken of them, their feet, from the causes already mentioned, get into a very indifferent state; so much so, that it is often difficult for even a good smith to put their plates on with safety, and, at the same time, securely.

The hind plates may be made as the fore ones, and may be brought well home to the heels, as the heels of the hind feet are mostly in a good state. If a horse is a long striding one, and a free runner, he is likely to be rather a difficult one at his turns; and although it may be bad judgment to run such a horse over a small round course, yet, if such should happen, it may be advisable for the safety of both the rider and the horse, to give the latter some hold of the ground, by turning up the heels of his hind plates. But with a horse of the middle size, that has a short but quick stride, gives his race kindly, and is handy at his turns, there may be no occasion to turn up the plates. However, an experienced training groom, before his horse is plated, generally puts himself in possession of the sort of course he is going to run over, by previously cantering his hack over it, and he should afterwards regulate the plating of his horse according to circumstances.

The plates being made according to the directions given, the groom must then decide whether they shall be put on in the stable or on the course. This will depend on the distance the former is from the latter, and the sort of feet the horse may have.

Many of our country courses have not a stable near them. On such occasions, the horses are often obliged to stand at stables in the adjoining town, which is sometimes at a very considerable distance, perhaps two or three miles. This is much too long a length for horses to walk in their plates; indeed under almost any circumstances, it is too far unless it be on turf. If there is no other way to the running ground except on the hot surface of a hard turnpike road, I should strongly

recommend the groom to have his horse plated on the course, more particularly if the three quarter plates are to be used.

I shall now make some few remarks on taking the shoes off from race horses' feet preparatory to the putting on of the plates. When the wall or crust of a horse's feet is strong, and there is plenty of horn to nail to, and the soles are of a good substance, the shoes may be taken off in the usual manner, without much risk of injuring the foot. The smith, in taking them off, first knocks up the clinches with his buffer; then, with one side of his pincers placed between the shoe and the sole of the foot, and with the other side of them placed on the outside and upper edge of the shoe, he gives sufficient strength in forcing them downwards and inwards, to draw the nails, and the shoe comes off in the pincers. But with horses that have thin weak feet, this method of taking off the shoes must never be had recourse to. I have observed smiths, who were not much in the habit of taking shoes off from horses' feet, use more strength than judgment. On such occasions, if they would give themselves time for a moment to examine the sort of feet from which they may be going to remove shoes, they would find that to use less of the former and more of the latter, it would not only be considerably safer for the horses, but much more advantageous to themselves; for by doing the thing properly, they would preserve the foot and have more horn to nail to.

In removing shoes from bad feet, the smith should first knock up the clinches with one end of the buffer, and with the other he should start the nails, and then draw them out with the pincers one by one; the shoe would then fall off.

In putting on a race horse's plate, it will be observed that, if the horse's shoes should not have been removed from his feet for the space of three weeks, the hoof will, during that period, have grown, and with the action and weight of the horse, the shoe will in some degree, have imbedded itself into the foot. After the shoe is taken off, nothing should be done to the foot if it can be avoided, as (if the plate is made as I direct) there will be a sort of seat or bed round the crust in which the plate will lie, and this will in some measure, support and assist in keeping it in its place. However, it may sometimes be necessary, after the shoe is off, to run the rasp very lightly round the lower edge of the crust. If the groom

and smith see that it is requisite to remove a very small portion of horn, so as to level the foot that the plate may have an even surface to lie on, it must be done; but this is all that can be wanting. The heels of weak feet should be kept strong, that is to say, nothing should be unnecessarily taken from them.

Little need be said with regard to the nails which are used in putting on plates. The sizes which are in general use, are from No. 4 to No. 6, depending much on the size of the foot and weight of the plates. They should be tough, and of the best quality, and as it is not necessary to drive them very high up in good feet, the shorter they are, in reason, the better; as the clinches will not be so coarse as a long nail, and this is an object worth attending to, more particularly with such horses as have thin crusts. The smith, having carefully sized, straightened, and judiciously pointed his nails, according to the sort of feet he is going to drive them into, next commences putting on the plates. If he takes but common care, there is not much difficulty or danger to be apprehended in the driving the nails into such feet as are strong, sound, and good. But without the greatest care and attention possible on the part of a good smith, difficulty will be encountered, and danger is to be apprehended in driving nails into weak, broken, and unsound feet.

A smith, on putting plates on such feet, must be very careful, and pitch his nails a little in, or out, so as to give the proper direction to each nail in passing it safely either low down or high up through such parts of the wall or crust of the foot. As he approaches towards the quarters and heels, it will be necessary for him to reduce the size of the nails, not only to prevent those parts from being much broken, but to give to each nail here, of whatever size it may be, a safe and secure hold; or, when it is necessary, to get a hold higher up in the foot, and when a common shoeing nail is used for the purpose, the smith should take care in beating out the nail, to draw it rather fine at the point, that in driving it he may not break the upper part of the hoof more than can be avoided.

The nails being driven, the smith gives a smart blow or two with his hammer on the head of each nail, so as to drive it home and bring the head upon a level with the surface of the plates; he then nips off the points with his pincers and

knocks down the clinches. But a smith who may not have been accustomed to plate horses is very likely (unless he is cautioned by the groom) to do in this case as he would in putting on shoes in the common way, which is, before he knocks down the clinches, to make a nick with the edge of his rasp under each clinch, so as to let the clinches into the hoof. This should never be done in plating horses, as it only tends to weaken those parts in the hoof, and more particularly if the crust or wall of the foot should be thin. There is another error into which a smith may fall who is unaccustomed to plate horses, if he is not cautioned. The error to which I allude, is that of his improperly using his rasp in what he calls finishing off the foot, by rasping over almost the whole surface, and thereby weakening the crust. This is not the only disadvantage likely to result from this method, for as the clinches of the nails used for putting on plates are small, the most trifling rub with a rasp may cut through them, or perhaps so much weaken them as to render the plates insecure. If there is any occasion to use the rasp after the plate is put on, it can only be to rub down the head of a common shoeing nail which may project, when the fullering is not sufficiently coarse to let in the head of it.

I will, for example, suppose an instance at a country meeting at which it is the custom to run heats. When a horse has run the first heat, he is pulled up, and rode to the scale for the jockey to weigh; after which, he is led out from the crowd to some convenient place to be rubbed over, and to be got ready for the second heat. This being done, and the horse's clothes put on, the boy who looks after him, takes up his feet, and, if necessary, he picks them out. But there is one thing which the boy knows to be very necessary, and that is to see that his horse's plates are not only on, but that nothing has happened to them; that is to say, he must see that the plate is neither broken nor sprung at the heel. Such things will sometimes occur when the ground is hard, and the plates light, or when they are not nailed close to the end of the heels. If a plate is thrown or broken, a fresh one must be put on. If a plate has sprung at the heel, it must be put right, which it may be sometimes done without taking it off, provided the horse has very strong sound feet. When a plate can be put right

on the feet without removing it, or without any risk of laming the horse, the method of doing it is this:—the smith should place his pincers shut, or nearly so, between the plate and the foot, and giving a gentle blow or two with his hammer on the end or heel of the latter, he brings it straight again; after which, as the foot is strong, he may, in order to prevent the same thing from recurring, take fresh hold higher up, or by making use of a larger sized nail in the same hole, secure the plate. But when a plate may have sprung at the heel of a weak foot, the groom must never allow the smith to put the plate right *on* the foot, or the odds are that the horse will be lamed. The plate must be taken off, and brought in place on any hard level surface that will answer the purpose. To prevent any thing of this sort happening to a horse's plates, the greatest care and attention should be paid by the groom to the making of them, as also to the putting them on, for when it happens that a horse's plates get at all wrong, it sometimes occasions great trouble and delay if the horse be high couraged or impetuous, and more particularly, should he have been called upon rather severely, or perhaps punished a little in running the first heat.

From incessant travelling and running, a horse's feet soon get out of order, unless great care be taken. When they are in that state, the horse must run in three quarter plates, if he has to run long lengths, or heats; and if the ground be hard, his feet will suffer much from concussion, and become very hot and painful.

If the horse, after running, has a long way to walk to his stable, perhaps on a hard road, his plates should be carefully taken off on the course, and his shoes should afterwards be as carefully put on. But when a horse walks from the course to his stable in his plates, I have known some grooms, after having the plates taken off, let the horse stand without shoes. Of this I do not approve. A horse with his feet in the state I have described, cannot well bear the weight of his body on them without shoes; and until the heat and pain in his feet subside, he is mostly seen lying down. I should recommend grooms not to let a horse, under the above circumstances, stand without shoes. It is better by far to put them lightly on, driving the nails into the old holes, and turning down the clinches as easy as possible.

A horse can then bear his weight and will stand or move about in his stall or box with more ease to himself, than when he has no shoes on.

Remedies for the relief of his feet can be much better applied, but not bran poultices, as used to be the custom. These are not good on such occasions, as the weight of the horse when standing spreads them abroad, and the heat of the feet soon absorbs the moisture of the poultice; and they are inconvenient for horses either to stand or lay down in. It was the custom, and a very excellent one, on a horse's arriving at his stable after running, to foment his legs and feet. I should afterwards put wet pads round the crust of the fore feet, and stop the bottoms with wet tow, before the stables are shut up at night. The pads and tow should be fresh wetted every stable hour.

If the horse be a craving one, and is likely to lie by for ten or twelve days, I should recommend a dose of physic to keep him light and to assist in getting his feet cool. As soon as the inflammation and soreness has left his feet, the wet pads should be removed, and the tar ointment occasionally applied round the crust of the feet, always keeping the bottoms constantly stopped with wet tow. This is the treatment I should apply to the feet of horses that may have got out of order from the causes before mentioned. If a horse's feet are weak and his heels low, and he has to run on hard ground, it would be advisable to let him run in his shoes.

A horse that has strong feet may be plated in the stable, and walk from thence to the course, and after running, he may return to the stables in his plates, and continue wearing them until he has performed his engagements for the meeting, which seldom exceeds three days. The groom will not want to do any work with the horse, as his first day's race will keep the length in him. If he requires any thing in the way of exercise, it can only be walking, or at furthest, a short hill gallop, both of which he may accomplish in his plates, without injury to his feet.—*Darvill.*

**RACE RIDING.** The person who is to ride a race, beside the grand requisite of honesty, should have abilities which qualify him for the performance: first, his strength should be sufficient to hold, support, and assist the horse, otherwise the horse will exhaust his wind. If he is necessitated to pull him together by raising his hands,

or throwing his weight out of centre, these checks produce an additional stress on the hocks or loins, which must tend to weaken or exhaust; and, if it is a close match, it is possible the heat might be lost by the riding. Therefore, that the horse may have every fair advantage, the rider should be strong enough to hold him without raising his hands, which might put the horse's head out of place, and though it were but an inch, this would be unpleasant and detrimental to him.—Next, his judgment should be able to discover, how the horse gallops with the greatest ease to himself, and this is a material thing to know, for no horse can be made the most of that is put out of his usual method of carrying himself; this being known or discovered, should be submitted to; what I mean by his usual method of carrying himself is, if he carries his head lower than is pleasant to the rider, if he is accustomed to bear more on one rein than the other, or has a favourite leg, for this is not the time to dispute or quarrel; you must find his favourite manner and comply with it.

The next consideration is, to start your horse coolly and temperately. If you flurry him at starting, his own eagerness will be very detrimental; therefore, endeavour to keep him moderate, that his gallop may be smooth and steady. You must give him all the support he requires from the hand in a smooth steady pull, and not increase it, unless his eagerness to get on necessitates you to do it; in which case, you must increase your pull, with the same steadiness as before, which will hold him and save his wind; but if you raise your hand to keep him in, you will raise his head out of place, which will put him to the fret, and he will be fighting for the ascendancy of the hand.

If you are necessitated to this, to prevent the horse from running away with you, your strength is not competent for such horse; nor must you throw your body out of centre, nor plant your feet forward to increase your pull without raising your hands: these operate to the disadvantage of the horse.

In situations where you are to push and do your utmost, you must assist the horse's efforts with the greatest exactness and judgment; without depriving the horse of the requisite support, your hand must permit him to extend himself to the utmost, and assist him in collecting himself together. This is done by permitting the horse to draw your hand from your

body, to favour his extension, and as he collects himself the hand returns to the body, and assists him in collecting his haunches under him.

This action of the hands must be done with the nicest judgment, otherwise you would abandon, deceive, deter, and prevent, rather than assist the horse's exertion. Be mindful, therefore, that the hand does not move till the extension of the horse removes it; and, during this removal, that the hand affords the same support that the horse requires. When the horse gathers himself together, the reins would be slack if the hand was not to return back again, and the horse would not be able to bring his legs so close, as by the assistance of the rider's support he would be enabled to do. Therefore, as the horse gathers himself, the hand must return, yielding him that support which assists the haunches coming forward.

This skill of the rider is mostly displayed at the running in. Over-eagerness of the rider, flurry, or the like, may sometimes take place with young jockeys. I therefore caution gentlemen who choose to ride their own matches among themselves, to be collected at this time; for, if it is a near match, their winning or losing depends on the riding. The over-doing or under-doing their part is equally detrimental. For, were you to yield your hand too much, you abandon your horse; and, in gathering him together, if you over-do your part, you check his next extension: hence, a steady support must be given, which, at this crisis, must be neither more nor less than the horse requires.

Now let me explain the consequence of either. First, if you do not sufficiently support the horse, the consequence is, the horse dare not extend himself so far as he could under a confident support of the hand, because that support is a great assistance in gathering himself together; but the eagerness of the horse will make him extend himself as far as he can safely, independent of the hand, and the labour and exertion of gathering himself, without support from the hand, exhausts his wind and strength, and the horse is said to be blown. Therefore it is necessary that the rider's strength should hold out equal with that of the horse, since one depends so much on the other.

On the other hand, the support the hand is to afford, is to be no more than what the horse takes; for the hand is not to dictate to the horse at what rate he is

to pull; if the horse rides cool and steady, he will take a support equal to the rate or extension he is at; but, if hot and eager, he will require a greater support to restrain him from over-running and exhausting himself, and the hand must give support to prevent such consequences; but at the push or running in you must give him the liberty to exert his utmost, and so much support, and no more, than will enable him to do it—if you give him more you restrain him—if you give him less, he cannot confidently throw himself out.

If, in endeavouring to assist the horse, you pull him too much together, you check him, particularly if your horse is nearly spent; when you find the horse done pulling, it is time you had done running, for he is then exhausted, and must lose if the others are not in the same state. If you find your horse strong, and close pushed at running in, the application of the whip, given at the instant, before he takes his stroke, may draw an additional spring or two from him, and give you some assistance; but the whip and spurs, at other times, are of little service; the emulation and eagerness of horses will carry them beyond what they can hold, and the whip or spurs discourages, if too much or injudiciously applied.

You will observe in the hunting and racing systems of riding, that pressing the feet in the stirrups to increase your pull, is not allowable if it can be avoided, but particularly in racing, for you must thereby considerably increase your weight or pressure on the saddle; and, though it is called riding in the stirrups, when you ride properly, the stirrups sustain a very inconsiderable weight, and when the horse is extended and pulls fair, you may ride in the same position almost without the stirrups, as the grasp with the knees, and the pull of the horse, will keep your position steady.

Having pointed out what operates to the advantage and disadvantage of the horse's speed, the rest must be left to practice, which is to perfect every science; but without studying theory, practitioners, we find, are very apt to run into error.

**RACING, GENERAL RULES AND LAWS CONCERNING.** Horses take their ages from May-day; that is, a horse foaled any time in the year 1828, will be deemed a year old on the first of May, 1829.

Four inches are a hand.

Fourteen pounds are a stone.

Catch weights are, each party to appoint any person to ride without weighing.

A post match, is to insert the age of the horses in the article, and to run any horse of that age, without declaring what horse, till he come to the post to start.

Horses not entitled to start without producing a proper certificate of their age, if required, at the time appointed in the articles, except where aged horses are included, and in that case a junior horse may enter without a certificate as to age, provided he carry the same weight as the aged.

No person shall start more than one horse of which he is the owner, either wholly or in part, and either in his own name or in that of any other person, for any race for which heats are run.

The horse that has his head at the ending post first, wins the heat.

For the best of the plate, where three heats are run, the horse is second that wins one heat.

For the best of heats, the horse is second that beats the other horses twice out of three times, though he do not win a heat.

Where a plate is won by two heats, the preference of the horses is determined by the places they get in the second heat.

Where a plate or subscription is given for the winner of the best of three heats, a horse, to win the prize, must be the actual winner of two heats, even though no horse appear against him for both or either of the heats.

When three horses have each won a heat, they only must start for a fourth, and the preference amongst them will be determined by it, there being before no difference amongst them.

In running of heats, if it cannot be decided which horse is first, the heat goes for nothing, and they may all start again, except it be between two horses that had each won a heat.

If a rider fall from his horse, and the horse be rode in by a person who is sufficient weight, he shall take his place the same as if his rider had not fallen, provided he go back to the place where the rider fell.

Jockeys must ride their horses to the usual place for weighing the riders, and he that dismounts before, or wants weight, is distanced; unless he be disabled by an accident which should render him incapable of riding back, in which case he may be led or carried to the scale.

Horses' plates or shoes not allowed in the weight.

Horses running on the wrong side of a post, and not turning back, are distanced.

Horses drawn before the plate is won are distanced.

Horses are distanced if their riders cross or jostle.

All complaints of foul riding must be made before or at the time the jockey is weighed.

No distance in a fourth heat.

A confirmed bet cannot be off but by mutual consent, except in the cases hereinafter mentioned.

Either of the betters may demand stakes to be made, and on refusal, declare the bet to be void.

If a better be absent on the day of running, a public declaration of the bet may be made on the course, and a demand whether any person will make stakes for the absent party, and if no person consent to do so, the bet may be declared void.

Bets agreed to be paid or received in London, or any other specified place, cannot be declared off on the course.

If a match or sweepstakes be made for any specified day in any race-week, and the parties agree to change the day to any other in the same week, all bets must stand; but if the parties agree to run the race in a different week, all bets made before the alteration shall be void.

The person who lays the odds has a right to choose a horse or the field; when a person has chosen a horse, the field is what starts against him; but there is no field without one horse starts against him.

Bets and stakes made in guineas are paid in sovereigns.

If odds are laid without mentioning the horse before the race is over, the bet must be determined by the state of the odds at the time of making it.

Bets made in running are not determined till the plate is won, if that heat be not mentioned at the time of running.

A bet made after the heat is over, if the horse betted on does not start, is void.

Bets determined, though the horse does not start, when the words "play or pay," are made use of in betting.

Where two horses run a dead heat for a sweepstakes or plate, and the parties agree to divide the stakes equally, all bets between those two horses, or between either of them, and the field, must be settled by the money betted being put together and divided equally between the parties. If, after the dead heat, an un-

equal division of the stakes be agreed upon, then the money betted shall be put together, and be divided between the parties in the same proportion as the stakes shall have been divided. If a bet be made on one of the horses that ran the dead heat against a horse that was beaten in the race, he who backed the horse that ran the dead heat wins half his bet. If the dead heat be the first event of a double bet, the bet shall be void.

Bets made on horses winning any number of races within the year, shall be understood, however the expression may be varied, as meaning the year of our Lord.

Money given to have a bet laid shall not be returned, though the race be not run.

Matches and bets are void on the decease of either party before the match or bet is determined.

A horse walking over or receiving forfeit shall not be deemed a winner.

An untried stallion or mare is one whose produce has never run in public.

A maiden horse or mare is one that has never won.

Give and take plates, are weight for inches: twelve hands to carry a stated weight, all above to carry extra, in the proportion of 7lb. to an inch.

Any person that shall run a horse, mare, or gelding, for less value than fifty pounds, forfeits the sum of two hundred pounds.

Every person that shall print, publish, advertise, or proclaim any money or other thing to be run for of less value than fifty pounds, forfeits the sum of one hundred pounds.

Horses may run for any sum on Newmarket Heath, in the county of Cambridge and Suffolk, and Black-Hambleton, in the county of York, without incurring any penalty.—See HANDICAP, p. 415.

**RACK.** The railed convenience constructed above the manger in a stable for the reception of hay, is so called. It should be so formed, as to have alternate openings at the bottom, for the dust and seeds to pass through: and although it is become a practice exceedingly prevalent, to have the rack on one side, instead of the centre of the stall, there is no good or rational plea can be advanced in justification of such innovation: on the contrary, it compulsively accustoms the horse to stand with his hind quarters mostly on one side of the stall, by which his bedding is constantly and

inevitably deranged almost as soon as it is set fair.

**RAKING** is the old and ridiculous (or rather unnatural) custom of oiling the hand, and introducing it at the sphincter of the anus, to extract the indurated dung, when the horse labours under severe inflammatory colic, arising from previous constipation. The only reason adduced to justify the practice is, its being one means of obtaining immediate relief; and if that relief could be readily obtained to a certainty, the adoption could not with propriety be so totally condemned. The fact is, that this custom, like many others in the old code of veterinary law, is only a powerful shield for the protection of indolence; for one clyster would do more in liquifying and bringing away the hardened fœces, than back-racking (as it is called) would effect in an hour.

**RANGER.** An office of trust appertaining to the laws of a forest, where there are generally two, as principal and deputy ranger; to the latter of whom the executive department more materially extends: it is his particular province to take occasional cognizance of all matters within the limits (or what are termed purlieus) of the forest, and to make presentation of all offences and offenders at the proper courts when held. It is an office of honour, greatly superior to a keeper, a bailiff, or other subordinate.

**RANGIFER.** A kind of stag, so called from his lofty horns resembling the branches of trees.

**RAT-TAIL.** A horse having a long dock, and little or no hair upon it, is said to be rat-tailed.

**RAT-TAILS.** Excrescences which creep from the pastern to the middle of the shank of a horse; so called from their resemblance to a rat's tail. Some are moist; others dry: the former may be treated as in the cure of the grease; and the latter with the following mercurial ointment.

Take of Crude mercury, one ounce;

Venice turpentine, half an oz.

Rub them together in a mortar, till the globules of the quicksilver are no longer visible; then add

Hog's lard, two ounces.

Mix.

If the hardness does not submit to the last medicine, it is usually pared off with a knife, and dressed with turpentine, tar, and honey, to which verdigrease, or white vitriol, are occasionally added. Before

the use of the knife, however, Bartlet advises this ointment :

Take of Black soap, four ounces ;  
Quick-lime, two ounces ;  
Vinegar enough to make an  
ointment. Mix.

**RATTLING IN THE HEAD.** When a horse is heard to rattle in the head, it denotes obstructions, and affords ample proof that a cold has been recently caught,

or the glandular secretions impeded. Such rattlings being loud and frequent, (or rather incessant,) with large indurated tumefactions underneath the jaw, accompanied by a slimy, viscid, fœtid, discoloured discharge from the nostrils, danger should be instantly guarded against, as farcy or glanders will most probably ensue.

**RAVEN.** The raven is an inhabitant not only of our own island, but also of most other parts of the world.—Among the ancients it was esteemed a bird of much importance in augury ; and the various changes and modulations of its voice were studied with the greatest attention, and were too often used by designing men to mislead the unwary.

It frequents the neighbourhood of great towns ; where it is useful in devouring the carrion and filth, which it scents at a vast distance. It is a cunning bird, and generally careful in keeping beyond the reach of a gun.

When brought up young, the raven becomes very familiar ; and, in a domestic state, he possesses many qualities that render him highly amusing. Busy, inquisitive, and impudent, he goes every where, affronts and drives off the dogs, plays his tricks on the poultry, and is particularly assiduous in cultivating the good-will of the cook-maid, who is generally his favourite in the family. But with the amusing qualities, he often also has the vices and defects of a favourite. He is a glutton by nature, and a thief by habit. He does not confine himself to petty depredations on the pantry or the larder ; he aims at more magnificent plunder—at spoils that he can neither exhibit nor enjoy, but which, like a miser, he rests satisfied with having the satisfaction of sometimes visiting and contemplating in secret. A piece of money, a tea-spoon, or a ring, is always a tempting bait to his avarice : these he will slyly seize upon, and, if not watched, will carry to his favourite hole.

Mr. Montagu was informed by a gentleman, that his butler having missed many silver spoons, and other articles, without being able to account for the mode in which they disappeared, at last observed a tame raven, that was kept about the house, with one in his mouth ; and, on watching him to his hiding place, discovered there upwards of a dozen more.

Notwithstanding the injury these birds do to the farmer, a popular respect is paid to them, from their having been the birds that fed the prophet Elijah in the wilderness. This prepossession in favour of the raven is of very ancient date ; since the Romans themselves, who thought the bird ominous, paid to it, from motives of fear, the most profound veneration.

A raven, as Pliny informs us, that had been kept in the temple of Castor, flew down into the shop of a tailor, who was highly delighted with its visits. He taught the bird several tricks ; but particularly to pronounce the names of the Emperor Tiberius, and the whole

## R A V E N

royal family. The tailor was beginning to grow rich by those who came to see this wonderful raven ; till an envious neighbour, displeased at his success, killed the bird, and deprived the tailor of all his hopes of future fortune. The Romans, however, thought it necessary to take the poor tailor's part ; they accordingly punished the man who offered the injury, and gave the raven all the honours of a magnificent interment.

The female builds her nest early in the spring, in trees and the holes of rocks ; in which she lays five or six bluish-green eggs, spotted with brown. She sits about twenty days ; during which time she is constantly attended by the male, who not only provides her with abundance of food, but, whenever she leaves the nest, takes her place.

Of the perseverance of the raven in the act of incubation, Mr. White has related the following singular anecdote :—In the centre of a grove near Selborne, there stood an oak, which, though shapely and tall on the whole, bulged out into a large excrescence near the middle of the stem. On this tree a pair of ravens had fixed their residence for such a series of years, that the oak was distinguished by the title of “the raven tree.” Many were the attempts of the neighbouring youths to get at this eyry : the difficulty whetted their inclinations, and each was ambitious of surmounting the arduous task ; but when they arrived at the swelling, it jutted out so in their way, and was so far beyond their grasp, that the boldest lads were deterred, and acknowledged the undertaking to be too hazardous. Thus the ravens continued to build, nest upon nest, in perfect security, till the fatal day arrived on which the wood was to be levelled. This was in the month of May, when those birds usually sit. The saw was applied to the trunk, the wedges were inserted into the opening, the woods echoed to the heavy blows of the beetle or mallet, the tree nodded to its fall ; but still the dam persisted to sit. At last, when it gave way, the bird was flung from her nest ; and, though her parental affection deserved a better fate, was whipped down by the twigs, which brought her dead to the ground.

The raven feeds chiefly on small animals ; and is said to destroy rabbits, young ducks, and chickens ; and sometimes even lambs, when they happen to be dropped in a weak state. In the northern regions, it preys in concert with the white bear, the arctic fox, and the eagle ; it devours the eggs of other birds, and eats shore-fish, and shell-fish ; with the latter it soars into the air, and drops them from on high to break the shells and thus get at the contents. In the act of feeding, it shifts its prey from the bill to the feet, and from the feet to the bill, to ease itself. Willoughby says, that it may be trained to fowling, like a hawk.

Le Vaillant found a variety of the raven, differing from our's in size only and the greater curvature of its beak, in Saldanha-bay, at the Cape of Good Hope ; where, he informs us, it unites in large flocks, often attacking and killing the young antelopes.

Its faculty of scent must be very acute ; for in the coldest of the winter-days, at Hudson's Bay, when every kind of effluvia is almost

instantaneously destroyed by the frost, buffaloes and other beasts have been killed where not one of these birds was seen; but in a few hours, scores of them would gather about the spot to pick up the offal and blood.

The flesh of the raven is eaten by the natives of Greenland. They likewise use the skins sewed together as an inner garment, and form the split quills into fishing lines. The quills are in great request in our own country for the tuning of harpsichords.

**RE-AFFORESTED.** Is where a forest has been disafforested, and again made forest, as the Forest of Dean was, by an act of parliament, in the 20th of Charles II.

**REARING.** The ingenuity of man (says Adams) could not devise more means, than the horse does, to foil his rider. And though this subject properly belongs to horse-breaking, yet, as gentlemen have horses occasionally, that shew a disposition to be restive, it is proper they should, at least, know how to protect themselves from injury.

Of all the defences a horse makes, that of rearing is the most dangerous, when they rise rapidly and so unexpectedly, as you are scarcely aware of them, and so high as to endanger their falling backwards; it is fortunate a horse that rears to this extreme seldom or never kicks; you have, therefore, principally to guard against the rearing, and, when he takes you unawares, your body must come forward close to his neck, and your hands forward, on each side, even to clasp him round the neck, if you find it necessary.

To break horses of this dangerous vice, I have been in situations where I found it expedient to quit the horse, and alighting on my feet, have pulled the horse backwards; but these, though effective expedients, are only to be attempted at a particular crisis, and by persons perfectly collected, active, and agile. It so frightens a horse to be thus foiled, that he is wary of giving you the opportunity of serving him so again. I do not recommend gentlemen to attempt it; but whenever you are aware of the horse's disposition to rear, have your reins separated, and be prepared for him, and the instant you perceive him going to rise, slack the one hand, and bend him with the other, keeping your hand low. This bending compels him to move a hind leg, and being thrown off his balance, he of necessity comes down. Twist him round two or three times, to convince him of your superiority. It likewise confuses and

baffles him. By these means you may deter a horse from rearing to any dangerous height; and, after he has convinced himself by a few experiments, he will give it up for that time.

Every horse has a favourite side, on which he is prepared for defence; your attack must, consequently, be on his weak or unprepared side:—not only on this, but in every other instance. A horse that is addicted to kick high, seldom or never rears high, unless the firmness of your hand compels him to it. If your hand confines the head, as has been directed, you may bid defiance to his kicking; and, when a horse finds his defences do not avail, he wisely gives it over; but the twisting a horse round a few times for this vice will have its effect; if you seize a favourable opportunity to attack his feeble side, and have the advantage to twist him without his power of resistance, his astonishment and confusion will deter him from farther contention, unless you provoke it by ill-timed correction, passion, exultation, and the like.

Whatever passion possesses the rider, whether anger, revenge, cruelty, &c. it has the same effect on the horse's mind, as it would on our's, and prevents that concord and unity taking place, which ever should subsist between the rider and the horse. Therefore, the rider, who should be the most rational being, must always be disposed to amity, and should never suffer the most obstinate resistance of the horse to put him out of temper. If the contest does not demand his utmost exertions of strength, he should be able to hum a tune, or converse with the same composure and indifference as though the horse was all obedience; by this means, the instant a horse finds himself foiled, he desists, having no provocation to contend farther, and is abashed at his own weakness.

**RECEIPTS FOR MAKING BOOTS AND SHOES RESIST WATER.** One pint of linseed oil, half a pound of mutton suet, eight ounces of bees' wax, and one

pennyworth of rosin :—the whole to be boiled together, and warmed before using.

*Another.*—If the shoes are new, take half a pound of bees' wax, a quarter of a pound of rosin, and one pound of tallow : to be boiled well together, and warmed before using.

Indian rubber dissolved in spirits of turpentine, and spread over the boot or shoe previous to using the blacking, is highly advisable.

N. B. It is hardly necessary to mention, that the shoes should be cleaned well from the dirt, and perfectly dry, before the application of either of these receipts.

Shoe-soles can have a layer of cork or waxed canvas introduced between.—This will be found a very excellent precaution.

*Water-proof Composition.*—If it be wished to render copper caps water-proof, a small portion of the following composition should be inserted in each, which will not prevent the ignition of the priming :

Tallow . . . 2 parts.

Hog's lard . . 1 do.

White soap . . 3 do.

Caps may be purchased water proof.

**RE-CHASING.** A sporting term but little known, and never used, except in the official language of the forest and its environs. Re-chasing is the discovery and driving home of outlying deer and other beasts, to the district from whence they had strayed.

**RECHEAT.** Is a recal of the hounds by the horn.

**REDSHANK.** See **POOL SNIPE.**

**REGULUS.** A bay horse, foaled in 1739, bred by Lord Chedworth, at whose death he was sold to Mr. Martindale, being at that time a maiden horse.

Regulus was got by Lord Godolphin's Arabian, out of that noted and valuable mare Grey Robinson.

In 1745, Regulus (in the name of Sweetlips) won 50l. carrying 12st. at Epsom, beating Mr. Teddon's Poppet, Mr.

Grisewood's Brisk, and Mr. Greville's Chance. He was then named Regulus, and in the same year won the king's plate at Winchester, beating Mr. Grisewood's Teazer; walked over for the king's plate at Salisbury; won the king's plate at Nottingham, beating Mr. Hutton's Wormwood, Mr. Vavasour's Champion, and distanced two others; the king's plate at Canterbury, beating Mr. Grisewood's Teazer; the king's plate at Lewes, beating Mr. Smith's Grey Lincoln; the king's plate at Lincoln, beating Mr. Vavasour's Champion; and the king's plate at Newmarket in October, beating Lord Portmore's Grey Lincoln, and Mr. Everett's Lowther: Regulus won the first heat so very easy, that Lord Portmore and Mr. Everett withdrew their horses. At Newmarket in April, 1746, he won the king's plate, beating, easy, Mr. Grisewood's Teazer, which was drawn after the first heat.

Regulus, at six years old, won eight royal plates and a 50l. plate.—He was never beat, and was much superior to any other horse of his time.

Regulus then became a favourite and very valuable stallion in the north of Yorkshire, and was sire of an uncommon number of racers, stallions, and brood mares; notwithstanding, it has been asserted that Mr. Martindale cleared by him, as a stallion, little more than 1000gs. He got Careless, Cato, Trajan, Morwick-Ball, Adolphus, Sejanus, Elephant, Jalap, Æolus, South, Prophet, Turk, Vampire, Denmark, Bucephalus, A-la-greque, &c.—He got the dam of Eclipse, the dam of Tandem, the dam of Revenge, the dam of Angelica, Curiosity, Snapdragon, &c. the dam of Miss West, &c. the grandam of High-flyer, the great-grandam of Sir Peter Teazle, and many others.

Regulus died at Low-Gaterley, near Catterick, Yorkshire, in 1765, aged 26. He covered at 10gs. and 5s.

**REIN-DEER.** Of all animals of the deer kind, the rein-deer is the most extraordinary and the most useful. It is a native of the icy regions of the north; and though many attempts have been made to accustom it to a more southern climate, it shortly feels the influence of the change, and in a few months declines and dies. Nature seems to have fitted it entirely to answer the necessities of that hardy race of mankind that live near the pole. As these would find it impossible to subsist among their barren, snowy mountains without its aid, so this animal can live only there, where its assistance is most absolutely necessary. From it alone the natives of Lapland and Greenland supply most of their wants; it answers the purposes of a

## R E I N - D E E R

horse to convey them and their scanty furniture from one mountain to another ; it answers the purposes of a cow, in giving milk ; and it answers the purposes of the sheep, in furnishing them with a warm, though an homely, kind of clothing. From this quadruped alone, therefore, they receive as many advantages as we derive from three of our most useful creatures ; so that Providence does not leave these poor outcasts entirely destitute, but gives them a faithful domestic, more patient and serviceable than any other in nature.

The rein-deer resembles the American elk in the fashion of its horns. It is not easy in words to describe their minute differences ; nor will the reader, perhaps, have a distinct idea of the similitude, when told that both have brow antlers, very large, and hanging over their eyes, palmated towards the top, and bending forward like a bow. But here the similitude between these two animals ends ; for, as the elk is much larger than the stag, so the rein-deer is much smaller. It is lower and stronger built than the stag ; its legs are shorter and thicker, and its hoofs much broader than in that animal ; its hair is much thicker and warmer ; its horns much larger in proportion, and branching forward over its eyes ; its ears are much larger ; its pace is rather a trot than a bounding, and this it can continue for a whole day ; its hoofs are cloven and moveable, so that it spreads them abroad as it goes, to prevent its sinking in the snow. When it proceeds on a journey, it lays its great horns on its back, while there are two branches which always hang over its forehead, and almost cover its face. One thing seems peculiar to this animal and the elk ; which is, that as they move along, their hoofs are heard to crack with a pretty loud noise. This arises from their manner of treading ; for as they rest upon their cloven hoof, it spreads on the ground, and the two divisions separate from each other, but when they lift it, the divisions close again, and strike each other with a crack. The female also of the rein-deer has horns as well as the male, by which the species is distinguished from all other animals of the deer kind whatsoever.

When the rein-deer first shed their coat of hair, they are brown ; but in proportion as summer approaches, their hair begins to grow whitish ; until, at last, they are nearly grey. They are, however, always black about the eyes. The neck has long hair, hanging down, and coarser than upon any other part of the body. The feet, just at the insertion of the hoof, are surrounded with a ring of white. The hair in general stands so thick over the whole body, that if one should attempt to separate it, the skin will no where appear uncovered : whenever it falls also, it is not seen to drop from the root, as in other quadrupeds, but seems broken short near the bottom ; so that the lower part of the hair is seen growing, while the upper falls away. The horns of the female are made like those of the male, except that they are smaller and less branching. As in the rest of the deer kind, they sprout from the points ; and also in the beginning are furnished with a hairy crust, which supports the blood vessels, of most exquisite sensibility. The rein-deer shed their horns, after rutting time, at the latter end of November ; and they are not com-

## R E I N - D E E R

pletely furnished again till towards spring. The female always retains her's till she brings forth, and then sheds them about the beginning of November. If she be barren, however, which is not unfrequently the case, she does not shed them till winter. The castration of the rein-deer does not prevent the shedding of their horns: those which are the strongest cast them early in winter; those that are more weakly not so soon. Thus, from all these circumstances, we see how greatly this animal differs from the common stag. The female of the rein-deer has horns, which the hind is never seen to have: the rein-deer, when castrated, renews its horns, which we are assured the stag never does; it differs not less in its habits and manner of living, being tame, submissive, and patient; while the stag is wild, capricious, and unmanageable.

The rein-deer, as was said, is naturally an inhabitant of the countries bordering on the arctic circle. It is not unknown to the natives of Siberia. The North Americans also hunt it under the name of the *carribou*. But in Lapland, this animal is converted to the utmost advantage; and some herdsmen of that country are known to possess above a thousand in a single herd.

Lapland is divided into two districts, the mountainous and the woody. The mountainous part of the country is at best barren and bleak, excessively cold, and uninhabitable during the winter; still, however, it is the most desirable part of this frightful region, and is most thickly peopled during the summer. The natives generally reside on the declivity of the mountains, three or four cottages together, and lead a cheerful and social life. Upon the approach of winter, they are obliged to migrate into the plains below, each bringing down his whole herd, which often amounts to more than a thousand, and leading them where pasture is in the greatest plenty. The woody parts of the country are much more desolate and hideous. The whole face of nature there presents a frightful scene of trees without fruit, and plains without verdure. As far as the eye can reach, nothing is to be seen, even in the midst of summer, but barren fields, covered only with a moss almost as white as snow; no grass, no flowery landscapes; only here and there a pine tree, which may have escaped the frequent conflagrations by which the natives burn down their forests. But what is very extraordinary, as the whole surface of the country is clothed in white, so, on the contrary, the forests seem to the last degree dark and gloomy. While one kind of moss makes the fields look as if they were covered with snow, another kind blackens over all the trees, and even hides their verdure. This moss, however, which deforms the country, serves for its only support, as upon it alone the rein-deer can subsist. The inhabitants, who, during the summer, lived among the mountains, drive down their herds in winter, and people the plains and woods below. Such of the Laplanders as inhabit the woods and the plains all the year round, live remote from each other, and having been used to solitude, are melancholy, ignorant, and helpless. They are much poorer also than the mountaineers; for, while one of the latter is found to possess a thousand rein-deer at a time, none of the former are ever known to

## R E I N - D E E R

rear the tenth part of that number. The rein-deer makes the riches of this people: and the cold mountainous parts of the country agree best with its constitution. It is for this reason, therefore, that the mountains of Lapland are preferred to the woods; and that many claim an exclusive right to the tops of hills, covered in almost eternal snow. As soon as the summer begins to appear, the Laplander, who had fed his rein-deer upon the lower grounds during the winter, then drives them up to the mountains, and leaves the woody country, and the low pasture, which at that season are truly deplorable. The gnats bred by the sun's heat in the marshy bottoms, and the weedy lakes with which this country abounds more than any other parts of the world, are all upon the wing, and fill the whole air like clouds of dust in a dry windy day. The inhabitants, at that time, are obliged to daub their faces with pitch, mixed with milk, to shield their skins from their depredations. All places are then so greatly infested, that the poor natives can scarcely open their mouths without fear of suffocation; the insects enter, from their numbers and minuteness, into the nostrils and the eyes, and do not leave the sufferer a moment at his ease. But they are chiefly enemies to the rein-deer: the horns of that animal being then in their tender state, and possessed of extreme sensibility; a famished cloud of insects instantly settles upon them, and drive the poor animal almost to distraction. In this extremity, there are but two remedies to which the quadruped, as well as its master, are obliged to have recourse. The one is, for both to take shelter near their cottage, where a large fire of tree-moss is prepared, which filling the whole place with smoke, keeps off the gnats, and thus, by one inconvenience, expels a greater; the other is, to ascend to the highest summit of the mountains, where the air is too thin, and the weather too cold, for the gnats to come. There the rein-deer are seen to continue the whole day, although without food, rather than to venture down to the lower parts, where they can have no defence against their unceasing persecutors. Besides the gnat, there is also a gadfly, that during the summer season, is no less formidable to them. This insect is bred under their skins, where the egg has been deposited the preceding summer; and it is no sooner produced as a fly, than it again endeavours to deposit its eggs in some place similar to that from whence it came. Whenever, therefore, it appears flying over a herd of rein-deer, it puts the whole body, how numerous soever, into motion; they know their enemy, and do all they can, by tossing their horns, and running among each other, to terrify or avoid it. All their endeavours, however, are too generally without effect; the gadfly is seen to deposit its eggs, which burrowing under the skin, wound it in several places, and often bring on an incurable disorder. In the morning, therefore, as soon as the Lapland herdsman drives his deer to pasture, his greatest care is to keep them from scaling the summits of the mountains where there is no food, but where they go merely to be at ease from the gnats and gadflies that are ever annoying them. At this time there is a strong contest between the dogs and the deer; the one endeavouring to climb up against the side of the hill, and to gain those summits that

## R E I N - D E E R

are covered in eternal snows ; the other forcing them down, by barking and threatening, and in a manner compelling them into the places where their food is in the greatest plenty. There the men and dogs confine them ; guarding them with the utmost precaution the whole day, and driving them home at the proper seasons for milking.

The female brings forth in the middle of May, and gives milk till about the middle of October. Every morning and evening, during the summer, the herdsman returns to the cottage with his deer to be milked, where the women have previously kindled up a smoky fire, which effectually drives off the gnats, and keeps the rein-deer quiet while milking. The female furnishes about a pint, which, though thinner than that of the cow, is, nevertheless, sweeter, and more nourishing. This done, the herdsman drives them back to pasture ; as he neither folds nor houses them, neither provides for their subsistence during the winter, nor improves their pasture by cultivation.

Upon the return of the winter, when the gnats and flies are no longer to be feared, the Laplander descends into the lower grounds ; and as there are but few to dispute the possession of that desolate country, he has an extensive range to feed his herd in. Their chief, and almost their only, food at that time, is the white moss already mentioned ; which, from its being fed upon by this animal, obtains the name of the *lichen rangiferinus*. This is of two kinds ; the woody lichen, which covers almost all the desert parts of the country like snow ; the other is black, and covers the branches of the trees in very great quantities. However unpleasing these may be to the spectator, the native esteems them as one of his choicest benefits, and the most indulgent gift of nature. While his fields are clothed with moss, he envies neither the fertility nor the verdure of the more southern landscape ; dressed up warmly in his deer-skin clothes, with shoes and gloves of the same materials, he drives his herds along the desert, fearless and at ease, ignorant of any higher luxury than what their milk and smoke-dried flesh affords him. Hardened to the climate, he sleeps in the midst of ice ; or awaking dozes away his time with tobacco ; while his faithful dogs supply his place, and keep the herd from wandering. The deer, in the mean time, with instincts adapted to the soil, pursue their food, though covered in the deepest snow. They turn it up with their noses like swine : and even though its surface be frozen and stiff, yet the hide is so hardened in that part, that they easily overcome the difficulty. It sometimes, however, happens, though but rarely, that the winter commences with rain, and a frost ensuing, covers the whole country with a glazed crust of ice. Then, indeed, both the rein-deer and the Laplander are undone ; they have no provision laid up in case of accident, and the only resource is to cut down the large pine trees that are covered with moss, which furnishes but a scanty supply ; so that the greatest part of the herd is then seen to perish without a possibility of assistance. It sometimes also happens, that even this supply is wanting ; for the Laplander often burns down his woods, in order to improve and fertilize the soil which produces the moss, upon which he feeds his cattle.

## R E I N - D E E R

In this manner, the pastoral life is still continued near the pole ; neither the coldness of the winter, nor the length of the nights ; neither the wildness of the forests, nor the vagrant disposition of the herd, interrupt the even tenor of the Laplander's life. By night and day he is seen attending his favourite cattle, and remains unaffected, in a season which would be speedy death to those bred up in a milder climate. He gives himself no uneasiness to house his herds, or to provide a winter subsistence for them ; he is at the trouble neither of manuring his grounds, nor bringing in his harvest ; he is not the hireling of another's luxury : all his labours are to obviate the necessities of his own situation ; and these he undergoes with cheerfulness, as he is sure to enjoy the fruits of his own industry. If, therefore, we compare the Laplander with the peasant of more southern climates, we shall have little reason to pity his situation ; the climate in which he lives is rather terrible to us than to him ; and as for the rest, he is blessed with liberty, plenty, and ease. The rein-deer alone supplies him with all the wants of life, and some of the conveniences ; serving to shew how many advantages nature is capable of supplying when necessity gives the call. Thus the poor little helpless native, who was originally, perhaps, driven by fear or famine into those inhospitable climates, would seem, at first view, to be the most wretched of mankind : but it is far otherwise ; he looks round among the few wild animals that his barren country can maintain, and singles out one from among them, and that of a kind which the rest of mankind have not thought worth taking from a state of nature ; this he cultivates, propagates, and multiplies ; and from this alone derives every comfort that can soften the severity of his situation.

The rein-deer of this country are of two kinds, the wild and the tame. The wild are larger and stronger, but more mischievous, than the others. Their breed, however, is preferred to that of the tame : and the female of the latter is often sent into the woods, from whence she returns home impregnated by one of the wild kind. These are fitter for drawing the sledge, to which the Laplander accustoms them betimes, and yokes them to it by a strap, which goes round the neck, and comes down between their legs. The sledge is extremely light, and shod at the bottom with the skin of a young deer, the hair turned to slide on the frozen snow. The person who sits on this, guides the animal with a cord, fastened round the horns, and encourages it to proceed with his voice, and drives it with a goad. Some of the wild breed, though by far the strongest, are yet found refractory, and often turn upon their drivers ; who have then no other resource but to cover themselves with their sledge, and let the animal vent its fury upon that. But it is otherwise with those that are tame ; no creature can be more active, patient, and willing : when hard pushed, they will trot nine or ten Swedish miles, or between fifty and sixty English miles, at one stretch. But in such a case, the poor obedient creature fatigues itself to death, and, if not prevented by the Laplander, who kills it immediately, it will die in a day or two after. In general, they can go about thirty miles without halting, and this without any great or dangerous efforts. This, which is the only

## R E I N - D E E R

manner of travelling in that country, can be performed only in winter, when the snow is glazed over with ice ; and although it be a very speedy method of conveyance, yet it is inconvenient, dangerous, and troublesome.

In order to make these animals more obedient, and more generally serviceable, they castrate them : this operation the Laplanders perform with their teeth : these become sooner fat when taken from labour ; and they are found to be stronger in drawing the sledge. There is usually one male left entire for every six females ; these are in rut from the feast of St. Matthew to about Michaelmas. At this time their horns are thoroughly burnished, and their battles among each other are fierce and obstinate. The females do not begin to breed till they are two years old, and then they continue regularly breeding every year till they are superannuated. They go with young above eight months, and generally bring forth two at a time. The fondness of the dam for her young is very remarkable ; it often happens that when they are separated from her, she will return from pasture, keep calling round the cottage for them, and will not desist until, dead or alive, they are brought and laid at her feet. They are at first of a light brown : but they become darker with age ; and at last the old ones are of a brown, almost approaching to blackness. The young follow the dam for two or three years ; but they do not acquire their full growth until four. They are then broken in, and managed for drawing the sledge ; and they continue serviceable for four or five years longer. They never live above fifteen or sixteen years ; and when they arrive at the proper age, the Laplander generally kills them for the sake of their skins and their flesh. This he performs by striking them on the back of the neck with his knife into the spinal marrow ; upon which they instantly fall, and he then cuts the arteries that lead to the heart, and lets the blood discharge itself into the cavity of the breast.

There is scarce any part of this animal that is not converted to its peculiar use. As soon as it begins to grow old, and some time before the rut, it is killed, and the flesh dried in the air. It is also sometimes hardened with smoke, and laid up for travelling provision, when the natives migrate from one part of the country to another. During the winter, the rein-deer are slaughtered as sheep with us ; and every four persons in the family are allowed one rein-deer for their week's subsistence. In spring they spare the herd as much as they can, and live upon fresh fish. In summer, the milk and curd of the rein-deer makes their chief provision ; and in autumn, they live wholly upon fowls, which they kill with a cross-bow, or catch in springes. Nor is this so scanty an allowance ; since, at that time, the sea fowls come in such abundance that their ponds and springs are covered over. These are not so shy as with us, but yield themselves an easy prey. They are chiefly allured to those places by the swarms of gnats which infest the country during the summer, and now repay the former inconveniences, by inviting such numbers of birds as supply the natives with food a fourth part of the year in great abundance.

## R E I N - D E E R

The milk, when newly taken, is warmed in a caldron, and thickened with rennet ; and then the curd is pressed into cheeses, which are little and well tasted. These are never found to breed mites as the cheese of other countries ; probably because the mite-fly is not to be found in Lapland. The whey which remains is warmed up again, and becomes of a consistence as if thickened with the white of eggs. Upon this the Laplanders feed during the summer ; it is pleasant and well tasted, but not very nourishing. As to butter, they very seldom make any, because the milk affords but a very small quantity, and this, both in taste and consistence, is more nearly resembling to suet. They never keep their milk till it turns sour ; and do not dress it into the variety of dishes which the more southern countries are known to do. The only delicacy they make from it is with wood-sorrel, which being boiled up with it, and coagulating, the whole is put into casks, or deer skins, and kept under ground to be eaten in winter.

The skin is even a more valuable part of this animal than either of the former. From that part of it which covered the head and feet, they make their strong snow-shoes with the hair on the outside. Of the other parts they compose their garments, which are extremely warm, and which cover them all over. The hair of these also is on the outside ; and they sometimes line them with the fur of the glutton, or some other warm-furred animal of that climate. These skins also serve them for beds. They spread them on each side of the fire, upon some leaves of the dwarf birch tree, and in this manner lie both soft and warm. Many garments made of the skin of the rein-deer are sold every year to the inhabitants of the more southern parts of Europe ; and they are found so serviceable in keeping out the cold, that even people of the first rank are known to wear them.

In short, no part of this animal is thrown away as useless. The blood is preserved in small casks, to make sauce with the marrow in spring. The horns are sold to be converted into glue. The sinews are dried, and divided so as to make the strongest kind of sewing thread, not unlike catgut. The tongues, which are considered as a great delicacy, are dried, and sold into the more southern provinces. The intestines themselves are washed like our tripe, and in high esteem among the natives. Thus the Laplander finds all his necessities amply supplied from this single animal, and he who has a large herd of them has no idea of higher luxury.

But, although the rein-deer be a very hardy and vigorous animal, it is not without its diseases. I have already mentioned the pain it feels from the gnat, and the apprehensions it is under from the gad-fly. Its hide is often found pierced in a hundred places, like a sieve, from this insect, and not a few die in their third year from this very cause. Their teats also are subject to cracking, so that blood comes instead of milk. They sometimes take a loathing for their food ; and, instead of eating, stand still and chew the cud. They are also troubled with a vertigo, like the elk, and turn round often till they die. The Laplander judges of their state by the manner of their turning. If they turn to the right, he judges their disorder but

slight; if they turn to the left, he deems it incurable. The rein-deer are also subject to ulcers near the hoof, which unqualifies them for travelling, or keeping with the herd. But the most fatal disorder of all is that which the natives call the *suddataka*, which attacks this animal at all seasons of the year. The instant it is seized with this disease, it begins to breathe with great difficulty; its eyes begin to stare, and its nostrils to expand. It acquires also an unusual degree of ferocity and attacks all it meets indiscriminately. Still, however, it continues to feed as if in health, but is not seen to chew the cud, and it lies down more frequently than before. In this manner it continues, every day consuming and growing more lean till at last it dies from mere inanition; and not one of these that are attacked with this disorder are ever found to recover. Notwithstanding, it is but very lately known in that part of the world; although, during the last ten or fifteen years, it has spoiled whole provinces of this necessary creature. It is contagious; and the moment the Laplander perceives any of his herd infected, he hastens to kill them immediately before it spreads any farther. When examined internally, there is a frothy substance found in the brain, and round the lungs; the intestines are lax and flabby, and the spleen is diminished almost to nothing. The Laplander's only cure in all these disorders, is to anoint the animal's back with tar; if this does not succeed, he considers the disease as beyond the power of art; and, with his natural phlegm, submits to the severities of fortune.

Besides the internal maladies of this animal, there are some external enemies which it has to fear. The bears now and then make depredations upon the herd; but of all their persecutors, the creature called the glutton is the most dangerous and the most successful. The war between these is carried on not less in Lapland than in North America, where the rein-deer is called the *carribou*, and the glutton the *carcajou*. This animal, which is not above the size of a badger, waits whole weeks together for its prey, hid in the branches of some spreading tree; and when the wild rein-deer passes underneath, it instantly drops down upon it, fixing its teeth and claws into the neck, just behind the horns. It is in vain that the wounded animal then flies for protection, that it rustles among the branches of the forest, the glutton still holds its former position, and, although it often loses a part of its skin and flesh, which are rubbed off against the trees, yet it still keeps fast hold till its prey drops with fatigue and loss of blood. The deer has but one method of escape, which is by jumping into the water: that element its enemy cannot endure; for, as we are told, it quits its hold immediately, and then thinks only of providing for its own proper security.

REINS. Are the parts of a bridle which are affixed to the eyes of the bit, or bits, on each side of a horse's mouth, pass up the horse's neck, and are united at the reverse end, where the junction of both are held in the hand of the rider. A snaffle-bridle, and a hard-and-sharp, have

each of them two reins; a Pelham and a Weymouth have each four.

REINS. The reins of a horse are the parts where the kidneys are seated; and the word is generally used in a synonymous sense with loins. When a disorder arises, or a defect is observed, in these

parts, it may be supposed to have originated in some short and sudden turn in a narrow stall; carrying too heavy a weight, or drawing too large a load. Whenever such injury is sustained, a difficulty of staling, partial dribblings, or the urine very high coloured, and tinged with blood, will soon point out the seat of the complaint.

**REINS, PILLAR.** Those affixed to the central pillars of a riding school are so called; as are those likewise, by which the horse is kept confined ready for his rider, when saddled, bridled, and turned round in his stall.

**RELAY.** A relay of horses is a supply of fresh ones fixed at some particular spot, to exchange upon a journey. A relay of hounds applies to hunting excursions, where a part of the pack is alternately detached to a certain place of destination, that the sport may be continued daily, without intermission.

**REPOSITORIES.** According to Dr. Johnson, a repository is a place where any thing is safely laid up; but we must extend the meaning of the word. Repositories are at present to be found numerous enough in London, and are to be met with in many of the large towns throughout the kingdom. They are establishments where horses, carriages, &c. are constantly on sale, and which, at stated (generally weekly) periods, are offered for sale by auction. Tattersall's celebrated establishment may be placed at the head of the list; and there are other repositories of respectability; but it must not be denied that at many of these places it behoves those to be on their guard who wish to make a purchase, since no means are left untried to deceive the unwary: it must be admitted also that many of these places afford facilities for the professed horse stealer to dispose of his infamously acquired commodity.

**RESTIVENESS** in horses proceeds from a bad disposition or temper, which obstinately refuses obedience, where he finds the rider has not sufficient skill or address to compel him; and I believe there would be fewer restive horses, if the persons first employed to break them, knew the method of foiling their defences, for want of which, the horse is too frequently successful; which encourages him to repeated and more determined trials, and the oftener he succeeds, the more he is confirmed in the vice. Horses of this disposition are exceedingly subtle, and watch their opportunity. They first,

as it were, feel for your firmness and resolution; if they find your seat strong, and you determined, they wait their opportunity of situation where they can attack you to advantage, and are sure to defend themselves at that point on which you will attack them.

Now the great object of the rider in these contests, is to frustrate the horse's intentions, and protect himself from injury in the struggle. The horse commences his attack generally by stopping, turning short round, mostly to the right hand, as taking the rider at the greatest disadvantage, because few men are so powerful with the left as the right hand, and the horse expects you will oppose the opposite hand to which he turns, to prevent him: he therefore designedly attacks your weakest hand, and is so prepared to defend himself against your utmost efforts, that it is vain to attempt it. But, instead of attempting to prevent him with your left hand, attack him rather with your right, and turn him completely round, so that his head is presented the way you were going. And here an application of the spurs may be tried, if it will compel him forward, but it seldom does. He generally turns round again, and you, in like manner, attacking his unguarded side, turn him two or three times, letting your heel and spur, if necessary, powerfully assist your hand, before he can arm or defend himself against it. Finding themselves baffled in the plot of their defence, some give it up, and go on; others will make a more obstinate resistance, and since he refuses to go the way you want him, you must studiously prevent his going any other: for which reason, finding him set himself against your endeavours to make him go forward, immediately change your attack, turn him about, and rein him backward. When a horse sets himself against going forward, he is easily compelled backward. Here his defence is again baffled, and this is ever to be your rule—never to contend with him on that point he is prepared to resist.

In these contests you must be collected, and have an eye to the surrounding objects, that you may not put yourself in an awkward situation, which through inattention you may do, without the design of the horse; but it frequently happens that restive horses try their utmost to get you into these situations, by sideling to other horses, carriages, walls, rails, the foot pavement, the houses, &c. &c.

Now it is so natural for persons to

pull the horse from the object that he makes for, that we do not wonder to see it practised; but this gives a determined horse the completest opportunity of accomplishing his intention; therefore, admitting it to be a wall,—a riding house is surrounded with walls, and a restive horse would be always crushing your knee against it, if we had not the means to prevent him. Therefore, whenever we find the horse so disposed, instead of pulling him from the wall, we bend his head to the wall, by which the side next the wall is in a concave position, which prevents his utmost endeavours from doing you any injury.

But in the streets, or on the roads, innumerable objects more dangerous than a wall, will present themselves, which you must be attentive not to come near. But the instant you apprehend or perceive him sideling to any object, turn his head to that object, and back him from it. By this means you protect yourself from injury, and foil his intentions; consequently, after a fruitless contest, the horse is necessitated to submit. The application of whip or spurs in these contests, more than to shift the croup, or give efficacy to your hands, is of so little use, that I dare not mention them, for correction injudiciously applied does great mischief; and many people's passions have no bounds when they begin; and, since I know a horse's vices can be subdued without it, I recommend no correction, rather than an immoderate or ill-timed one; for it is impossible for me here to specify the instant it should be given, or the severity I might adopt myself. This must be left to the discretion of the rider, and discretion will seldom apply the spurs sharply more than twice, or three times.

I don't mean to infer, that correction is never to be given; some horses require it; others that have not a vice belonging to them, are made desperate from injudicious punishment: the rider should have judgment to discover the temper and disposition of the horse, which is to determine, in a great measure, the nature and proportion of his punishment; but to repeat the spurs and whip, to make a horse go forward when he refuses, is certainly wrong. He must be immediately manœuvred by the hands, by turning about and about, reining back, and the like, till he finds his designs, whatever they were, frustrated; he will then, finding he can go no other, reluctantly go your way, and when you present his head for that pur-

pose, you may apply the spurs sharply, which is compelling him at last to obey the spurs, which he at first refused.

A horse's defences in the above instances, in a manner defeat their own purpose, because you immediately convert their defence to their punishment. But there are some few horses who fix themselves like stocks, setting all your endeavours at defiance, to move them. There they set up a defence that can no way endanger your person; were they to move, you could convert that to your purpose, but while they stand as stocks, they defy you to move them forward, backward, to right or left. This defence must also be converted to punishment: let them stand, and make no attempt to move them, and you will find in a short space, frequently less than a minute, they will move of themselves. If you have patience to sit on their backs, and keep them there for a time, it is the most proper punishment for the offence, and will surely cure that mode of defence.

Though I have here set forth a method of manœuvre, with little or no correction, I am sensible that many persons (if they possessed the skill) have not the patience to adopt it, but will let their passion overcome their reason, and whip and spur will be rigorously applied. Some horses are of such an abject spirit, that they may be beat out of their sulks; others you are obliged to manœuvre, and those riders that cannot keep their temper, apply the whip and spurs.

Now, the pulling and twisting a horse about, is what beats him, and when done with judgment soon overcomes and secures your safety. But when injudiciously applied, the contest is generally longer, and the rider exposed to imminent danger.—Should he escape unhurt, and worry the horse out, he attributes his success to the resolute application of the whip and spurs, which, I am of opinion, too frequently prolongs the contest. Nevertheless, the multitude are apt to mistake such temerity for skilful horsemanship, for they are eye witnesses of the resolution and courage of the rider, but are ignorant that the end might have been obtained by a more mild, certain, and safe, method. For when the rider loses his temper, which a brutal application of the whip and spurs is a certain indication of, his thoughts are not collected, and his operations are without judgment; he provokes a more violent resistance, precipitates himself into dangerous situations, (which,

if he had been cool and collected, he might easily have avoided,) and the contest becomes imminently dangerous, and very doubtful; and if no disaster happens to the rider, it terminates by consent of the horse in a respite for the present; he submits for the moment, that he may recover strength to renew the attack, for he does not seem to consider himself defeated.

**RESUSCITATION.** The reviving or raising again to a state of action, an animal whose vital powers have been suspended by any accident, as by hanging, suffocation, drowning, &c. Mr. Feron observes, that the too common practice of leaving a mare in places unsuitable for her foaling, or exposing her in a field amongst other horses, frequently produces fatal accidents.—“Every one knows (says he) that there is not a year passes, but we hear of foals being smothered in ditches, or drowned in ponds or rivulets, after having been unmercifully bruised, or their bones fractured,” &c.

Those who advert to the various causes that may suspend life, will find that too hasty a decision, as to its final extinction, is by no means to be commended. Without having previously employed all the resources, that humanity and the veterinary art may suggest, we are by no means justifiable in supposing animals irrecoverable when the accident is recent.

“The first treatment in cases of suspended animation (says Mr. Feron) whatever may be the cause, should be directed to excite a susceptibility of stimuli; and next, for restoring susceptibility itself. An advantage so essential must induce us to be particularly careful in the choice and application of stimulant medicines, and not to administer such as are too powerful at first, which would indeed excite irritability, but in too violent a degree; and it is also deserving attention, that in the beginning of the process, when susceptibility of irritation is but slight, violent stimulants may be pernicious, by tending to suppress the latent sparks of life. But by a due proportion in the administration of those medicines, and being skilfully managed, the action and reaction of the vital power may be restored, and the system again become susceptible of stimuli.

It is difficult, and sometimes impossible, to discover, whether or no the vital principle is entirely suppressed. The susceptibility of irritation may be completely suppressed, and the animal, apparently

dead, may be insensible to the effect of the strongest stimuli, such as the operation of the knife, and effects of a red hot iron; and yet the vital power may not be extinct. The state of life is manifested from all the symptoms of animation. In this case, irritability is not impeded in its free progressive action; respiration, pulse, and animal heat, are somewhat perceptible.”

These and the subsequent remarks of this judicious writer will be sufficient to point out the rashness and impropriety of consigning to the kennel, a colt of considerable value, before the following treatment has been fairly and fully tried.

“If a colt is foaled apparently dead, in a place where but little or no assistance can be got, let his tongue be immediately stimulated, rubbing it with common salt. This stimulant may promote expectoration, and thus admit the external air freely: I have seen several instances of colts, foaled apparently dead, recovering all the symptoms of animation in less than twenty minutes. Instilling a few drops of volatile spirit into the inner corners of the eyes, may likewise operate with good effect; but, should the case prove obstinate, and vitality continue suppressed, the application of the actual cautery must be resorted to, or a red hot iron passed on one or both sides of the chest and under the belly. Cutting the skin in front of the chest, under the belly, and other places where rowels are admissible, is also advisable, as well as rubbing the legs well with oil of turpentine.

If any signs of life should be perceptible, then it would be an excellent practice to supply the blood with a greater proportion of oxygen gas, pure or diluted with atmospheric air. Stimulating the nostrils with the vapours of vitriolic acid, or marine acid, will also be a very proper application.

But a more proper method of immediately stimulating the heart and arteries, would be, by transfusing new blood into them. This operation deserves particular attention, in cases of suspended animation. It is performed by injecting the blood that comes out of the artery of a calf or sheep, into the jugular vein of a colt that is apparently dead at the same time he is foaled; and is done in the following manner, viz.

The animal you wish to kill, in order to save the other, must be well secured, and laid as near the other as possible. Then a longitudinal incision must be made

in its neck, that you may find the carotid artery, which lies along side, and immediately under, the jugular vein (or vein of the neck); having previously secured two injecting pipes, such as those used for injecting anatomical preparations, at each end of a tube long enough to reach from one animal to the other. One of these pipes must be introduced into the carotid artery of the calf, and the other into the jugular vein of the colt apparently dead; the artery must be well secured with a ligature just under the pipe, until the other pipe is properly fixed into the vein of the colt, or other animal, that we suppose to be in a state of suspended animation only. When the apparatus is ready, you may cut the ligature of the carotid artery of the calf; you will then see the blood, that comes immediately from the heart, running from one animal to the other."

Mr. Feron assures us, that "this operation is almost certain to restore life, if the organic fibres of the heart and arteries can be at all affected by stimulants;" and we confess there appears to be a considerable degree of probability in the attempt.

**RETRIEVER, THE.** In cover shooting, and particularly since the *battu* system has been introduced, a retriever has been found essentially serviceable. A water spaniel is perhaps as well calculated for this purpose as any ramification of the dog. The reader need scarcely be informed, that the duty of the animal in question, is to fetch the game when killed.

**RHEUMATISM** (says the judicious Feron) is certainly a very common complaint in the human subject; but whether this disease ought, or ought not, to be considered, in a modern veterinary work, as a genus of disorder belonging to the brute species, is not yet sufficiently determined, nor proved by experience and observation.

We know that many horses become lame without any apparent cause; yet this does not sufficiently warrant us to pronounce with certainty, that it is positively produced by rheumatism: because his lameness may arise from injuries done to, or violence exercised on, this noble animal, and not from rheumatism, as many old farriery writers supposed it to be: their works being, for the most part, compiled from the practice of medicine and surgery, adapted to the human subject, they have not discriminated between the structure and diseases of the human and brute species, and have described

many diseases as common to both, which in reality belong to the former only, but never affect the horse nor any other quadruped.

It is thus the ignorant practitioner, when he cannot find out the seat of the complaint, immediately pronounces that it is a rheumatism; whilst the more minute investigation of the enlightened, soon find the disease to be in some other place, and of a nature very different from rheumatism. Such as an inflammation of the sensible sole, frog, and lamina of the foot; or perhaps in the ligaments of the coffin and small pastern joints, &c. In short, if we examine and reflect upon the structure and functions of those parts, we shall see, that they are continually kept in an unremitting state of exertion; and the action which produces an unequal distribution of the weight, will undoubtedly produce a lameness, easily to be mistaken for a rheumatism, as the inflammatory symptoms will often subside, without the farrier's assistance; but there will remain a chronic lameness, for weeks, or perhaps months, generally owing to the mismanagement of the original accident; and to save the practitioner's ignorance, the disease goes under the name of rheumatism.

If horses and other animals are subject to rheumatism, it will be found to proceed from an inspissated mucus left upon the fascia of the muscles, occasioning pain when they move.

The grand difficulty lies in ascertaining the seat of this disease; however, the shoulders and hips are the parts most commonly affected with it, and it is often so deeply situated in those parts, that neither the sight, nor even the touch, can enable us to determine, nor to distinguish it from any other lameness. But if a horse goes lame without a visible cause, accompanied with a wasting of the limbs on the side affected, it appears so evident, as not to leave any doubt of its being a rheumatism.

*The Cure* must be began by taking a little blood, and rubbing the parts twice a day with spirits of turpentine, or blistering the decayed parts, allowing them to discharge for a considerable time; if these fail, no method would then be attended with so probable a success of a radical cure, as the actual cautery, made very small and round pointed, so as to be introduced very deep into the muscular parts; a few doses of purging physic will be of some service, particularly if it pro-

ceeds from any strumous humours, or a tendency to an ulcer; in the interval of purging, give one or two alterative balls every day, composed of antimony half an ounce, and calomel fifteen grains; the same dose may be repeated every day, and continued until the desired effect is obtained, taking care to keep the animal well clothed, with a great deal of gentle exercise.

This is another case in which warm bathing would be extremely beneficial, if it could be provided for horses with as little trouble and expense as it is done for the use of the human subject. After the treatment above recommended, it will be advisable to turn out the animal to grass; for which, a salt marsh will be preferable to any other; but this is recommended as a last resource only.

RIDING. See HORSEMANSHIP.

#### RIDING A TROTTER MATCH.

The method of riding a trotter is to sit as close down to the saddle as possible; by which I mean, you are not to rise in the stirrups, nor stand in them; but, taking a deep hold with the muscles of the thighs, sit as close and still as the action of the horse will permit; and the faster he goes, the less you will find your seat disturbed. The stirrups must not be too short, for you are never to bear more than the weight of your toe in them, and the rapidity of the horse going forward will give your body a little backward inclination, and your legs a little forward; for you must be mindful not to bring your legs too near him, lest he should bring his haunches forward, which might cause him to gallop.

The next consideration is, to know the manner and trim of the horse; for, since horses contract habits as well as men, at such times as you want their utmost exertions they must not be put out of them. Therefore, a man will ride a trotter to better advantage after he has been used to him, than he will the first time: accommodating yourself to the horse's manner, you sit still, and give him whatever aid or support he requires; carrying your hands low, you encourage him to extend himself to the utmost, and your judgment is to discover when he over-rates himself as much as will, if not prevented, certainly cause him to gallop.

This requires some skill, for otherwise you would be sure to make him gallop; to prevent him, you must increase your pull, but keep your hands down. Were you to raise your hand one quarter of an

inch to increase your power, you would cause the horse to gallop. If you find you have not sufficient strength, rather than raise your hand, you may press your feet forward in the stirrups, to give effect to your pull; but closing the legs, or raising the hand, in this situation, would immediately cause him to gallop. A horse is as liable, nay, more likely, to gallop at times, when he is not near at speed in the trot, as when he is at over-rate, and this is when the jockeys say he is not settled; that is, when his haunches are too much under him, and his over-eagerness to get on will not slacken the haunches to give the shoulders the lead.

These are awkward situations both for rider and horse, and they are rendered more so by the clattering of accompanying horses; the animation of the company so increases the horse's eagerness, which quickens the haunches, already too forward, that it requires the greatest skill to prevent the horse from galloping, and more so to settle him to the trot. Were you to ease your hand to give the shoulders liberty, the forwardness of the haunches would force the shoulders to gallop; if you pull at him, you increase your disorder, by pulling him together when he is already too much united, and risk his galloping; if you raise your hand, or close your legs, he is sure to gallop. You have, therefore, to act with the greatest caution and delicacy, by keeping your hands down, and preventing the propensity of the shoulders to lift into the gallop; you must not be angry or impatient, because your nerves would be thereby affected, which communicates to the horse, and he becomes more impatient, which prevents him from disuniting and extending himself; but if you are patient and cool, the restriction of the hand, mild and soft, the horse will soon slacken his haunches, drop his head, and extend himself. This done, you must be careful that no unsteadiness in your hand or seat creates the disorder again. The generality of trotters, when they extend themselves, or as they term it, *settle to it*, take a steady support from the hand; this must be permitted, and the hand kept firm and still, that the horse may have a dependence on it. He will frequently refresh his mouth, by yielding his nose, or moving his head, and then take a support again; whatever is accommodating to him may be allowed, so that it has not a tendency to make him lift before or behind, gallop, or abate his trot. When a

horse is true on his legs, you may encourage and urge him to do his best, but if he over-rates himself (which you will feel and know by practice) he must fall, or gallop to prevent it; unless the rider, at the instant he perceives it, saves and prevents him, by the method I have before related. When a horse's powers are unequally distributed, which happens from different causes; from nature, when the hind quarters have greater liberty than the fore, or the fore than the hind; from habit, by bad riding, when a horse is suffered to trot before and gallop behind, or gallop before and trot behind, they are then apt to lift or hitch when pressed or tired. You cannot in these situations urge them on, for fear of making a complete gallop of it; and the lifting and hitching are liable to dispute, the one party denying it to be a trot, the other persisting he did not gallop. In these situations, cool and patient endeavours will effect your purpose, and get your horse true in his trot, preferable to any other measures. You must not flurry a horse on any account, for that will surely unsettle him; and when settled, your seat must be as steady as possible, and your hand kept down, and attentive to correct every propensity to lift, hitch, over-rate, gallop, and the like. And whenever you feel these propensities, you must check them with the greatest nicety; for these checks certainly retard the horse's speed, consequently you must apply no more than just sufficient to prevent his galloping. Therefore, all the operations of the hand must be low, to keep the horse down, as they term it.

From these remarks, a person by practice may the sooner acquire the art; but, remember, a person must be a good rider to ride a match, whether galloping, or trotting, to the best advantage; and to ride well requires practice; for the theory is only the knowing how it should be done, and may want the ability to do it; but knowing the theory will certainly assist your practice.

**RIDING SCHOOL** is a convenient receptacle, with every accommodation for riding, where the young of both sexes are taught to ride by proper masters.

**RIFLE.** A short gun for ball-shooting, the inner surface of the barrel being grooved.

“Rifles (says Baker) throwing to the right or left is sometimes owing to the trigger pulling too hard, and at other times, to the man throwing his head too

far over the centre of the stock. The sword or bayonet, when fixed on the barrel, will be liable to attract the sight towards it, which will give a cross sight: in taking aim, the practitioner should guard himself particularly against this, or he will be much deceived at the intended object.

The alteration I have made in the false breech, at the breech-end of the barrel in rifles, by making a large deep hollow, will conduct the eye in a straight line to the sight, and will be found useful in preventing a cross sight. The importance of these improvements will be sufficiently obvious, and I have no doubt, when carried into practice, will meet general approbation, and be found very useful to the service in general.

By way of ascertaining whether a rifle carries to the right or left, I tried the following method, and the result of various experiments was perfectly satisfactory. I constructed a number of boards, to form a target, in a similar manner to a plate-rack. I placed twelve of these boards, half an inch thick, and separated one inch from each other, at the distance of one hundred yards, and as the ball passed, I carefully marked its direction. With a rifle which has thrown the ball from the straight line, I have found it pass through the target, as above constructed, in calm weather, one inch more on one side on the outward board than the one in the centre, where the ball, from a perfect rifle, had previously entered. I have repeatedly tried this experiment, in all weathers: and am convinced that my former opinion was perfectly correct, in stating, that the wind has a powerful influence on the flight of the ball, and will cause it to fly from a straight line, even though the piece be perfectly true.

If the rifle is found to throw to the right, the back sight should be drove to the left, and the front sight to the right; both of which are left loose for that purpose; if it throws to the left, move the sight contrary, as above, till the man who uses it finds it right. I do not approve of the sights being moved, after once set straight for the man that practises it.

The trigger should not draw too hard, as that will alter the direction of the rifle in firing. A rifleman, to ascertain when his trigger pulls too hard, is to suspend the trigger of the rifle on the fore-finger of his right hand, with the muzzle downwards, with the lock on full cock, (taking care the piece is not loaded, as that would

be very dangerous,) which should just bear its own weight; and if it requires considerably more than the weight of the piece to pull off the trigger, it is too hard, and will take the rifle out of its right direction when fired. The same rule will do to try the locks of muskets by; and the same expedient should be resorted to. I have seen many muskets where the trigger has drawn so hard as to require considerably more than their own weight to draw them off; and have often wondered how soldiers contrive to fire them at all; and particularly how they keep pace with others that will not bear their own weight when suspended on the trigger. What must be the exertion of the one man to the other, whose trigger draws so easy! I do not allude to hair triggers, but the triggers with common pull, as now used by the ninety-fifth regiment. The gun should neither be over heavy, nor too light; as the extreme of either would prove equally disadvantageous: in the one case, the gun might be made so heavy, that, were the trigger to bear the weight of it, it would cause too great exertion; and, in the other case, if it be made too light, by the same rule it would be very unsafe. The rifles of the ninety-fifth regiment are nine pounds and a half each; and the locks have a fly or scape in the tumbler, to prevent the sear catching at the half-cock, which will frequently happen, if the lock pulls as it ought to do without it; rifles requiring a much lighter pull at the trigger than muskets.

In letting the cock down from full to half-cock, the following directions should be particularly attended to: the thumb of the right hand should be on the top of the cock over the flint, against the cock-pin that holds in the flint: hold it back; with the fore-finger of the right hand draw the trigger, and let the cock gradually down towards the pan until it has passed the half-cock; then draw it back into the half-cock, which will be easily ascertained by hearing it click into the half-bent or catch of the tumbler. The locks of rifle pieces have in general a fly or scape in the tumbler of the lock, which is called a detant, to prevent the sear catching at the half-cock, which keeps it from going into the half-cock until it is let down, and drawn back as before mentioned; and consequently requires particular attention. Indeed the locks of all fire-arms cannot be too carefully noticed, nor the method I have suggested be too minutely practised; as I have often found

the sear catch on the half-bent of the tumbler instead of going into the bent, which makes it very dangerous; as a shake of the piece, or dropping the butt on the ground, would let it off. Such a mistake has in a great degree induced the report of a gun going off at half-cock; and particularly the lock of soldiers' muskets, which are apt to catch on the half-bent of the tumbler, if not let down and drawn back as before mentioned. This arises from the half-bent and sear nose being left too wide or too thick, which is frequently the case, but more especially with the locks of muskets. I am not an advocate for the use of hair triggers, as they are apt to get out of repair, and without great care become dangerous. If the locks are made to act as before mentioned, there will be no occasion for them.

To take a true aim with a cross wind, I recommend the practitioner to make some allowance, as I have ever found that the surest method. Some people fancy the folding elevating sights most eligible: but I confess I have little opinion of their practical utility, as the joints of the sights will work loose from wear, so that there will be little dependence in the truth of them. The sight for the greatest range may be up, when a shot at a shorter distance may offer: in this case the man, not perceiving it, would be much deceived in taking his aim; and will require the face to be removed from its stationary place on the stock, to enable the eye to pass over it: thus he will be doubly deceived, as he will have no rest for his cheek. I have found it a more certain way to make allowance in the elevation, rather than to move the face from its stationary place off the stock, to allow the eye to pass over the folding elevating sights, for three hundred yards range. In trying guns I have frequently been deceived by folding elevating sights; for which reason I rely always on one sight, and consider that much more to be depended upon, at all distances. Its shape on the top should represent a sphere of a circle, with a small notch in the centre, so as to admit of the light on each side of the front sight, which forms itself to the eye better than any sight I have ever yet tried. The back sight should not stand too near the lock; as it will be liable to be filled with filth from the smoke from the pan of the lock, which will be a great denial to taking a true sight through the small notch. The sight cannot be too much simplified, as the object is more

easily obtained ; and if a man cannot measure his distance with his eye, all the folding, elevating, or telegraphic sights so wonderfully eulogized, will never realize his expectations ; and though perseverance may accomplish much, he may rest assured he will eventually discover his error. One of the principal sciences in shooting is, for a man to measure his distance correctly before he shoots ; and, if he cannot do this, all the sights that can be added will never make him a good shot with a rifle, or indeed any other piece. As I have said elsewhere, this may easily be accomplished by adopting the method I have suggested, and by adhering strictly to the rules laid down for judging distances.

Among other new-fangled terms for sights, there is one called the *dioptra*, or telegraph sight ; but of which I entertain a poor opinion. However, of this I am certain, that whilst the man is taking his aim through this *famous* invention, I could shoot him three times over. From the description of it, I consider it both cumbersome and troublesome, and very liable to be easily displaced. Neither the French, Germans, nor Americans, ever use such a ridiculous *advantage* as it is called. They use one back sight, which is indeed most certain ; and the front sight should be placed as near the nose end of the barrel as possible, and not, as I have occasionally seen them, two or three inches off ;—this could never have been invented by a *practical* gun maker, or even by a practical rifleman.

A rifleman should first fire from a rest, at a short distance, to ascertain the straight line of his sights ; after which he should ascertain the elevation of his rifle at point blank ; by which means he will elevate or depress, according to the distance he is from the object he fires at. A young rifleman should never accustom himself to fire from a rest after he has ascertained the nature of the sights, &c. but should practise the best position to insure steadiness. Firing at a target fixed against a bank of earth, sand, or chalk pit, has given me a much better opportunity of correcting errors, than firing at a small target alone in the middle of an open field. To ascertain the exact elevation or depression of a ball, place a small object either above or below the bull's eye, or centre of the target ;—by firing at various distances, the elevation or depression of the ball will be perceptible, and, by taking aim accordingly, you will obtain the

greatest accuracy. I suggest these hints to the young practitioner ; and strongly recommend him to embrace every opportunity to practise ; to make remarks on every variation that occurs ; and, by continually noticing the deviation of the ball from its intended object, he will ascertain with precision, and be enabled to rectify every error that occurs, till at last he becomes a good shot.

I wish to caution the rifleman never to be in too great a hurry in loading and firing. I have found one shot in a minute as much as I could fire to keep myself steady, and to perform every motion methodically ; and let him rest assured, as a general principle, that loading properly is much more advantageous than loading expeditiously.

When the sun shines strongly in the face, the brim of the hat is a great protection, as the rays are too powerful for the eyes, unless shaded with something. In ramming down the ball, the air will sometimes force the powder into the touch-hole very hard, which will occasion the rifle to hang fire, or flash in the pan, and not fire the powder in the barrel, particularly in joint or patent breech barrels, as the narrow chamber at the bottom of the patent breech is forced by the powder and the air which the ball drives before it so hard, that the rifle will hang or miss fire more than it will with a plain breech.

To prevent hanging fire, put a picker, made for that purpose, into the touch-hole whilst loading ; shut down the hammer on the picker, or the air will blow it out ; when loaded, take out the picker, prime, and with the picker force a little powder into the touch-hole. Be careful not to prime too full, as it will prevent the hammer going down, and occasion the prime to be lost, or the damp to get to the priming ; which will make the rifle hang or miss fire. A pin or small feather will be equally effective to stop the touch-hole when not provided with a picker.

I have been credibly informed, ‘ that the balls used by the Turks and the Arabs occasion much more terrible wounds than those used by European troops : they have attached to each of them a pedicle of iron or copper, which is united with the lead when cast. The iron wire, which is about an inch long, enters into the cartridge, and sometimes unites two balls together. They are besides ragged, and of a larger calibre than those of our pieces\*.’ I do

---

\* M. Larrey, in his “ Memoirs of a

not pretend to dispute the authority—but I much doubt the effect. In pieces of ordnance, the bar or double shot, and the chain-shot, may, no doubt, do much more execution than a common ball, but in rifles and muskets, I am quite satisfied that no ball can carry true, unless it fits the tube, as I have frequently enforced.

It has always been considered that three-fourths, or a whole turn in the angle of a rifle in a barrel three feet in length, was the best for throwing a ball to a certainty. This mode of rifling is practised by the Germans, French, and Americans; and all the foreign rifles that I have ever yet seen are rifled according to that principle; and several English gunmakers are firmly of opinion, that one turn in four feet is the best angle possible. With these angles of rifle I never could fire at a long range to any degree of certainty. If I apportioned the powder to make it range at three hundred yards, I found the ball go very random; and from this I judged that the balls tripped over the top of the rifle, which caused it to fire as random as a common musket. In order to find out the cause of this evil, I rifled a barrel one turn in four feet; and, on trial, found that the nearer I came to the straight line, the more true and further I could range. I then cut it to one foot, one quarter turn, and found I could fire more true at a short distance than I could when more angle in the rifle. From this conviction I made a barrel two feet six inches, and rifled in one quarter turn. The experiment succeeded to my most sanguine expectation. I was perfectly satisfied, that I could range further, and more true, than in any previous trial, and with less elevation. In loading also, the friction is not so great, and the ball is not so much impeded in coming out of the barrel, by the angle in the rifle more approaching to the straight line."

**RIG.** A horse is so called upon whom the operation of castration has been ill performed; by leaving one of the testes, or so much of the epididymis, behind, as enables him to become exceedingly teasing and troublesome to mares, either in the field or stable.

**RING-BONE.** A large swelling on the lower part of the pastern, which generally reaches half way round the fore

---

Military Surgeon:" in which he states that many soldiers came under his direction, wounded with balls of this description.

part, and, from its resemblance to a ring, has an affinity to a bone spavin; and, for the most part, proceeds from the same cause. The external cause of a ring-bone is often a strain in the pastern, from hard riding on dry roads; or owing to the pastern having been wrung in deep clayey roads, either in travelling or at grass. These often produce ring-bones. Yet some horses are naturally subject to ring-bones, especially those that are large and bony about the pasterns. When a ring-bone appears upon a clean-limbed horse, it is seldom so dangerous as when it happens to horses that have large bones, and are fleshy in those parts; for when the swelling is removed, the stiffness often remains.

A ring-bone is always easier to cure when it appears distinctly round the pastern, than when it spreads downwards towards the coronet; for then it is apt to affect the coffin joint, if it does not derive its origin from some strain or defect in that joint originally; in which case the cure will be uncertain, and sometimes impracticable, when a callosity is produced under the round ligament that covers that joint, and even when it happens more externally; it proves also dangerous, when it unites with or spreads the ligamentous substance that joins the hoof to the flesh; it is apt to turn to a quittor, and in the end to form an ulcer under the hoof. A ring-bone that rises on the pastern is easily cured when it does not run down towards the coronet.

Gibson says, the ring-bones that appear on colts and young horses will often insensibly wear off themselves, without the help of any application; but when the substance remains, there needs no other remedy besides blistering, unless when, by long continuance, it is grown to an obstinate hardness, and then it may require both blistering and firing. The swelling may proceed only from the tendons, which sometimes is not easy to be distinguished from a true ring-bone, except only that a true ring-bone is less painful, unless it proceed from the coffin-joint. In this case, blistering alone generally proves successful; and it is to be renewed two or three times, according to the urgency of the symptoms. But in a true ring-bone, where the substance is hard, like a piece of flint, and altogether insensible, and without pain, firing is the only thing to remove it.

Gibson, in order to fire a ring-bone successfully, advises the operation to be

performed with a thinner instrument than the common one ; and that the lines or razes be made not above a quarter of an inch distant, crossing them obliquely somewhat like a chain. He directs us to apply a mild blister over all, and when quite dried up, and before the hair is grown, to lay on a charge of yellow rosin and bees-wax, &c. melted together and

spread over the pastern-joint, covering the whole with flocks, or with the stuffs of an old saddle. As soon as the horse has rested two or three days in the house, he advises us to turn him out to grass in some dry smooth pasture. The same method, he says, is to be followed when the ring-bone rises towards the coronet, or coffin-joint.

**ROACH** is a handsome fish either in, or fresh out of, the water ; it inhabits many of our deep, still rivers, affecting, like others of this genus, quiet waters. It is gregarious, keeping in large shoals. It has a small head, a leather mouth, which is round, and also small, with the teeth in the throat ; large eyes, the circle of which resembles gold colour, and the iris red, particularly whilst in perfection, as they may also be known to be by the smoothness of the scales, which, when out of season, feel like the rough side of an oyster shell ; the side line bends much on the middle, towards the belly, and the tail is a little forked. It is so silly a fish that it has acquired the name of the water sheep, in contra distinction to the carp, who for his subtlety, is termed the water fox. The proverb of “ sound as a roach,” appears to be not peculiar to this country ; the French have the same idea, who compare people of strong health to their *gardon*, our roach, and yet this fish is not more distinguished for its vivacity than many others.

This fish is in little esteem, from the quantity of bones ; the flesh is, however, exceedingly wholesome, and the roe, which is green and boils red, peculiarly good. Soup made of this fish is excellent. There is a kind of roach in some ponds and standing waters that is very flat, having whitish eyes and fins, and the tail much forked ; it is supposed to be bred from the bream and roach ; they never grow large, and are good for nothing. Roach differ much in goodness, according to the rivers they are taken from, but none of the species are good in ponds ; in many of the streams they are taken of two pounds weight, but the preferable size for eating, are those of about half a pound, and, probably, were they not so common and numerous, would not be so much despised as they now are.

Walton speaks of the largest roach in the kingdom being in the Thames, where many have been caught of the weight of two pounds and a half ; and, in the list published some years ago, mention is made of one which weighed five pounds.

The roach delights in gravelly, sandy, or a kind of slimy marl bottoms, under a deep, gentle, running stream : in summer they often frequent shallows near the tails of fords, lie under banks among weeds, (especially when the water is thick,) under the shade of boughs ; and at, or opposite, the mouth of a rivulet, or brook that empties itself into a larger river, the best roach are generally to be met with ; as winter approaches, their haunt is changed to clear, deep, and still waters.

The roach spawns the latter end of May, (according to the Elements of Natural History, it produces upwards of 54,000 ova, feeds on aquatic plants and vermes, and is preyed upon by the larger fishes

and water fowl :) for, three weeks after spawning, they are unwholesome ; they recover themselves in July, and get good about Michaelmas, but are in their prime in February or March.

Many ways are recommended to catch this fish by angling. When in deep waters, near piles of bridges, flood-gates, &c. in hot weather, a May or ant fly is to be sunk by a little lead, within a few inches of the hook, near the sides of these posts or piles : this is to be pulled up very leisurely, a roach will generally attend the fly to the surface, there gaze on it for a moment, and then take it.

*Stern fishing* is by fixing a boat (for without, roach of any size are hardly to be caught) to the stern of a vessel returned from a voyage, whose bottom is foul and furnished with insects, which the fish greedily devour. The line should not exceed four feet, the float be within a foot of its top, and the rod very short ; the bait to be three or four gentles, and dropped close to the ship's sides, not allowing the bait to swim more than eight or nine feet : begin at the first of the ebb tide, and for two hours the roach will bite freely.

To London bridge, and among the shipping below it, numbers of roach return in June and July, after having been up the river to spawn, and many of them are taken by means of a strong cord, to which is fastened a leaden weight, more or less, according to the strength of the current ; a foot above the lead, a twine twelve feet long is joined to the cord, and to this twine, at convenient distances, are tied a dozen hair links, with roach hooks at their ends ; these are to be baited with white snails or periwinkles, taken whole from the shell ; the twine with the hooks is then first thrown in, that the stream may run it out its full length without entangling, the weight is then let down to the bottom, the fisherman holds the cord in his hand, and readily feels the biting of the fish, which is a signal to pull up the weight and line : frequently five or six, and seldom less than two or three, are taken at a haul, and they are, for the most part, very large : by standing in a lighter or lug boat, that is fastened to some vessel, this method can be best managed.

Some, in both pond and river, chew and throw in white bread, baiting with one large gentle, and fish six inches from the bottom : others, for winter fishing, when maggots (which are, beyond question, the best winter bait) are not to be had, use greaves from the tallow-chandlers, thus prepared : put them in cold water upon the fire, in pieces of about half a pound, let them continue until near boiling, when they will become white and soft ; the whitest are to be reserved for the hook, and the rest used as ground-bait ; the hook should be No. 6, and the bait either touch the bottom, or lie within one inch of it. Earth bobs and gentles, are famous winter baits, using boiled malt or fresh grains as ground-bait ; in autumn, roach will take white paste, on a hook No. 9 ; in summer, snails and flies, under water, for they never rise at a fly like the dace. In April, cadis, oak-worms, and small red-worms, the latter especially in windy weather.

The season for roach fishing in the Thames (in which, near Shepperton and Hampton, many have been taken above two pounds weight) begins about the latter end of August, and continues longer

than most anglers (of which the Londoners for roach, are perhaps the best,) choose to brave the weather. In the summer they live on the weed, and do not quit for the deeps until it becomes putrid, which depends on the drought or wetness of the weather, much rain hastening its rotting; the fishermen all along the river are at this time upon the watch, and the instant the roach move, sweep them away with their drag-nets; it requires, therefore, skill in the angler to attend to this critical period, or the objects of his diversion are by wholesale carried to Billingsgate.

The tackle for roach must be fine and strong: by some are recommended a rod not exceeding six feet, a line, somewhat shorter, of six hairs, and about two feet of gut for the bottom links, a swan quill float, and hooks No. 11 or 12, (although, if not made of stouter wire than those usually sold of those sizes, No. 9 or 10; roach rarely break the hook in the water, yet the beard of these very fine hooks is frequently broken at the time of being extracted by the fish's springing about, and their mouths being so bony;) the baits, gentles, red paste, boiled wheat, or malt: the gentles of a pale red colour, with a white one, are often taken both by roach and dace with great eagerness; red paste is also excellent. (The angler is cautioned to be provided with several sorts of baits, as these fish are capricious in their feeding, and, in the course of a morn or eve, will shun what they had just before taken, and, in a short time, again with avidity seize that, rejecting all others.) Great attention must be paid to strike quick. In using boiled malt or wheat, select those corns that are soft and plump; one is sufficient: put the hook into it so that the point may lie where it is burst and the white appears; the fish will be more readily hooked. The ground-bait should be boiled malt, with which some holes may be previously baited; if that mode is not adopted, whilst fishing throw it in, from time to time, sparingly.

The following method is mentioned as being more generally successful than any other. A rod, rather stiff, which will strike true, and in length, proportioned to the place where used; the line, a foot shorter than the rod, strong at top and tapering to the bottom, which must be fine, smooth, silk-worm gut, dyed brownish, or of a water colour; the hook No. 8; one small shot is to be put on the line, about ten inches from the hook, the rest (large) close together, four or five inches higher up, sufficient so to sink a swan quill float as that its top may just be discerned above the surface. When a spot is fixed on, plumb the depth, and the float is to carry the bait not more than one inch from the bottom, which must be level, the run gentle, and the water deep when clear, or in winter; at other times, when the water is coloured with rain, and especially if in the rain, the bait should swim from about three quarters of a yard to the depth of a yard and a half: if in a tide, or where streams rise or fall, the depth, by means of the plummet, is to be ascertained and observed as above directed. At the top of the swim throw in three or four balls of ground-bait, (about the size of an egg, and a pebble in each to sink them, and which is to be made with large wheat bran, enough sweet coarse flour to bind the bran, and scalding water; this

i to be so kneaded as to be sufficiently stiff to prevent its breaking in sinking to the bottom, and yet so as to fall gradually to pieces soon after it reaches it,) and care should be taken so to throw the balls as that the bait may rest as directly over them as possible. The bait is a grain or two of salmon's roe, or a small piece of red paste in imitation of it, (which is as good as the roe, and will continue on the hook a long time, if properly made, even if the fish is struck at and missed, and there be no cotton mixed with it.) A sharp eye must be kept on the float, and the least nibble is the signal for striking; if a full-sized roach is hooked, he should be played, for they struggle much; and, although many accustom themselves to a single hair line, yet, where the fish run large, it is not always to be depended upon. A landing-net is useful in getting out the big ones, and by drawing them two or three yards below where the ground-bait lies, there will be less disturbance to the fish beneath.

Should the water not be very clear, two hooks may be used, by neatly looping a piece of gut, two or three inches long, with a hook to it, close above the single shot, so that it may stand out from the line; bait it with gentles, and the lower hook with the paste or roe; and if they are shy, with a gentle slipped into the bend of the hooks, and a grain of the roe or paste upon the point.

Roach are also to be caught in warm weather with cadis and natural flies under water; and will, sometimes, in warm, close evenings, a little before sun-set, take an artificial fly at top, but then, a well scoured gentle must be placed at the end of the fly. In mild, cloudy weather, the roach will bite all day; in hot, morning and evening; and in cold, the middle and warmest parts of it.

Large roach, after having some flour thrown upon them, should (without scaling) be laid upon a gridiron over a slow fire; as they grow brown, a cut, not more than skin deep, is to be made along the back, from head to tail, and then replaced on the fire; when sufficiently broiled, the skin and scales will peel off, and leave the flesh perfectly clean, and very firm. The belly is then to be opened, and the inside will come away more cleanly than if water had been used before broiling, which washes away all the firmness and flavour of any fish. The sauce to them is anchovy and butter.

**ROAD-RIDING.** When persons are pursuing their business, pleasure, or recreation on the road, precise formality and attention to the strict rules of riding would interrupt their enjoyment, and divert them, in some degree, from attending to the various objects that present themselves, the conversation of a companion, or the delightful prospects continually opening to their view. Therefore, in this system of riding, thought and attention, more than regulating the pace and directing the road, are rarely indulged; and this, after due practice, becomes habitually instinctive. The small share of science requisite to direct the horse that is quiet

and good tempered, induces many to think it unnecessary to learn to ride. And here I shall observe, that those who have been taught the true principles of riding, and practised it till it becomes easy and habitual to them, can never depart from it so far as to render themselves conspicuously awkward, or in danger from the ordinary occurrences that may happen.

The military cannot adopt this ease and indifference, because the soldier's attention is always occupied. If the horse only walks he has an exact situation to keep, a file to cover, and preserve the line with the flanks; his ears must be atten-

tive only to the commands of his officer, and his hand have the horse in readiness at the instant to execute with precision. Thus the military are necessitated to ride with more formality than is pleasant or necessary for gentlemen on the road.

Though I admit, for the sake of ease, the participation of company and the surrounding objects, deviation from precise rules, yet I do not mean to vary the system or substitute another for the road.

I think there are several systems, which, though called by some good riding, would be very degrading and unbecoming gentlemen to imitate. For instance—the men who shew horses for the dealers, are generally thought to ride well. They must necessarily be men of firm seat and void of fear; but their only conception of good riding is, to make the horse go straight and as fast as they can. To display themselves and horse to the best advantage, they sit as stiff as possible, divide their reins, and place their hands low, and endeavour to keep the nose down, and drive him forward with the spurs. Many of their horses being, what is termed, raw; that is, but little accustomed to be ridden, and only in this awkward manner; would not shew to so much advantage, by any other method; but this method should not be a pattern for gentlemen.

The next description of riders I shall notice, are gentlemen's servants or grooms. From their occupation one would suppose these men would ride well, and without doubt some of them do: but how frequently do we observe the labour and difficulty others of them have to manage a quiet horse. Many of the spectators conceive the horse to be exceedingly violent and unruly, and admire the boldness of the rider; when, in fact, it is too frequently the unskilfulness of the horseman that occasions the horse to be so impatient and restless: for when a horse is well fed and little worked, many will shew an eagerness to get on; and if the rider has not a mild effective hand to restrain the horse, the harsh hand, though it checks, yet it irritates, and the horse becomes more impatient and restless under the severity of the hand. This frequently provokes the rider, and he applies the spurs, which make the horse more violent and ungovernable. I do not know but some gentlemen may be proud of displaying their horsemanship in this manner; they will only, however, draw the admiration of the ignorant, for nothing can

distinguish the horseman or gentleman so much, as the elegance, delicacy, and ease with which he makes the horse obedient to his will: not but there are violent, hot, and impatient horses, who will be restless under the best of hands—but the good hand restrains with mildness and ease, and the horse's temper by degrees cools and subsides, while the violent hand frets, provokes, and defeats its own intention.

The rudiments of the art being once known, when on the road, no more is to be applied than will, with the greatest ease, facilitate our design; and where you require no more of the horse than to perform the natural paces, he will walk, trot, and gallop with the greatest freedom. The rider participates the like ease or unrestrained liberty: so that road-riding bears the same analogy to military-riding, as military-riding does to manege-riding, laying aside all unnecessary restraint when we can perform to our satisfaction without it.

Let me explain what I mean by unrestrained liberty, lest those who have not confirmed the principles of riding by sufficient practice, may throw off their restraint too soon, and fall into errors, that might not only be awkward, but, under some circumstances, dangerous. The position of every part of the horseman is to be preserved, the same as in the military seat; but the restraint to be thrown off is, first that of the mind; for having nothing to perform but what by your former practice you can now execute, without a thought, your attention is amused by various other objects:—next of the body; for the exertions of the horse, in the manege lessons, are drawn from him by a similar exertion. In the rider, exertion now becomes unnecessary, since you require no more than the natural paces of the horse, performed with the greatest ease and freedom to himself; and your whole system becomes more relaxed, and falls into an easy flexibility, pleasant both to yourself and horse. But this ease or inattention is not to suffer unseemly habits to take place, such as the back or shoulders to get round, the hand to shake, the legs to dangle and beat against the horse's sides, or placed considerably forward to bear in the stirrups. These errors may, more or less, creep on a person who has not confirmed the principles by sufficient practice; but when habits of good riding are firmly established, the ease and liberty he assumes will not exceed propriety, risk his security, nor aban-

don or baffle the horse ; his hand will keep its situation and properties, though the body be turned to any extreme for the purpose of viewing, conversing, and the like. Nor will the body, by any freedom it takes, throw itself out of balance, nor take the liberty at a period, when it cannot be done with safety.

This freedom and ease, so desirable and universally admired, is affected by every person who is in the habit of riding, but with this difference ; some unite system with negligence and ease, and others negligence and ease without system.

This freedom and ease, which negligence will naturally fall into, I have known masters endeavour to inculcate before the rudiments and principles of riding. But, however specious and pleasing such a mode may appear to the pupil, I will be bold to say, it is beginning at the wrong end ; and if the pupil has not aptitude, which practice will improve, such a mode of instruction will never make a horseman.

Since the rider's ease and convenience is the principal consideration in riding on the road, it is admissible when the trot is extended to an unpleasant roughness, to ease the jolting by rising in the stirrups. This is so soon learned, that it scarcely needs a description, since none in the habit of riding, but actually accomplish it ; and it is generally the first thing the young untutored horseman aims at, though a ridiculous awkwardness frequently attends some at their first attempt, and many imbibe unseemly habits, which they cannot easily abandon.

Now, to ride with elegance and ease, the following remarks may be useful ; or at least, may caution you to avoid ridiculous habits. Let the trot be extended to such a degree, that the action of the horse may raise you considerably from the saddle, while the sitting becomes rough and uncomfortable. To attempt it before would be not only unseemly, but difficult : for the faster the horse trots the easier it is to rise. It is the action of the horse, and not any effort of your own, that should raise you. Then if you bring your body a little forward when the action of the horse raises you from the saddle, a greater portion of your weight will be received in the stirrups, by which you ease your return to the saddle.

Now the next remark I shall make on a subject which is so easily accomplished may be thought tedious by some, yet to others it may be gratifying. I have observed

that a horse leads with one or the other foot in the trot, the same as in the gallop, and the feet beat the time of *one, two*. The foot which the horse leads with, determines the one you are to rise to, and you cannot change the order if you would by rising to the contrary ; but, if the horse changes his foot, you are necessitated to change with him, till which, your time is broken, and you are disunited, so that you rise and fall with his leading foot ; which foot, beating the time of two, you rise at one, the leading foot being in the air, and fall at two, when it comes to the ground. Thus the horse renders it perfectly easy to you by raising the body and marking the time, which, if you do not counteract by any endeavours or efforts of your own, you soon fall into.

Beginners are apt to try this in a slow trot, in which the action of the horse does not sufficiently raise them, and they endeavour to raise themselves by the stirrups. This is labour instead of ease, and such are said, in derision, to ride faster than their horse. The rise and return of the body are to be smooth, even, and as regular as the beats of the feet ; if you, through inattention lose your time, you get bumped upon the saddle till you fall into it again. Though this is called rising in the stirrups, it is to be remembered that no great stress or dependance is to be made on them.

A person can rise to the trot without the assistance of the stirrup, but not with so much ease to himself. It is, therefore, to be used as such and no more. Thus, when the body is raised from the saddle, the feet have a momentary pressure in the stirrups, which subsides as the body returns to the saddle. If you make more use of the stirrups than this, you risk your own safety ; for I have observed, that an improper use of the stirrups occasions many persons to be thrown, and a horse shying, or suddenly turning round, would occasion such a disaster. The rising of the body is not to be accompanied by any motion of the arms or lifting the shoulders ; nor is the small forward inclination of the body to occasion any roundness in the back ; this is invariably to be hollow, not only for the seemliness, but for the safety of your person ; likewise the action of the body must not cause the legs to move ; some suffer their legs to swing backward and forward with the motion of the body ; but care must be taken to avoid all unseemly habits : the legs are certain to be in their

natural and most proper situation, if the stirrups hang perpendicular, and the ball of the foot resting on them ; from thence they are never to move, unless to apply the calves or the spur. And, though indifference and inattention may permit them to deviate a little, yet those who have confirmed the true principles by sufficient practice, never suffer them to remove beyond a certain medium, which otherwise would expose the seat to disaster.

The body must have no assistance from the bridle to accompany the action of the horse, the hand must be held steady, and the reins of that determined length which preserves a communicative correspondence between the hand and mouth ; and though the rising of the body diminishes the effective operation of the *appui*, yet still there remains a proportion according to the goodness of the rider's hand, and the quality or fineness of the horse's mouth ; for I consider the system of riding, which I am now treating on, to be the practice of gentlemen, in their daily recreation on the road, which, consequently, should be divested of every thing that is unpleasant and fatiguing. Therefore the horse should be properly broke, and not put to such extremes as would require an arduous support from the rider to assist his performance ; such as trotting-matches and racing. The horse then, rode at no greater rate than he can accomplish with ease to himself, will carry his head up and play upon his bit, and be as obedient to the operation of the hand and aids, as this system of riding can possibly require. From these remarks, I think no one can mistake wrong for right, which is all I think necessary to say under this head.

ROAN. See COLOUR.

ROARING. We take the liberty of quoting what has been said on the subject by Mr. Percivall, in his scientific, lucid, and excellent Lectures :—

“ Roaring (this gentleman justly observes) may be defined to be, a peculiar unnatural sound, made in respiration. To one whose ears are familiar to this sound, any attempt to describe it may appear supererogatory ; and to one who is unacquainted with it, no description can convey just notions of all the variations of it that occur in practice. We are not only told of *roarers*, but we hear of *pipers*, *wheezers*, *whistlers*, *high blowers*, and *grunters* ; a cant in common use among our horse-dealers and horsemen, of the

vulgar meaning of which no professional man should shew ignorance. And though these cases are often confounded in practice, and not seldom, I believe, are despatched without any discriminative investigation at all, still the veterinary surgeon ought to be prepared to encounter these monsters at all points ; and therefore I shall venture on an outline of the character of each of them, in relation to the degree and peculiarity of the sound, though I am apprehensive I shall but faintly trace those nice points of distinction, which the appellations themselves appear to demand.”

*Pipers*, according to Mr. Percivall, do not belong to the genus of roarers, but may be justly considered as one of the stages of broken wind.

*The Wheezer*, though admitted to be a species of roarer, is not so perhaps in the strict sense of the term, since there is every reason to believe, that the affection that causes the wheezing noise which the animal emits when labouring under this disease, is seated in the lungs. This wheezing differs from the loud sonorous noise made by other roarers, and may be compared to that painful difficulty of breathing which distinguishes the human subject when labouring under that disease called asthma. The wheezer differs also from the roarer, inasmuch as the wheezing is a common attendant upon rest, and consequently may be often heard in the stables ; in all cases, it is distinctly audible as soon as the animal is walked or trotted out.

*The Whistler*.—The note of the whistler is too well known to need any lengthened description in this place : it is a sibilation which resembles the noise made by “ the northern blast rushing through a crack in the window-shutter.” It appears to be produced by a continued rush of air through some narrow pass in the trachea or larynx ; it is seldom or never heard, therefore, in a state of quietude, nor is the common practical test of roaring infallible here : when this disease is suspected, the best mode to ascertain it, is to gallop the horse up hill. “ One well-marked instance of this variety of roaring (says Mr. Percivall) I have met with in the human subject : a young gentleman, an acquaintance of mine, who had suffered much from a violent attack of *cynanche laryngea*, used to fetch his breath so hard, though with more apparent, than actual, labour, in walking fast up hill, and with a noise so in unison with the pipe of the whistler, that, when I first heard him, I

turned myself suddenly round, under an apprehension that a horse of this description was approaching at full speed at my heels."

*The High-blower.*—A horse of this description draws his breath hard, under moderate exertion; he makes an unnatural puffing noise at every respiration, which a by-stander would suppose was produced by the nostrils. But there is reason to believe, that, in genuine cases of this kind, the impediment will prove to be in the passages of the head; whence the dilated nostrils, and the sonorous puffs from them, when the animal's breathing is accelerated.

*The Grunter.*—A horse, thus affected, utters deep-seated murmurs, or sounds that may be compared to the grunting of a hog. This noise in the breath is not always generated under ordinary exercise; it is often produced by a sudden respiratory effort, the effect of some unexpected event: a sudden application of the spur, while riding; or an unlooked for lash of the whip, while driving; will often call forth one of these ejaculations. This affection, however, must not be confounded with the occasional grunts of a horse whose bowels are distended with air or food, or whose body is loaded with fat for want of work, nor mistaken for those sounds which proceed from a tight collar: these are only temporary, and often arise under ordinary exercise, whereas, *grunting*, in the sense it is here meant to be understood, is mostly a permanent and irremediable annoyance, and is only produceable with laborious or violent respiration. "In my opinion (says Mr. Percivall) this a pulmonary disease—a sequel of inflammation. This species of roaring very often escapes observation."

The confirmed roarer utters his complaint more clamorously than any of these: he is so vociferous, when his respiratory actions are violently exerted, that he unequivocally proclaims, "in loud and insuppressible boations, his distressing malady to all around him."

For the purpose of producing that sound in the breath, which is the test of roaring, it is necessary, generally speaking, that the animal be excited to make a sudden or forcible respiratory effort. Nor will it be amiss here to observe, that it has been a question of late, whether roaring is an act of inspiration or respiration: some steadily maintain the old position, and say, that it consists in an expiratory effort; while others venture upon new

ground, and contend that it is an accompaniment to a violent inspiration. As frequently happens in like disputes, both parties may be in the right, and that the circumstances of the case only require to be examined to prove it; for instance, if the horse is a high-blower; or, in other words, if the impediment to the passage of air is seated in the chambers of the nose, the sonorous puffs we hear are so many expiratory acts; whereas, if the obstruction is in the trachea or bronchiæ, the roaring sounds are sighs or *inspirations*; and when the glottis is narrowed, and sometimes, indeed, when the trachea is, the noise may be produced both by the ingress and egress of air; then, however, it is generally loudest in inspiration. Any instantaneous shock or cause of alarm, hard galloping, especially up hill, and the excitation of coughing, are the common trials to which the animal is subjected to make him roar; indeed, the most ready mode of proceeding is that in vogue with our *copers*; which consists in making a feint to strike the horse upon the body with a stick or whip, and in doing it suddenly and unawares, and with as much earnestness as if you were actually going to knock him down, at the same time that you are holding him fast and short by the head with the left hand. Although these are perhaps the readiest expedients which can be adopted, yet absolute dependance cannot be placed on them: they are inconclusive; and the only satisfactory test must result from actual and continued corporeal exertion. The practice of putting suspicious horses in harness, and making them draw heavy loads up hill, is, after all, probably the best trial that can be made of their wind. The simple act of coughing is a very indecisive test of roaring; and, now and then, the larynx being in part, or wholly, bony, coughing cannot be excited at all by compression of it; "though this to an experienced tact, the very inflexibility of it is a presumptive proof that the disease is present."

"In entering upon the *ratio symptomatum* of roaring, (says Mr. Percivall) I may observe that it bears an analogy to croup, both in relation to the proximate cause, and to the parts affected; but we must be on our guard not to carry this comparison too far, or it will lead us into serious pathological error; for, although I may broadly assert, that the proximate cause of roaring is founded in *cynanche trachealis*, the inflammation does not put

on that type which makes croup so formidable and dreadful a malady in the human being, nor is it confined to the years of immaturity. When roaring does happen in colts, it generally exists as a mode of termination of strangles: the catarrhal affection that accompanies strangles, now and then continues long after the wound in the throat is closed up, leaves the laryngeal membrane thickened and perhaps ulcerated, and thus lays the foundation of this disease."

However, not only catarrhal affections, many that are considered as inflammation of the lungs, terminate in roaring; and, in fact, the symptoms of this species of membranous inflammation are not, at all times, so diagnostically marked, as to enable us to steer clear of this error; and what renders cynanche trachealis infinitely more obscure and insidious in its attacks and course, is, that, in the majority of cases, the inflammation is of that mild chronic type which is apt to escape the notion of those to whom we must look for the first reports of ill health; and hence it is that so many roarers are continually met with, in whom nothing is known about the inflammatory action to which they owe their present malady. Hence then, since cynanche trachealis is the common forerunner of roaring, and that upon our knowledge of the one must principally depend our competency to treat the other, it may not be amiss to detail in this place, the symptoms by which its existence is indicated.

In the first place, it may be observed, that, under an acute attack of cynanche, the horse breathes short and quick, but, at first, generally with more pain than embarrassment; he emits sudden and often sonorous puffs from his tense and dilated nostrils, and, at every inspiration, exposes to view, the septum, deeply imbued with its own blood: his pulse is small, hard, and frequent; he has paroxysms of coughing, occasional guggling or rattling in the throat, and defluxion of pus from the nose; while the lightest pressure upon the larynx, or grasp of the windpipe, very much annoys him, and induces the cough: added to which, he has the other ordinary concomitants of febrile commotion. In some cases, when the inflammation is at its height, spasms of the larynx come on, during the continuance of which, respiration is carried on with so much distress, that the animal is, every now and then, threatened with suffocation; or the breathing may become embarrassed from

a thickening of the membrane where it lines the glottis.

Did the disease generally manifest itself in this acute form, it would remove all doubt as to the nature and tendency of the case; but it approaches and creeps on in that insidious way, that the foundation of roaring is absolutely laid before it is discovered that the proximate cause, inflammation, has been present in the air passages; at least, so it is with the generality of cases. Were the animal, from the first, placed under the eye of a skilful practitioner (of which, by the bye, there are very few to be met with) he might perhaps be able to discover symptoms or signs that would excite suspicion of what was going on: such as an unusual protraction of, or a fresh attack very like, a chronic catarrh, accompanied with soreness about the throat, perhaps some rattling or guggling noise in it, and a hard cough; disturbance of the respiration and pulse—short wind; little or much purulent defluxion from both nostrils; and increased susceptibility of the trachea and larynx on compression.

The causes of cynanche will, of course, be such as give rise to catarrhal and pulmonary affections in general; indeed, it often turns out to be an extension or sequel of the former, and may exist as a precursor of the latter. But there is one fact connected with its etiology, which, if kept in view, will frequently throw much light on the nature of the case, and enable us to form in our minds, a pretty correct diagnosis; and that is, that a large proportion of these subjects are harness horses—horses whose necks have been rainbowed by the bearing-rein for hours together, whose larynges have been compressed, and tracheæ distorted, by this unnatural and constrained position of the head and neck. It may be also remarked here, that simple flexion of the pipe itself, from the forcible and continued incurvation of the nose towards the chest, has been known to produce roaring.

Mr. Goodwin, veterinary surgeon to his majesty stated to Mr. Percivall, that, during his professional avocations at St. Petersburg, his attention was especially drawn to several horses, who by himself and others had been declared to be roarers, in consequence of their having got rid of their complaint in the manege. These horses, it would seem, therefore, roared from unnatural flexure of the windpipe; and this distortion the Russian system of equitation, which consisted

in the continual elevation of the head, and projection of the nose, was well adapted to counteract, and in process of time remove. The inconvenience at first is only temporary; the intervals of relaxation give the parts an opportunity, for a time, of recovering their wonted tone and shape; but repeated and long continued acts of such violence may so enfeeble their elastic powers, that permanent deformity of the larynx or pipe may result, and the malady become irremediable.

Mr. Sewell very justly censures the practice of buckling neck straps, or throat-latches of collars and bridles, tightly: it is obvious, that all this is uncalled for and wanton mischief, not to add cruelty.

Mechanical injury, then, is one of the most frequent causes of roaring; and it may be either a *proximate* one, or it may be an *exciting* cause, as in the case of cynanche. It is said by some, that the practice of making horses cough, by compressing their throttles, is apt to induce roaring.

“Having thus far (says Mr. Percivall) considered the symptoms and exciting causes of cynanche, and examined one of the immediate or proximate causes of roaring itself, let us pass on to particularize, and endeavour to account for the origin of, others which dissection has discovered to us. Cynanche may terminate in a variety of modes, and in one or other of these terminations may be said to consist almost all the proximate causes of roaring that remain to be described. The most common effect of inflammation of the air passages, is a thickening of the lining membrane; which, if it happen in that part of it that lines the chambers of the nose, will give rise to that thickness and pursiveness in the breath in which consists the complaint of the high-blower. But the part where this increment offers the most impediment, and consequently creates the greatest inconvenience, is the glottis, the figure of which is very sensibly diminished by the morbid thickness of its lining; and thus is produced roaring, or confirmed roaring, or, if the opening be much contracted, whistling. Though the calibre of the trachea may be also equally diminished by this interstitial deposit into its membrane, it admits of some doubt in my mind whether this, of itself, can be adduced as a proximate cause of roaring; but if the same deposition pervades the bronchiæ, it may either be productive of thick wind or of wheezing. In horses in

whom this state of parts has existed long—probably several years, the membrane, in consequence of undergoing a gradual organic change, assumes a variety of morbid aspects: it may be found simply thickened, or thickened, opaque, and white; or thickened and indurated, or corrugated, or reticulated, or tuberculated, or ulcerated: these last alterations, however, may proceed from another source. We now and then hear of cases, of most of which I am inclined to think that this is the pathology, that become roarers by *metastasis*: Mr. Coward, veterinary surgeon, Royal Artillery, related to me one of a horse of his own, in whom extensive tumefaction, and suppuration of the jugular vein, followed the operation of venesection, which was succeeded by abscess of the parotid gland, and terminated by disease of the larynx and permanent roaring.

The next morbid appearance met with, in point of frequency, is a band or distinct layer of adhesive matter, which is thrown across, or adheres to, some part of the larynx or windpipe. The situation and disposition of this solid effusion vary much: sometimes a band is simply formed across the passage, or that is joined by another, generally coming from the back parts by which the canal is divided into two or three passages; at other times the deposition is seated in the cellular interstices between the muscular band and the rings, so as to protrude the former, and thus narrow the main conduit. So that the adventitious substance here has not the disposition, nor does it put on the appearance, of that found in croup. This state of parts is also productive of confirmed roaring.

Tumours of any kind seated within, or in the vicinity of, the air passages, may, by partial obstruction or compression of them, prove to be causes of roaring. What is most commonly met with, is an abscess in the throat that presses more or less upon the epiglottis; and this occasionally creates very alarming symptoms, and would bring on suffocation and death, were not the operation, termed *bronchotomy*\*, had recourse to.

---

\* “When the animal roars to that degree, that respiration, even in a state of quietude, becomes a painful or laborious duty, or that he is threatened with suffocation, we have recourse to an operation which consists in making an opening into the larynx or trachea, and has been named *bronchotomy*.”

Another, and not a very uncommon cause of roaring, is a wasting, or, in some instances, a total absorption of one or more of the small muscles of the larynx.

A frequent concomitant, and occasionally a cause of roaring in old horses, is ossification, practical or complete, of the larynx: the thyroid cartilages commonly take on this change of structure; the others, however, in the advanced stage, often partake of it. But rarely do we meet with any bony accretion of the rings of the wind-pipe: now and then we detect osseous depositions in some of them; but I do not apprehend that any, or but little, inconvenience is thereby occasioned.

Doubtlessly there are other pathological varieties connected with the production of this disease. The chief considerations, however, are, that there must be contraction of the air passage, or partial obstruction in it somewhere; that, according to the degree of narrowness, and the situation of it, *cæteris paribus*, will be the kind and loudness of the sound; and that upon the power of restoring the capacity of the passage must depend the efficiency of our remedies towards removing the evil. With a view of ascertaining the degree of constriction necessary to the production of roaring, and of watching the symptoms of pain or uneasiness evinced by it, I passed a ligature of broad tape around the windpipe of an ass, about one third of the way down the neck. The tape was first drawn with moderate tightness, and the animal roared when made to trot; the pipe was then compressed to about half of its natural calibre, and the animal whistled: in both states the sounds were loudest in *inspiration*. At length, I drew the ligature as tightly as possible; in about a minute afterwards the animal, after having staggered about much, fell, struggled violently, and, apparently in great agony, expired in a sudden convulsive throw of the body upon one side, about two minutes after he had fallen. I found the membrane of the windpipe reddened and covered with frothy mucus: the passage was *not* completely obliterated: I could still pass a crow's quill through the constricted part of it."

Mr. Coleman has asserted, in his Lectures, that roarers are sound winded horses; and so far as regards the healthy state of their lungs, there is little doubt but this is the true state of the case; yet this amounts to nothing, since it is a fact very well known, that roarers are always

more distressed in the chase than sound horses; and that they cannot bear to be pressed up hill. Not only are sound lungs very essential to a full and healthy respiration, but that a clear and uncompressed passage is also absolutely necessary to it; and that, however disproportionably large the calibre of the trachea may seem when contrasted with its narrow entrance, the glottis, a very trifling contraction of the former will create noise enough in the breath to convince us that there is a degree of embarrassment in the performance of respiration.

"Moreover (continues Mr. Percivall) I shall now shew that the lungs themselves may be the *seat* of roaring. Some years ago, a horse was treated by my father (who is the senior veterinary surgeon of the regiment) for violent roaring. The neck was repeatedly blistered; it was also fired, but no relief was given. So painful was it to hear this animal roar, when he was even led out of the stable, that bronchotomy was tried, but without benefit. At length the animal suffered so much from pain and distress in breathing, that, being in that condition useless, and found insusceptible of relief, he was destroyed. There was detected no thickening in the membrane—no disease whatever, in fact, of the larynx or trachea; but the lungs were hepatized throughout their substance, and the smaller divisions of the bronchiæ, in many places, so compressed, that they were hardly pervious. I know that this is not reconcilable with the opinions of the day; and therefore I set the greater value upon it: it is a case also that is admirably calculated to silence the trumpery of those who are continually persuading people that *they can cure* roaring horses.

Let us now pass on to the treatment of roaring. Some of my professional contemporaries have contended hard for celebrity with the obstacles that are encountered in this alluring field for experimental research; but they would have spared themselves much labour if they had (and it is generally the nearest road to a cure, after all) directed their investigations vigilantly, but patiently, to the *cause*, instead of the removal, of the disease. Which of them, I should like to know, can attenuate a thickened and indurated membrane?—or, which of them, by tying up a horse's head, and confining it for a twelvemonth in that position, can remove an organized band that crosses the passage!—in a word, which of them can pro-

ceed, *secundum artem*, to cure a disease, of the nature of which he, by his own confession or silence, is either doubtful or ignorant?

When a roarer is brought to us, then, it behoves us to take every means in our power to ascertain the special nature and stage of his disease; to which end, we ought to inquire narrowly into the history of the case, and make ourselves acquainted with every little circumstance connected with it, before we proceed to examine the horse himself; and in doing this, we must take care to attend to the sound that is uttered. Having formed our diagnosis, the treatment to be pursued will naturally present itself.

If it be a case in which deformity of the windpipe can be felt, and there appears reason to believe that it owes its production to forcible innovation of the neck, the continual elevation of the head and the confinement of it by side lines, or the frequent biting of the animal, so as to project his nose forward, are means well worthy of trial: we must not forget, however, that the success of this experiment will depend upon the duration of the complaint; nor must we overlook any inflammatory action that may be present in the system, which might prohibit such measures.

This, I believe, is but rarely the state of the case, however; almost always, if the affection be recent, have we to combat with inflammation of an acute or chronic kind; the remedies for which, as it often assumes the catarrhal form, I need but recapitulate here. Venesection is generally required in the chronic stage; but, if the cynanche be active, it is imperiously demanded:—the frequent repetition of it too, is an excellent practice. Active purgatives—nauseating and diuretic medicines in the intervals—and blisters along the whole length of the windpipe, that are kept discharging, are to be resorted to: no rules can be laid down for their judicious use; that must be left to the discrimination of the practitioners. When active depletion is no longer admissible, counter-irritation often proves of great service.”

Having quoted the opinions of the ablest writer on the subject of roaring, which has yet appeared before the public, the reader will be thus enabled, I am willing to suppose, to place before his mind's eye as clear a view of the subject as it is possible at present to obtain; and will consequently be enabled to form an

opinion for himself, whenever a suspicion of roaring, in any of its forms, is entertained. By this proceeding, I by no means advise that he should attempt to act as his own veterinary surgeon; but be able to guard against the crude and fallacious notions of grooms and other ignorant pretenders. On the slightest suspicion of the approach of such a disease as roaring, I would call in the assistance of a skilful veterinary surgeon (and they are very rarely to be met with, as I have already observed) even if I had to procure him from the distance of one hundred miles.—Veterinary surgery, I consider as yet in its infancy, though there are not wanting pretenders enow to the science: men, calling themselves veterinary surgeons are numerously dotted all over the country, who profess to have been regularly initiated at the college, but whose gross ignorance of every thing like science cannot fail to become manifest, in the course of five minutes' conversation, to every man of common knowledge and common observation. These men, like attorneys, the moment a case is brought before them, begin to calculate on the best means of swelling up a bill; and in any disease or ailment out of the very commonest way, a man had better destroy his horse at once than place him under the care of such wretchedly illiterate and ignorant pretenders, but, at the same time, such voracious and insatiable corinorants.

As roaring is likely to be produced from low, wet, or marshy ground, and luxuriant pasturage, it may not be amiss here to observe, by way of elucidation, that horses thus summered, will become gross and fat; and, when taken up, are perhaps injudiciously managed:—their exercise and sweats may be too violent at first, and indeed a variety of causes may operate, under such circumstances, as well as under many others, to produce this not well understood disease.

ROCKINGHAM, FIRST CALLED CAMDEN. A bay horse, foaled in 1781, bred by J. Pratt, Esq. of Askrigg, Wensleydale, sold to P. Wentworth, Esq. who sold him to his royal highness the Prince of Wales; and was again sold, at his highness's sale, to T. Bullock, Esq. who sold him to Lord Barrymore.

Rockingham was got by Highflyer; his dam, Purity (own sister to Conundrum, Ranthos, Enigma, Riddle, Miss Timms, Maiden, and Rasselas), by Match'em; grand-dam by Squirt.

At Nottingham, August 3, 1784, Cam-

den won a sweepstakes of 50gs. each, for three years old colts, 8st. once round the course, (six subscribers,) beating Mr. Wentworth's bay colt, by Alfred, out of Rosebud; and Lord E. Bentinck's colt, by Highflyer. He was sold in the spring of 1785, for 700gs. to Mr. P. Wentworth, who changed his name to Rockingham.

On Monday, in the Newmarket second spring meeting, 1785, Rockingham beat Mr. O'Kelly's Serjeant, 8st. 4lb. each, B. C. Mr. O'Kelly staked 500gs. to 400gs.: 7 to 4 on Rockingham. On Wednesday, he won the jockey club purse, for four-year olds, 8st. each, R. C. beating Mr. Dawson's Roscius, the Duke of Northumberland's Denmark, Mr. Hale's Camel, Lord Grosvenor's Carlo Khan, and Mr. Panton's Pindar:—2 to 1 on Rockingham, and 7 to 2 against Roscius. On Saturday, he beat his royal highness the Prince of Wales's Hardwicke, 8st. 2lb. each, B. C. 300gs.:—5 and 6 to 4 on Rockingham, who was afterwards sold to his royal highness the Prince of Wales, for 2000gs. At Newmarket, May 11, at 8st. 7lb. he beat Mr. Dowson's Clayhall, 8st. 2lb. B. C. 500gs.:—5 to 2 on Rockingham. In the second October meeting, he was beat (for the first time), by Mr. O'Kelly's Soldier, 8st. 7lb. each, B. C. 500gs.—7 to 4 and 2 to 1 on Rockingham.

At Newmarket second spring meeting, 1786, Rockingham won 50l. for five-year olds, 8st. 6lb. and six, 8st. 12lb. D. C. beating Sir F. Standish's Delpini, 5 years old; Mr. Dowson's Clayhall, 5 years old; and Lord Clermont's George, 6 years old: 9 to 4 on Rockingham, and 5 to 1 against Delpini. At Ascot Heath, June 20, he walked over for a sweepstakes of 50gs. each, h. ft. for all ages, (6 subscribers,) four miles. In the same meeting, he walked over for a 50l. purse, for all ages. He was afterwards sold, at his royal highness the Prince of Wales's sale, for 800gs. to Mr. Bullock. At Lichfield, September 12, he won the king's purse, for five-year olds, 8st. 7lb. each, three-mile heats, beating Mr. Tetherington's Marplot, and Mr. Early's brown horse, by Tantrum. At Newmarket first October meeting, at 8st. 5lb. he won 70gs. for all ages, B. C. beating Mr. Wyndham's Guyler, 4 years old, 7st. 4lb. and Mr. Lade's brown filly, by Engineer, 4 years old, 7st. 4lb.—7 and 8 to 1 on Rockingham. In the second October meeting, at 8st. he won 60gs. for all ages, D. I. beating the Duke of Grafton's Oberon, 4 years old, 7st 4lb.;

Mr. O'Kelly's Soldier, aged, 8st. 6lb.; Mr. Wyndham's Ulysses, aged, 8st. 6lb. and Mr. Lade's Wilbraham, 6 years old, 8st. 4lb.—3 to 1 on Rockingham. Next day, at 8st 6lb. he won a subscription of 5gs. for all ages, B. C. (14 subscribers,) beating Mr. Wyndham's Drone, aged, 9st. 2lb.; Lord Grosvenor's Latona, aged, 9st. 2lb. and Mr. O'Kelly's Chaunter, 4 years old, 7st. 7lb.—7 to 2 on Rockingham.

At Newmarket Craven meeting, 1787, Rockingham won a sweepstakes of 50gs. each, h. ft. for all ages, four-year olds, 7st. 13lb.; five, 8st. 7lb.; and aged, 9st. D. C. (12 subscribers,) beating Sir F. Standish's Delpini, 5 years old; the Duke of St. Albans's Fox, 4 years old; Mr. Tetherington's Marplot, 5 years old; Mr. Wyndham's Drone, aged; Duke of Grafton's Oberon, 4 years old; and Mr. Lade's Pilot, 4 years old:—7 to 4 against Rockingham, 7 to 2 against Drone, 5 and 6 to 1 against Fox, and 7 to 1 against Delpini. On Monday, in the first spring meeting, at 8st. 3lb. he won 50l. for all ages, R. C. beating Lord Clermont's Collector, 5 years old, 8st. 3lb.; Mr. Wentworth's Cowslip, 4 years old, 7st. 9lb.; Mr. Wastell's Noodle, 5 years old, 8st. 3lb.; the Duke of Grafton's Patience, aged, 8st. 7lb. and the Duke of St. Albans's Challenger, 6 years old, 8st. 7lb.—5 to 1 on Rockingham. On Wednesday, he received 25gs. to withdraw for a 50l. purse, won by Lord Clermont's Woodcock. Next day, he won the king's purse for six-year olds, 12st. R. C. beating Mr. Dowson's Clayhall, 5 years old; Mr. Dawson's Roscius, 5 years old; and Mr. Hull's Quibbler, 6 years old:—5 to 1 on Rockingham. In the second spring meeting, at 8st. 12lb. he won the 140gs. subscription of 30gs. each, for all ages (nine subscribers), beating Mr. Wyndham's Skylark, 4 years old, 7st. 2lb.—40 to 1 on Rockingham. Next day, he won the jockey club purse, for horses, &c. 8st. 7lb. each, B. C. beating Mr. Wyndham's Drone, aged:—5 to 2 on Rockingham. At Guildford, May 29, he won the king's purse, for six-year olds, 12st. each, four-mile heats, beating Mr. Middleton's St. Valori:—4 to 1 on Rockingham. At Winchester, July 3, he won the king's purse, for six-year olds, 12st. each, four-mile heats, beating Mr. O'Kelly's Chaunter. At Nottingham, August 14, he won the king's purse for six-year olds, 12st. each, four-mile heats, beating Mr. Wentworth's Prince of Orange:—4 to 1 on Rockingham. At York August meeting, on Mon-

day, he won the king's purse, for six-year olds, 12st. four-mile heats, beating Mr. Hutchinson's Pitch, by Shark:—8 to 1 on Rockingham. On Thursday, he won one of the great subscription purses, for six-year olds, 8st. 10lb. and aged 9st. four miles, beating Mr. Wentworth's Verjuice, 5 years old; Mr. Garforth's Faith, aged; Sir W. Vavasour's Mark, 6 years old; Mr. Weatherill's Harlequin Junior, 6 years old; and Mr. Dawson's Roscius, 6 years old:—5 to 1 on Rockingham, and 7 to 4 on Verjuice, against Faith. On Saturday, at 9st. 7lb. he was beat by Mr. Hutchinson's Florizel, 3 years old, 5st. 7lb. the first heat, and was drawn; also distancing Mr. Wentworth's Cowslip, 5 years old, 8st. 6lb. for the Ladies' purse, four-mile heats:—From 10 to 20 to 1 on Rockingham. On Monday, in the Newmarket first October meeting, at 8st. 5lb. he won 50l. for all ages, R. C. beating Lord Grosvenor's Roundelay, 5 years old, 8st.; the Duke of Grafton's Oberon, 5 years old, 8st.; Mr. Wyndham's Ulysses, aged, 8st. 7lb. and Mr. Douglas's Macbeth, 4 years old, 7st. 5lb.—5 to 1 on Rockingham. On Wednesday, at 8st. 12lb. he won the 140gs. subscription, of 30gs. each (nine subscribers) beating Mr. Wyndham's Skylark, 4 years old, 7st. 7lb.—high odds on Rockingham. Next day, he won the king's purse, for six-year olds, 12st. R. C. beating Mr. Tetherington's Marplot:—6 to 1 on Rockingham. Same day, at 8st. 11lb. he won 70gs. for all ages, B.C. beating the Duke of St. Albans's Fox, 5 years old, 8st. 5lb.; Mr. Clark's Schoolboy, 5 years old, 8st. 5lb.; Sir F. Standish's Lepicq, 5 years old, 8st. 5lb. and Mr. Vernon's Flyator, 4 years old, 7st. 4lb.—4 to 1 on Rockingham. In the second October meeting, at 8st. 4lb. he won 60gs. for all ages, D. I. beating Mr. Vernon's Mufti, 4 years old, 7st. 4lb.—5 to 1 on Rockingham. Next day, at 8st. 13lb. he won a sweepstakes of 5gs. each, for all ages, B. C. beating Mr. O'Kelly's Scota, 4 years old, 7st. 7lb.—10 to 1 on Rockingham. The above were the only times of his starting that year. He was afterwards sold to Lord Barrymore, for 2500gs.

At Newmarket first spring meeting, 1788, Rockingham walked over for the

king's purse, for six-year olds, 12st. R. C. In the second spring meeting, he won the jockey club purse, for horses, &c. 8st. 7lb. each, B. C. beating Mr. Wentworth's Verjuice:—5 and 6 to 1 on Rockingham. In the same meeting, he (rode by his owner, 8st. 12lb.) beat Sir G. Armytage's Star-gazer, (rode by L. Jewison) 8st. 4lb. B. C. 300gs.—4 to 1 on Rockingham.

At Newmarket first spring meeting, 1786, Rockingham, 7st. 8lb. was beat by Mr. O'Kelly's Dungannon, 8st. B. C. 500gs.—2 to 1 on Dungannon. At Burford, in the same year, he was distanced in running against Mr. Tetherington's Marplot, and Mr. Dowson's Clayhall, occasioned by running on the wrong side of a post, when 6 and 7 to 1 on him. At Newmarket Craven meeting, 1788, he paid forfeit, viz. in a sweepstakes of 50gs. each, h. ft. D. C. won by Lord Grosvenor's Meteor. Also at Newmarket Craven meeting, 1789, in a subscription won by Sir Peter Teazle; which, with the above, were the whole of his performances.

Rockingham was afterwards a stallion, and covered at Bennington, near Stevenage, Herts, in 1790, 1791, 1792, 1793, and 1794, at 10gs. and 1g.; at Epsom, in 1795, at 8gs. and 5s.; at Clayhall, near Epsom, in 1796, and 1797 at 10gs. and a half; in 1798, and 1799, at 7gs. and 5s. He died in the autumn of 1799. Rockingham was the sire of the following winners, viz.: Mr. Panton's Cuddy Moddy and Patriot, Mr. Hammond's Portland, Mr. Wilson's Bennington, Mr. O'Hara's Miss Pumpkin, Mr. Darling's Mother Redcap, Mr. Jones's Young Rockingham, Mr. Cosen's Arabella, Mr. Williams's Euphrasia, Mr. Stapleton's Fair Susannah, Mr. Harris's Brother Redcap, Mr. Bettison's Beelzebub, Mr. Heming's Kill Devil, Mr. Fletcher's Logie o' Buchan, Mr. Coventry's Sacripant, Mr. Spencer's Tunbridge, Mr. Joddrell's Macclesfield, Mr. Payne's Sally, &c. &c. He was also sire of the dam of Mr. Benson's Dimple, &c.; of the dam of John Pratt, Swiftsure, &c. Susannah was the dam of Tom Wealthy, Master Betty, Tumbler, Ponteland, Yoxford, &c. Lavinia was the dam of Sylvanus, Fera-morz, &c. Mother Redcap was the dam of Mowbray, Pillowslip, &c.

**ROEBUCK.** The roebuck is the smallest of the deer kind known in our climate, and is now almost extinct amongst us, except in some parts of the Highlands of Scotland. It is generally about three feet long and two feet high. The horns are from eight to

DOE AND FAWN

## R O E B U C K

nine inches long, upright, round, and divided into only three branches. The body is covered with long hair, well adapted to the rigour of its mountainous abode. The lower part of each hair is ash-colour ; near the ends is a narrow bar of black, and the points are yellow. The hairs on the face are black, tipped with ash-colour. The ears are long, the insides of a pale yellow, and covered with long hair. The spaces bordering on the eyes and mouth are black. The chest, belly, and legs, and the inside of the thighs, are of a yellowish white ; the rump is of a pure white, and the tail very short. The make of this little animal is very elegant : and its swiftness equals its beauty. It differs from the fallow-deer in having round horns and not flatted like their's. It differs from the stag in its smaller size, and the proportionable paucity of its antlers ; and it differs from all of the goat kind, as it annually sheds its horns and obtains new ones, which none of that kind are ever seen to do.

As the stag frequents the thickest forests and the sides of the highest mountains, the roebuck, with humbler ambition, courts the shady thicket and the rising slope. Although less in size, and far inferior in strength, to the stag, it is yet more beautiful, more active, and even more courageous. Its hair is always smooth, clean, and glossy ; and it frequents only the driest places and of the purest air. Though but a very little animal, as we have already observed, yet, when its young is attacked, it faces even the stag himself, and sometimes comes off victorious. All its motions are elegant and easy ; it bounds without effort, and continues the course with but little fatigue. It is also possessed of more cunning in avoiding the hunter, is more difficult to pursue, and, although its scent is much stronger than that of the stag, it is more frequently found to make a good retreat. It is not with the roebuck as with the stag, who never offers to use art until his strength is beginning to decline ; this more cunning animal, when it finds that its first efforts to escape are without success, returns upon its former track, again goes forward and again returns, until by its various windings, it has entirely confounded the scent, and joined the last emanations to those of its former course. It then, by a bound, goes to one side, lies flat upon its belly, and permits the hounds to pass by very near, without offering to stir.—In this we see much the same sort of manœuvring as that adopted by the hare.—In the only part of Great Britain, however, where these animals are found (the Highlands of Scotland) they are seldom hunted by hounds, but occasionally shot ; and as they are very shy creatures, so the approach to them is rendered difficult.

But the roebuck differs not only from the stag in superior cunning, but also in its natural appetites, its inclinations, and its whole habits of living. Instead of herding together, these animals live in separate families—the sire, the dam, and the young ones, associate together, and never admit a stranger into their little community. All others of the deer kind are inconstant in their affection ; but the roebuck never leaves its mate ; and as the male and female conceive so strong an attachment for each other, they never afterwards separate. Their rutting season continues but fifteen days, from the latter end

## R O E B U C K

of October to the middle of November. They are not, at that time, like the stag, overloaded with fat ; they have not that strong odour which is perceived in all others of the deer kind ; they have none of those furious excesses ; nothing, in short, that alters their state : they only drive away their fawns upon these occasions, the buck forcing them to retire, in order to make room for a succeeding progeny ; however, when the rutting season is over, the fawns return to their dams, and continue with them some time longer ; after which, they quit them entirely, in order to commence an independent family of their own. The female goes with young but five months and a half, which alone serves to distinguish this animal from all others of the deer kind, that continue pregnant more than eight. In this respect, she rather approaches more nearly to the goat kind ; from which, however, the race is separated by the male annually casting its horns.

When the female is ready to bring forth, she seeks a retreat in the thickest parts of the woods, being not less apprehensive of the buck, from whom she then separates, than of the wolf, the wild cat, and almost every ravenous animal of the forest. She generally produces two at a time, and three but very rarely. In about ten or twelve days these are able to follow their dam, except in cases of warm pursuit, when their strength is not equal to the fatigue. Upon such occasions, the tenderness of the dam is very extraordinary ; leaving them in the deepest thickets she offers herself to the danger, flies before the hounds, and does all in her power to lead them from the retreat where she has lodged her little ones. Such animals as are nearly upon her own level, she boldly encounters ; attacks the stag, the wild cat, and even the wolf ; and, while she has life, continues her efforts to protect her young. Yet all her endeavours are often vain ; about the month of May, which is her fawning time, there is a greater destruction among these animals than at any other season of the year. Numbers of the fawns are taken alive by the peasants ; numbers are found out and worried by dogs, and still more by the wolf, which has always been their most inveterate enemy.

They were once common in England, and the old sportsmen gave names to the different kinds and ages, as to the stag :—thus they called it the second year a *gyrle*, and the third a *hemuse*.

The fawns continue to follow the dam eight or nine months in all ; and upon separating, their horns begin to appear simple and without antlers, the first year, as those of the stag kind. These they shed at the latter end of autumn, and renew during the winter ; differing in this from the stag, who sheds his horns in spring and renews them in summer. When the roebuck's head is completely furnished, it rubs its horns against trees in the manner of the stag, and thus strips them of the rough skin and the blood vessels, which no longer contribute to their nourishment and growth. When these fall and new ones begin to appear, the roebuck does not retire, as the stag, to the covert of the wood, but continues its usual haunts, only keeping down its head to avoid striking its horns against the branches of trees, the

## R O E B U C K

pain of which it seems to feel with exquisite sensibility. The stag, who sheds his horns in summer, is obliged to seek a retreat from the flies, which at that time greatly incommode him ; but the roebuck, who sheds them in winter, is under no such necessity ; and consequently does not separate from its little family, but keeps with the female all the year round.

As the growth of the roebuck, and its arrival at maturity, are more speedy than those of the stag, so its life is proportionably shorter. It seldom is found to extend above twelve or fifteen years ; and, if kept tame, it does not live above six or seven. It is an animal of a very delicate constitution, requiring variety of food, air, and exercise. It must be paired with a female, and kept in a park of at least one hundred acres. They may be easily subdued, but never thoroughly tamed. No arts can teach them to be familiar with the feeder, much less attached to him. They still preserve a part of their natural wildness, and are subject to terrors without a cause. They sometimes, in attempting to escape, strike themselves with such force against the walls of their inclosure, that they break their limbs and become utterly disabled. Whatever care is taken to tame them, they are never entirely to be relied on, as they have capricious fits of fierceness, and sometimes strike at those they dislike with a degree of force that is dangerous.

The cry of the roebuck is neither so loud nor so frequent as that of the stag. The young ones have a particular manner of calling to their dam, which the hunters easily imitate, and often thus allure the female to her destruction. Upon some occasions also they become in a manner intoxicated with their food, which, during the spring, is said to ferment in their stomachs, and they are then very easily taken. In summer they keep close under covert of the forest, and seldom venture out, except in violent heats, to drink at some river or fountain. In general, however, they are contented to quench their thirst with the dew that falls upon the grass and the leaves of trees, and seldom risk their safety to satisfy their appetite. They delight chiefly in hilly grounds, preferring the tender branches and buds of trees to corn or other vegetables ; and it is universally allowed that the flesh of those between one and two years old is the greatest delicacy that is known.

In America this animal is much more common than in Europe : with us there are but two known varieties ; the red, which is the larger sort ; and the brown, with a spot behind, which is less. But on the New Continent, the breed is extremely numerous, and the varieties in equal proportion. In Louisiana, where they are extremely common, they are much larger than in Europe, and the inhabitants live, in a great measure, upon their flesh, which tastes like mutton, when well fatted. They are found also in Brazil, where they have the name *cugacu apara*, only differing from our's in some slight deviations in the horns. This animal is also said to be common in China.

The roebuck, as we have already observed, was formerly an inhabitant of England, and not unfrequently seen on the wastes near

## R O E B U C K

Hexham, in Northumberland : as the breed became gradually more scarce, it was sought for with additional eagerness, and after enduring the united attacks of the dog and the gun for a few seasons, it at length dwindled into one solitary animal, which, nearly a century ago, was destroyed by Mr. Whitfield, of Whitfield, in that county.

Bewick mentions a roebuck, which, after being hunted out of Scotland through Cumberland, and various parts of the north of England, at length took refuge in the woody recesses upon the banks of the Tyne, between Prudhoe Castle and Wylam. It was repeatedly seen and hunted ; it frequently swam the river, and, either by speed or artifice, eluded all its pursuers. It happened that, during the rigour of a severe winter, being pursued, it crossed the river upon the ice with some difficulty ; and being much strained by its violent exertions, was taken alive. It was kept for some weeks in the house, and was then again turned out ; but all its cunning and activity were gone ; it seemed to have forgotten the places of its former retreat ; and, after running for some time, it lay down in the midst of a brook, where it was killed by the dogs.

The late Colonel Thornton, in his *Sporting Tour in the Highlands of Scotland*, mentions the roebuck :—When he was in the neighbourhood of Moy, he observes—“ I now adjusted my bullet gun, by which time the company came down stairs ; and at twelve I went out, intending to try for roebuck, which were said to be more plentiful and better preserved on this estate than in any part of Scotland.

I confess my patience had been so much tried before, that, though I proceeded, I thought my prospect of success very small ; but I took all imaginable pains, and saw one or a brace ; yet they were so deep in cover and sprang so quick, that my eye could scarcely follow them. Determined to go after black game, but still desirous of succeeding, took one cast more, and got the glimpse of another, at which I shot, and seeing one bound from the place, feared he was only slightly wounded, for I was certain I had not missed him. Reloaded, intending to follow him ; but, coming up to the rocky, bushy ground he was on, found him dead, being shot through the heart, and ordered the Highlander, who was with me, to take him home, after I had thoroughly examined him.

The roebuck (continues the Colonel) is the most timid and innocent of all animals, and about the size of a common two-years-old fallow-deer. It differs from them a little in colour and also in shape, but more particularly in the character and colour of the head and muzzle ; the former is very small, and the latter is barred with white. They are always lean, and the only fat found upon them is a small piece on the end of the rump.”

The roebuck is still to be found in various parts of the Highlands of Scotland, from Ross-shire to the lower end of Loch Lomond, particularly in the neighbourhood of this lake on the property of the Duke of Montrose, and that of Sir James Colquhoun ; but they are more plentiful in some of the islands on the western coast of Scotland. Of late years, they have increased, but there are not any

in the remote Highlands ; for instance, in Sutherlandshire or Caithness.

**ROE-BUCK HUNTING.** I was uncommonly well mounted on an English mare, whose dam was said to have been by a very fine horse, which I discovered was a son of King Herod : but she was rather too warm in her temper, which does not answer amongst trees. The hounds consisted of only two couple, and those very indifferent ones. I lamented that mine were not with me, but they were gone to Monsieur de Beaumont's.

After trying for a considerable time, we at length found ; and the hounds having a good scent, ran tolerably for near two hours, during which time I only got one view of the game : however, he soon began to run shorter in rings and lay down ; and, as the sun got up, the dew went off, and the scent, of course, became weaker. I then dismounted, and took my stand under an oak, intending to have shot at the roe-buck with the air gun which had succeeded so well with the wild boar ; but, before I could pull the trigger, he was in thick covert.

After a few rings and cold hunting, he came within twenty yards, when I discharged my piece, and was convinced, both by the springing and by the sound of the ball, that I had hit him. I gave several view-halloos, but the company either could not hear, or did not understand me ; though had I shot with powder, they must have been apprised by the report.

In about twenty minutes a hound came on the scent, but gave tongue faintly. I caught him by the ear, and he spoke most feelingly : this brought up the others, and with them the huntsman, whom I told of what had happened. He could not, at first, believe that I had wounded the roe-buck ; but I assured him of the fact, and desired him to let me go to the next avenue, and there lay on the hounds. He did so, and the dogs evidently enjoyed the scent better. This I thought a favourable omen, as it probably resulted from

the dropping of the blood on the cover. They were bringing the game across the avenue, directly to me, where I should have another shot ; but I imagine that he had either seen or winded me, as the scent turned to the right, about two hundred yards off. I saw him cross, however, and his shoulder appeared broke, as he could scarcely get over a gutter.

After I had hallooed, and the huntsmen had sounded their horns, the hounds began to run very briskly, and at last there was a dead silence. I concluded the buck was killed ; but in this I was mistaken, for he was at bay, and sometimes attempted to scramble off ; but, perceiving he could not go far, I rode before him, and sent a ball between his eyes.

The rest of the company soon came up, and were highly delighted ; but the keepers could not comprehend the nature of an air-gun, though they carefully examined the piece, and the effect of the ball. It must, however, in this instance, have shot very weak, or the first shot must have gone through the deer's head ; but it had broken the shoulder, and, being turned by a bone, had come out through the skin of the neck. This was deemed very extraordinary ; but I once shot a deer with the same gun, at Thornville Royal, which was in the act of leaping a fence : the ball went in at the shoulder, exactly opposite the heart, but it turned, went along the upper part of the belly, between the skin and the intestines, and came out at the hock.

The day was now intensely hot, and the flies, which surrounded us in myriads, would soon have saved the cook the trouble of roasting the game, had it not been carried home. However, being properly placed on a tray slung for the purpose, and covered with branches, it was conveyed to the castle with great parade, the horns playing all the way.—*Thornton's Tour in France.*

**ROOK.** The rook is about the size of the carrion crow, but its plumage is more glossy. It also differs in having its nostrils, and the root of the bill, naked ; in the crow these are covered with bristly hair. This arises from the rook's thrusting its bill continually into the earth in search of worms and other food.

Besides insects, the rooks feed on different kinds of grain, thus causing some inconvenience to the farmer ; but this seems greatly

repaid by the good they do to him, in extirpating maggots of some of the most destructive of the beetle tribe.—In Suffolk, and in some parts of Norfolk, the farmers find it to their interest to encourage the breed of rooks, as the only means of freeing their grounds from the grub which produces the cock-chaffer, which in this state destroys the roots of corn and grass to such a degree, “ that (says Mr. Stillingfleet, one of the most accurate observers of nature whom this country has ever produced) I have myself seen a piece of pasture land where you might turn up the turf with your foot.” An intelligent farmer in Berkshire informed this gentleman, that one year, while his men were hoeing a field of turnips, a great number of rooks alighted in a part of it where they were not at work. The consequence was a remarkably fine crop in this part, while in the remainder of the field there was scarcely any turnips that year.

These birds are gregarious, being sometimes seen in flocks so great as to darken the air in their flight. They build their nests on high trees, close to each other; generally selecting a large clump of the tallest trees for this purpose. When once settled, they every year frequent the same place. Rooks are, however, but bad neighbours to each other; for they are continually fighting and pulling to pieces each other’s nests. These proceedings seem unfavourable to their living in such close community; and yet, if a pair offers to build on a separate tree, the nest is plundered and demolished at once. Some unhappy couples are not permitted to finish any nest till the rest have all completed their buildings; for as soon as they get a few sticks together, a party comes and demolishes the whole. It generally happens that one of the pair is stationed to keep guard, while the other goes abroad for materials. — From their conduct in these circumstances our cant-word *rooking*, for cheating, originated.

As soon as the rooks have finished their nests, and before they lay, the cocks begin to feed the hens; who receive their bounty with a fondling tremulous voice, and fluttering wings, and all the little blandishments that are expressed by the young while in a helpless state. This gallant deportment of the males is continued through the whole season of incubation.

New-comers are often severely beaten by the old inhabitants (who are not fond of intrusions from other societies), and even frequently driven quite away. Of this an instance occurred near Newcastle, in the year 1783. A pair of rooks, after an unsuccessful attempt to establish themselves in a rookery at no great distance from the Exchange, were compelled to abandon the attempt, and take refuge on the spire of that building; and, although continually interrupted by other rooks, they built their nest on the top of the vane, and reared their young, undisturbed by the noise of the populace below them:—the nest and its inhabitants were of course turned about by every change of wind. They returned and built their nest every year on the same place, till the year 1793, soon after which the spire was taken down. A small copperplate was engraved, of the size of a watch-paper, with a representation of the top of the spire and nest; and so much pleased were the inhabitants and other persons with it, that as

many copies were sold as produced to the engraver the sum of ten pounds.

A remarkable circumstance respecting these birds occurred a few years ago at Dallam Tower, in Westmoreland, the seat of Daniel Wilson, Esq.—There were two groves adjoining to the park; one of which had for many years been the resort of a number of herons, that regularly every year built and bred there. In the other was a very large rookery. For a long time the two tribes lived peaceably together. At length, in the spring of 1775, the trees of the heronry were cut down, and the young brood perished by the fall of the timber. The parent birds, not willing to be driven from the place, endeavoured to effect a settlement in the rookery. The rooks made an obstinate resistance; but, after a desperate contest, in the course of which many of the rooks and some of the herons lost their lives, the latter at length succeeded in obtaining possession of some of the trees, and that very spring built their nests afresh. The next season a similar conflict took place; which, like the former, was terminated by the victory of the herons. Since this time, peace seems to have been agreed upon between them: the rooks have relinquished part of the grove to the herons, to which part alone they confine themselves; and the two communities appear to live together in as much harmony as before the dispute.

The following anecdote of this sagacious community is related by Dr. Percivall, in his *Dissertations*:—"A large colony of rooks had subsisted many years in a grove on the banks of the river Irwell, near Manchester. One serene evening, I placed myself within the view of it, and marked with attention the various labours, pastimes, and evolutions, of this crowded society. The idle members amused themselves with chasing each other through endless mazes; and, in their flight, they made the air resound with an infinitude of discordant noises. In the midst of these playful exertions, it unfortunately happened that one rook, by a sudden turn, struck his beak against the wing of another. The sufferer instantly fell into the river. A general cry of distress ensued. The birds hovered, with every expression of anxiety, over their distressed companion. Animated by their sympathy, and, perhaps, by the language of counsel known to themselves, he sprang into the air, and, by one strong effort, reached the point of a rock which projected into the water. The joy became loud and universal; but, alas! it was soon changed into notes of lamentation; for the poor wounded bird, in attempting to fly towards his nest, dropped into the river, and was drowned, amidst the moans of his whole fraternity."

There seems to exist a wonderful antipathy between these birds and the raven: Mr. Markwick says, that in the year 1778, as soon as a raven had built her nest in a tree adjoining to a very numerous rookery, all the rooks immediately forsook the spot, and have not returned to build there since. At the Bishop of Chichester's rookery, at Broomham, near Hastings, upon a raven's building her nest in one of the trees, all the rooks forsook the spot; they, however returned to their haunts in the autumn, and built their nests there the suc-

ceeding year. It is no very difficult task to account for this antipathy. The raven will scarcely suffer any bird whatever to come within a quarter of a mile of its nest, being very fierce in defending it. It besides takes the young rooks from their nests, to feed its own young. This Mr. Lambert was an eye-witness to, at Mr. Seymer's, at Harford, in Dorsetshire; for there was no peace in the rookery, night nor day, till one of the old ravens was killed, and the rest were destroyed.

They begin to build in March; and, after the breeding season is over, forsake their nesting trees, and for some time roost elsewhere; but they have always been observed to return in August. In October, they repair their nests.

When the first brood of rooks are sufficiently fledged, they all leave their nest-trees in the day time, and resort to some distant place in search of food; but return regularly every evening, in vast flights, to their nest-trees; where, after flying round several times with much noise and clamour till they are all assembled together, they take up their abode for the night.

Mr. White, in his *Natural History of Selborne*, speaking of the evening exercises of rooks in the autumn, remarks, that just before dusk, they return in long strings from the foraging of the day, and rendezvous by thousands over Selborne Down, where they wheel round, and dive in a playful manner in the air, exerting their voices; which being softened by the distance, become a pleasing murmur, not unlike the cry of a pack of hounds in deep-echoing woods. When this ceremony is over, with the last gleam of light, they retire to the deep beech woods of Tisted and Kepley. We remember (says Mr. White) a little girl, who as she was going to bed used to remark, on such an occurrence, in the true spirit of physico-theology, that the rooks were saying their prayers; and yet this child was much too young to be aware that the scriptures have said of the Deity—that “he feedeth the ravens who call upon him.”

In the parts of Hampshire adjacent to the New Forest, after the rook has reared his progeny, and has carried off such of them as have escaped the arts of men and boys, he retires every evening at a late hour, during the autumn and winter months, to the closest coverts of the forest, having spent the day in the open fields and inclosures in quest of food. His late retreat to the forest is characteristic of the near approach of night.

Retiring from the downs, where all day long  
They pick their scanty fare, a black'ning train  
Of loitering rooks thick urge their weary flight,  
And seek the shelter of the grove.—

But, although the forest may be called his winter habitation, he generally every day visits his nursery; preserving the idea of a family, which he begins to make provision for very early in the spring.

Among all the sounds of animal nature, few are more pleasing than the cawing of rooks. The rook has but two or three notes,

and when he attempts a *solo* we cannot praise his song; but when he performs in *concert*, which is his chief delight, these notes, although rough in themselves, being intermixed with those of the multitude, have, as it were, all their rough edges worn off, and become harmonious, especially when softened in the air, where the bird chiefly performs. We have this music in perfection when the whole colony is raised by the discharge of a gun.

Dr. Darwin has remarked, that a consciousness of danger from mankind is much more apparent in rooks than in most other birds. Any one who has in the least attended to them, will see that they evidently distinguish that the danger is greater when a man is armed with a gun than when he has no weapon in his hands. In the spring of the year, if a person happens to walk under a rookery with a gun in his hand, the inhabitants of the trees rise on their wings, and scream to the unfledged young to shrink into their nests from the sight of the enemy. The country people, observing this circumstance so uniformly to occur, assert that rooks can smell gunpowder.

In England these birds remain during the whole year; but both in France and Silesia they migrate. It is a singular circumstance that the island of Jersey should be entirely without rooks; particularly when we know that they frequently fly over from our country into France.

The young birds, when skinned and made into pies, are much esteemed by some persons.

ROOK SHOOTING. See SHOOTING.

ROUSE. A term in stag hunting: when an out-lying deer is found by the hounds in cover, he is said to be *roused*. When a deer is carted and carried to any particular spot for sport, and there liberated, he is then said to be *turned out*.

ROWEL. The small circular star, with sharp points, moving upon a pivot at the heel of the spur, is so called.

ROWEL IN A HORSE. "Rowels for horses (says Mr. Clark of Edinburgh) answer the same purpose as issues in the human body. The method of introducing them is by making an incision through the skin, about three-eighths of an inch long, and then separating the skin from the flesh with the finger, or with a blunt horn, all round the orifice, as far as the finger will easily reach, then introducing a piece of leather, very thin, shaped round, about the size of a crown-piece, having a large round hole in the middle of it. Previous to introducing the leather, it should be covered with lint or tow, and dipped in some digestive ointment; a pledget of tow, dipped in the same ointment, should likewise be put in the orifice, in order to keep out the external air. The parts around it soon swell, and this is followed with a plentiful discharge, from the orifice,

of yellowish serum or lymph; and in two or three days at most, there discharges a thick gross white matter: the rowel is then said to suppurate.

These artificial vents act by revulsion or derivation; and hence they become of great use in many cases, as they empty the surrounding vessels by a regular slow discharge of their contents, and are even of great service when there is a redundancy or fullness of humours in general, which may require a gradual discharge, in preference to greater evacuations by purging medicines, &c. Rowels should be placed (especially in some particular cases) as near the affected part as possible; and, at all times, they ought to have a depending orifice, in order to admit of a free discharge of the matter that may be contained in them.

The parts in which they may be most conveniently inserted, and where they are found to answer the purpose best, are the belly, inside of the thighs, the breast, and outside of the shoulders and hips. They are sometimes, but very injudiciously, put in between the jaw-bones under the root of the tongue, where they never come to a proper suppuration, on account of the constant motion of the parts in eating, &c. neither do they answer any good purpose

from being placed in that situation. In some disorders it is found necessary to put in several of them at once, in order to make a sudden determination from the parts affected; but this should be regulated by the horse's age and strength, and by the circumstances that require their use."

Mr. Clark here adverts to the possibility of their misapplication.—“But (says he) though rowels are found very beneficial in some cases, yet, like a number of other operations common to horses, they frequently, instead of suppurating, become gangrenous. Hence, the cure proves worse than the disease they were intended to remove. Thus, in violent fevers, where they are frequently very injudiciously applied, they never suppurate properly. Whether this proceeds from the quickness of the pulse, together with the violent rapidity with which the fluids in general are then carried through the vessels, or from the violent agitation in which the whole system is thrown, it is difficult to determine; but experience confirms the fact. In such cases, the surrounding parts, where the rowel is placed, seldom or never swell (as in the ordinary course, when they suppurate properly), but appear dry, or much in the same state as when they were first put in; there is little or no discharge from the orifice, and the little that does come is thin, ichorous, and bloody. In such cases, they ought to be taken out immediately, and the parts well fomented with a strong infusion of chamomile, or an emollient poultice applied, if it can be properly fixed, and frequently repeated. At intervals, the parts ought likewise to be bathed with ardent spirits, as that of wine, turpentine, &c. covering the parts from the external air; and, provided there be no fever at the time, two or three ounces of Peruvian bark may be given through the day, either

made into balls, or given in a liquid; and this course should be continued till the threatening symptoms are removed."

Gibson gives an instance of cancer being produced by a rowel placed near the glandular parts in a horse, and which proved fatal to the animal.

The practice of rowelling, however, Mr. Clark considers of great use “in carrying off rheums, or defluxions from the eyes; in extensive swellings of the glands, &c. about the throat and jaws, which threaten a suffocation; or when the head seems particularly affected, as in the vertigo or staggers, apoplexy, &c. in recent lameness; swellings of the legs and heels, attended with a discharge of thin ichorous matter, &c. in large and sudden swellings in any part of the body; or when extravasations of the fluids have taken place, from blows, bruises, &c. or when a horse has had a severe fall, &c. and in a variety of other cases,” which he apprehends will occur to the judicious practitioner, without the necessity of further injunctions on the subject.

If we may be allowed to differ from so experienced a practitioner, we would venture to call in question the propriety of bathing, with stimulating liquids, the parts which swell without suppurating. To say nothing of its being inconsistent with the emollient treatment by fomentation and poultices, we apprehend the want of a kindly discharge to arise, in such cases, from the degree of inflammation in the part having advanced beyond the suppurative point. Else why the benefit which almost invariably results from withdrawing the rowel, and employing the common means of abating inflammation? We submit, therefore, to the veterinary fraternity, whether, at least, the application of spirit of turpentine, which is extremely pungent, to the skin of a horse, should not rather be dispensed with?

**RUD** or **FINSCALE** is not a common fish; it is found in the Cherwell, near Oxford, and in Northamptonshire, in Lincolnshire, in some of the lakes in Yorkshire, and in the Trent, where it is believed to breed in the Fleets, which are large pieces of standing water, supposed to have been the ancient course of that river, from whence they escape in high floods into the Trent; they affect ponds and still waters, where they breed and grow uncommonly quick, but rarely exceed two pounds weight. They are doubtless a distinct species, notwithstanding Mr. Walton mentions them as being produced by the junction of the bream and roach.

The body of the rud is broader than the carp, more like that of the bream, but much thicker; the head is small, the palate and teeth

like the carp; on the covers of the gills are spots of a blood colour; the irides are yellow, varying in some almost to redness; the nostrils large, and by some said to be double on each side; the back is arched, sloping off suddenly at the two extremities; the scales are very large, like the carp; the side line is slightly incurvated: the back is of an olive, the sides and belly are of a gold colour, with certain red marks; the ventral, anal fins, and the tail, (which is forked,) are generally of a deep red, and the dorsal fin is darker than the rest; the usual length of this fish is from ten to sixteen inches. It lives on insects and grass, and is preyed upon by the voracious fish, and the anseres. In rivers, the rud's haunts are in deepish gentle streams and deep still water, where the bottom is a kind of slimy mud sand, or fine gravel, and also among weeds: in pools, chiefly in holes among the weeds. They are always in season, except at the time of spawning, which is in April, when the male fish have small white spots about their heads, and the scales of both sexes feel more rough; they swim in shoals, casting their spawn upon and among the aquatic plants, to the number, according to the Elements of Natural History, of 91,000 ova. Their flesh is exceedingly wholesome, and holds a distinguished rank for its fine flavour; but they are very scarce.

Mr. Pennant believes the Shallow of the Cam, which grows to the length of thirteen inches, and spawns in April, to be no other fish than the rud.

The angler will find the rud worth his attention; the tackle must be strong, but fine, with a quill float, and a hook proportioned to the bait; the same ground-bait is to be used as for carp and chub, fishing about the same depths as for the latter, except on the ground, for they feed naturally near the surface; they will in this way take red-worms, gentles, wasp-maggots, cadis, and red paste. Some use ground-bait of boiled malt, and prefer a small red-worm to any other bait. In fishing among weeds, have neither float nor shot, and let the worm, or other bait, sink a little under water: at the top they are taken either with natural or artificial flies, by whipping with a long, and dibbling or bobbing with a short, line. In warm, bright weather, the rud will bite early and late; when coolish, the fore and afternoons; and in winter, the middle of the day; when hooked, this fish struggles hard, and requires time in landing, and is so tenacious of life, as to retain it after being taken out of the water a considerable time.

RUFF or POPE is found in several of our streams; the river Yare, in Norfolk, affords perhaps the greatest plenty: it is a gregarious fish, assembling in large shoals, and keeping in the deepest part of the water; it somewhat resembles a perch, though the form is more slender, and the length rarely exceeds six inches, the teeth are very small and disposed in rows, it is marked on the jaws with a double course of half circles; the upper part of the eye is of a dark brown, the lower part somewhat yellow, and the globe of it black; the first rays of the dorsal fin (which is spotted with black) are like those of the perch, strong, sharp, and spiny, the others soft; the

body is covered with compact scales, the back and sides are of a dirty green, the last as well as the belly inclining to yellow, but both spotted with and the tail marked with transverse bars of black; their principal spawning time is the beginning of April, but some are said to spawn again in October, and, in the Elements of Natural History, are said to deposit 75,000 ova.

To the young angler, the ruff yields good sport: they associate in great numbers, their haunts are in recluse places, where the water is deep, and runs quietly with a loamy or muddy bottom, and also in still water; the tackle should be fine, the hook No. 7, and a quill float, the bait (a small well-scoured red-worm) must just run on the ground, and either throw in some clay balls with worms, as directed in perch fishing, or if the water be clear, use common mud balls to colour it; three rods may be easily managed, the baits touching the bottom; when there is a bite, strike directly, for they gorge so hastily, that the disgorging or a knife must frequently be used, to get out the hook; by thus angling for them, six or eight dozen are often caught at a standing. Either in spring or summer, with a brisk, warm wind, they will bite all day; and will sometimes in cold weather take the bait very freely. The ruff, for the delicacy and richness of its flavour, as well as for its being considered very nourishing, is more admired than the perch. They are to be dressed in the same manner.

**RUFF AND REEVE.** The ruff is about a foot in length, with a bill of about an inch. The face is covered with yellow pimples; and the back part of the head and neck are furnished with long feathers, standing out somewhat like the ruff worn by our ancestors; a few of these feathers stand up over each eye, and appear not unlike ears. The colours of the ruffs are in no two birds alike: in general, they are brownish, and barred with black; though some have been seen that were altogether white. The lower parts of the belly and the tail coverts are white. The tail is tolerably long, having the four middle feathers barred with black; the others are pale brown. The legs are of a dull yellow, and the claws black.—The female, which is called the reeve, is smaller than the male, of a brown colour, and destitute of the ruff on the neck.

The male bird does not acquire his ruff till the second season, being till that time in this respect like a female: as he is also from the end of June till the pairing season, when nature clothes him with the ruff, and the red pimples break out on his face; but after the time of incubation the long feathers fall off, and the carbuncles shrink in under the skin so as not to be discerned.

These are birds of passage; and arrive in the fens of Lincolnshire, in the Isle of Ely, and the East Riding of Yorkshire, in the spring, in great numbers. Mr. Pennant tells us, that in the course of a single morning there have been above six dozen caught in one net: and that a fowler has been known to catch between forty and fifty dozen in a season.

The males are much more numerous than the females, and they have many severe contentions for their mates. The male chooses a stand on some dry bank, near a splash of water, round which he runs

so often as to make a bare circular path : the moment a female comes in sight, all the males within a certain distance commence a general battle ; placing their bills to the ground, spreading their ruff, and using the same action as a cock : and this opportunity is seized by the fowlers, who, in the confusion, catch them, by means of nets, in great numbers.

An erroneous opinion prevails very generally, that the ruffs, when in confinement, must be fed in the dark, lest the admission of light should set them to fighting. The fact is, that every bird, even when kept in a room, takes its stand as it would in the open air ; and if another invades its circle, a battle ensues. A whole room full of them may be set into fierce contest by compelling them to shift their stations ; but, after the disturber has quitted the place, they have been observed to resume their circles, and become again pacific. In confinement, their quarrels originate in the circumstance of the pan containing their food not being sufficiently large to admit the whole party to feed without touching each other. When the food has been divided into several pans, the birds have continued perfectly quiet.

The reeves lay four eggs, in a tuft of grass, about the beginning of May ; and the young are hatched in about a month.

It is not known with certainty in what country these birds pass the winter.

**RUNNING HORSES.** See **RACE HORSE.**

**RUNNING THRUSH, OR FRUSH.** See **THRUSH.**

**RUPTURE.** Gibson describes this complaint in horses in the following way : “ When any part of the guts or caul (says he) makes its way through the muscles of the lower belly, it is called a rupture ; when any part of the guts falls into the scrotum, it is said to be a complete rupture ; when at the navel, it is called an umbilical rupture. I once saw a fine Spanish stallion with a complete rupture ; the swelling was so extremely large, that the gut extended the scrotum down to his hock. This circumstance rendered the cure in a great measure impracticable. It was the only one of the kind I ever saw, and, in fact, it is a case that must seldom happen, the position of a horse’s body being such, as cannot so easily expose him to ruptures into the scrotum, as men are, whose posture is erect. I also have seen a gelding, where probably some part of the gut or peritoneum had made its way through the vaginal passage, into the membraneous parts of the sheath on the right side ; for the omentum, or caul, seldom reaches so low in a horse, his continual horizontal motion throwing it, for the most part, forward in wrinkles. The swelling was about the size of a goose’s

egg, a great part of which might be thrust back with the finger into the cavity of the lower belly, but immediately returned in the manner of a flatulent tumour ; and perhaps there might be some portion of air along with it. The cure was never attempted, because it was little or no hindrance to the horse in his business, the swelling being generally fuller when he stood still than when he worked.

But the most usual ruptures are more upwards, and proceed from strains in working, or from being staked, or gored by bullocks, violent kicks from other horses, very high leaps over gates and hedges ; all which things sometimes divide the muscles of the lower belly, and oftentimes without piercing or rending the skin, whereby a portion of the intestines, with a part of the peritoneum, and when the wound happens to be forward, part of the caul may also be lodged where these muscles are separated or divided, and so cause a swelling of a proportion and size equal to the rent made in the part. An instance of this kind I once saw, of a very fine Flanders mare, that had a rupture near her navel of a considerable size, which, however, did not prevent her working, but as it grew larger it became troublesome ; and a very eminent and able surgeon, imagining the substance to be fleshy, and of the nature of a wen,

persuaded me to have some trial made of it by excision, for it felt solid as she stood on her legs, which might be owing to part of the caul (which is always rolled forwards in working horses), and along with this, an adventitious growth of flesh, caused by the rending of the muscles and membranes, for when she was thrown upon her back, part of the substance went inwards, and plainly discovered her malady to be a rupture.

I have known some few instances of umbilical ruptures, that have been caused by rowels in the belly, when they have been cut too deep, and perhaps were afterwards neglected. And I knew a horse with a rupture of this kind, perform a journey of several hundred miles, without any great inconvenience, only, that he always went sluggish at his first setting out, but more cheerfully as he emptied himself. Nevertheless, this is a very great defect, and few horses with such infirmities can be long useful. I have seen other ruptures, and these are, indeed, the most usual, that push out on the sides of the lower belly, where the tunica vaginalis passes through the rings of the muscles, with the spermatic vessels, into the scrotum; and in geldings they seldom reach further than the first ring, which is a little way above the groin; but when they happen on the sides of the flanks, they are then, for the most part, owing to such accidents as have been above mentioned. They generally bunch out about the size of a man's fist, and are fullest when the horse stands still in the stable, especially after feeding and watering, and in broken-winded horses they rise and fall with the agitation of the flanks; they are soft, and yield to the pressure of the hand, and in most of them one may feel the vacuity through which the viscera make their way immediately to the skin. But, as there is no absolute cure to be expected in such cases, the safest way is to feed moderately, and in small quantities, with small draughts of water, and to use such horses gently. In all beginning ruptures, a fomentation made of oak bark, boiled in equal parts of the sharpest vinegar, and smith's forge water, have been used by farriers for a general application; for, in horses, bandage and trusses of any kind are, for the most part, impracticable."

This experienced writer concludes his subject with an instance of a very fine gelding, that was killed by a rupture, and in a manner somewhat extraordinary.—  
"This horse (says he) belonged to a per-

son of distinction, and was abroad with our army in Germany and the Netherlands. He received a hurt while he stood at the piquet along with some other horses; yet went through his business very well for the space of two years, notwithstanding that accident; but, after a hard day's hunting, was taken with the gripes, of which he died. I was sent for to examine his abdomen, where there was something that surprised all that saw him opened. The ring through which the tunica vaginalis passes, appears plainly in a horse to be formed of the tendinous part of the muscles, has the strength and firmness of a ligament, and resembles a hem or large oilet-hole, such as we see in the sails of a ship. One half of this ring was torn off from the flesh, and lay across the orifice, which tied up a duplicature of the colon so tight, that nothing could pass through it; and this was evidently the cause of his sudden death.

I have briefly related this case (adds he) in order that those who are employed about horses, may be so far informed in such things, as to examine them carefully when the gripes, or any other sudden disorder, seizes them. For if the duplicature of the gut had been forced back into the cavity of the lower belly, when he was first seized, his death might probably have been prevented; for this rupture seldom appeared larger than a man's fist."

**RUSSIAN POINTER.** A few years back, a rough-coated dog, of the water spaniel breed, was introduced to the notice of the sportsmen of this country, under the denomination of the *Russian pointer*. Whether he be originally Russian, is very doubtful; but he is evidently the ugliest strain of the water spaniel species; and, like all dogs of this kind, is remarkable for penetrating thickets and bramble bushes, runs very awkwardly, his nose close to the ground (if not muzzle-pegged) and frequently springs his game. He may be taught to *set*, and so may a terrier, or any dog that will run and hunt, and even pigs, if we are to believe the story of Sir Henry Mildmay's black sow; but to compare what is called the Russian pointer with the pointer, properly so called, or the setter, would be outrageous; nevertheless, we are not prepared to say, that out of a hundred of these animals, one, tolerable, could not be found: but we should think it madness to recommend the Russian pointer to sportsmen, *unless for the purpose of pursuing the coot or the water-hen.*

Chance, in all probability, first introduced the Russian pointer to the notice of some fanciful sportsmen : to see a dog of this description set steadily, would appear strange ; and, from this very circumstance, the animal might obtain credit for other qualities which he did not possess. However, the use of the Russian pointer was very limited, and attended, for the most part, with unqualified dissatisfaction.

RUT. Deer, both red and fallow, are said to go to rut at the season of copulation.

RUTTING TIME. The rutting season commences the latter end of August, and continues to the first and second week in October ; during which, both the stag and the buck assume a degree of courage, in approaching man, that they never display at any other period of the year. At this season, their necks swell ; they range from one place to another incessantly, in seeming search of some object to attack ; the voice of the stag is loud and alarming to those who have not been accustomed

to hear it. When opposed, they are so exceedingly strong and ferocious, that no common force can stand against them : they attack an individual in rutting time, with a certainty of success. Some years ago, the lock-smith, who inspected the gate locks of Windsor Great Park, weekly, was pursued by a stag, and, when within a few yards of him, most luckily escaped by climbing a small tree, where he was kept in jeopardy nearly twenty-four hours, till the next day the stag retreated upon the accidental approach of some of the keepers. Also, about the same period, a girl, fourteen years of age, passing through Hackwood Park, near Basingstoke, in Hampshire (and having on a red cloak) was attacked by one of the oldest stags in the park, who literally perforated her body in almost every part, and extended his fury to her apparel :—the melancholy spot was covered with rags, and the body of the unfortunate girl was so maimed and disfigured, that it scarcely retained the appearance of a human body.

## S

SACCADE. In the manege, a jerk, more or less violent, given by the horseman to the horse, in pulling or twitching the reins of the bridle, all on a sudden, and with one pull ; to correct a horse that lies heavy upon the hand, or obstinately arms himself. This is used to make the horse carry well : though it ought to be used discreetly, and but seldom.

SADDLE. The saddles now in use, when they first came up, were distinguished by the name of hunting saddles, and the old fashioned ones, with one deep skirt, were called road saddles. The inconveniences of these saddles have put them out of use, so that you rarely see one now, but with old post harness. Those who have never rode on these saddles, may not be aware of their inconveniences, and those who are fond of singularity may be induced to order one on the old construction. The absurdest whims are followed, if set on foot by those who lead fashions ; witness, a short time since, every horse must have a collar and martingal, let his head be placed by nature in the most desirable manner. At another time, every horse must have a breast-plate, though his belly was like a mare with foal ; others with cruppers, though the horse was tucked up, and run through his girths.

Now the inconveniences of the old single-flap saddles are, that if the flap is short, your knee is not protected from the girths and straps ; if the flap is made deeper, it unpleasantly interferes with the top of the boot ; if you have the flap still longer, the stirrup-leather will cause it to rub and chafe the leg. If you have a surcingle to prevent it, the stirrup leather is confined and unpleasant ; and, should your foot quit the stirrup, you cannot, without stopping your horse, conveniently get your stirrup again. These inconveniences have done away their use for the present.

The modern saddle does away all these inconveniences, by the stirrup-leather being outside the deep flap ; and though the flap be cut ever so deep, it needs no surcingle to keep down, provided the leather is of that substance it ought to be ; but if it is a thin flabby piece of leather, it will rise with your knees, and be unsafe to ride a horse over leaps, &c. The short flap covers the aperture where the stirrup leather comes through, and when properly made, you feel no inconvenience from it ; but I have rode on saddles where the edges of this flap have chafed me—I believe it might be occasioned by the flaps being too short.

I have seen a single flap-saddle, with a

small neat hole cut for the stirrup leather, to come on the outside. I see no other objection to this than the eye-sore, which would be thought nothing of, if general, and the preclusion of altering your stirrup without dismounting. Now, gentlemen have done away this convenience in the modern saddle, by having the ends of the stirrup leather put under the deep flap, and when there is occasion to have them altered, it is attended with some difficulty, and the flaps are liable to be, and are frequently torn when they become hard and dry with doing it. But I prefer the end of the stirrup leather on the outside, that I may alter my stirrup as I like, in a full gallop if I please.

It is certain, were any thing constructed and brought to the highest perfection, the most ridiculous absurdities would be substituted for fashion's sake. But a few years ago, the pommel of the saddle was made to a point, as small as the end of my finger, which might mortally injure a person were he to have the misfortune to be thrown upon it. If a regimental saddle had a high cantle, to prevent the forage and necessaries a soldier carries on his march, riding on the saddle, what necessity can there be for the gentleman to adopt the same, who will not carry his great coat behind him.

Let us consider the use and utility of the saddle, and we find it intended to enable the horse to carry his burthen with ease and comfort to himself; this is the first consideration—and the next is, to make the seat pleasant, secure, and comfortable to the rider; other considerations are convenience and fashion.

But in what manner does the saddle relieve the horse?

First, he is relieved from the friction of the thighs. The action of the horse always gives the body motion, and the saddle prevents the horse receiving the friction he would endure if bare-backed, or only a cloth on.

Next, the weight of the rider is distributed and conveyed to parts more capable of sustaining the weight. For instance, when you ride without a saddle, the horse sustains your weight in the middle, or most weak part of the back; but when you ride on a saddle, your weight is distributed, for the saddle has bearings before and behind, but none in the centre, or weak part of the back.

From hence we may infer, that the saddle should be proportioned to the size

of the horse; and the short saddles used for racing, are constructed more for lightness than ease. Not that I would have a saddle too long, as to reach from his withers to his rump; but that the bearings before are clear of any interference with the shoulder or plate-bone, and behind not to extend to the hips by four inches.

The fitting of the saddle greatly contributes to the ease of the horse, and this commonly is only partially considered; for when a strange saddle is put on a horse, if it is not likely to crush his withers before, and come down on the back-bone behind, it is judged sufficient. But if a horse has a weight to carry, or a long journey to perform, particular attention should be paid to the fitting of the saddle, for a horse may be rendered very uncomfortable, though the saddle neither presses on his withers or his chine.

For the saddle to fit well, the bearing should be equal on every part that is intended it should touch; and the closer it comes down, so that neither the weight of the rider, nor settling of the pannel, can bring it to injure the withers or chine, the better.

Examine, therefore, with your finger from the bearing of the side of the withers, to the point of the tree, if it appears to have equal pressure; and the same all round the hinder part of the saddle. If there is space for your finger between the pommel and the withers, and likewise between the chine bone and back part of the saddle, you may reasonably suppose it will not come down to injure the horse, unless the tree is weak, and spreads with the weight of the rider, or the pannel is newly stuffed.

On the other hand, if you perceive the points so narrow, that the saddle cannot come to its bearings till the girths or weight of the rider brings it down, the extra pressure at these points for a considerable time or distance, must occasion heat and inflammation. The same remark will stand good for the hind part of the saddle.

Again, should the saddle come down on its bearings, and the points stand so wide as not to touch, and the pommel stands high so as not to injure the withers, it is said this saddle will not hurt him. Agreed—it will not, to ride a small distance, or to exercise, or to give a horse a lesson, for on this principle the saddles for general use are made, to suit all horses;

the points of the tree are short, and sufficiently wide, the pommel cut high, so that a bearing is sure to take place, without crushing the withers. But these cannot be called saddles to fit. And when long journeys are taken in hot weather, with saddles that have such contracted bearing, expect to find inflammation and warbles.

A lady's saddle requires the most particular exactness in fitting, or the horse will be cruelly galled by it; this makes people attend much to it, though many err in their conception of the saddle fitting. A lady's saddle should be very deep in the points, and should sit close from the top of the bearing to the extreme ends of the points. The manner a lady rides will ever give the saddle a preponderance to the near side, at which time the saddle is sustained by the point on the near side, and the bearing on the off, which may be compared to a hook; the depth and closeness of the near point, preventing the bearing on the off side unhooking itself. The closer the pommel comes down to the withers, so as neither weight nor settlement can make it touch, the better; and a trifling easement may be given on the off side of the pommel, but not to extend to any part where the bearing should be, lest you loosen that bite or hold, which sustains the saddle.

If the tree does not fit in the manner described, you cannot stuff the pannel to insure its not injuring the horse; and where the tree fits, all superfluous stuffing in the pannel, under the idea of rendering it soft and pleasant to the horse, must be avoided, as the elasticity of the stuffing permits the saddle to get out of place. Thick-stuffed pannels are not always easy for the horse in gentlemen's saddles, for it is difficult to be certain of so much stuffing being regular; and those parts that happen to be the thickest, when they settle and become hard with the sweat, must be uneasy, and occasion warbles.

Respecting saddles keeping their place on the horse's back, there are two contrivances:—the crupper, to prevent it getting too forward; and the breast-plate, to prevent it getting back: but neither are wanted by gentlemen for road-riding, who keep their horses in condition, and have their saddles fitted to them. For hunting, some horses require a breast-plate; deep-chested horses climbing hills, their bodies tucked up by running, their saddles will get back, and require a breast-

plate, which should be of worsted for its elasticity.

The crupper is useful: in breaking we use it, because every horse should be accustomed to it, and because the saddles we use are not fitted to the horses we ride. Many horses when full of flesh and out of condition, cannot keep a saddle in its place without a crupper. But dry wholesome food, and sufficient exercise, with good grooming, soon alter the shape and condition, that a horse can carry the saddle without the crupper.

Ladies' saddles, when properly fitted, will not require cruppers more than gentlemen's, but the girths crossed from the hind part of the saddle to the front, will keep them more steady; or a strap from the hind part of the saddle to the fore girth on the off side, may prevent the saddle twisting to the near side, as it usually does.

Having considered what relates to the ease and comfort of the horse, the rider's accommodation comes next to be considered; for a saddle may fit a horse, yet be a most awkward, unpleasant seat for the horseman. Those who have rode on a variety of saddles, both of the old and modern make, are sensible of this. The modern saddles of our best makers, are hardly to be improved upon; I don't mean to attempt it, but shall leave it to the saddlers, whose more particular province it is, declaring I cannot suggest any ideas to assist them therein.

But, for the information of gentlemen, I shall develop the seat of a saddle, which will shew that the comfort, ease, and security of riding, depend much on the ingenuity and skill of the saddler. The upper part or seat of the saddle, is formed or shaped by the straining of what is called web. Web is first strained from the pommel to the cantle of the tree, and other web crossing those to the bars of the tree on each side, by the straining of these, the hollowness and propriety of the seat is formed. The propriety of the seat is, when the rider without his stirrups, or any effort of his own, naturally settles, and keeps his proper situation in the saddle; but when the seat is improperly shaped, he will be shifted (too forward mostly), and will have an insecure and unpleasant seat. Therefore, when the saddle is on the horse's back, if your cantle is ever so high, the lowest part of the seat should be rather behind the centre of the saddle, where the gravity of the body will settle, and permit the

thighs to keep their proper situation and position.

You will observe, the web sustains the weight of the rider, protecting him from the tree of the saddle, and to render his seat easy, it is first covered with flannel and stuffed with wool; the sides of the seat on each side are stuffed pretty full, to keep the upper part of the thigh clear from chafing, by the edges of the upper flap. The centre covering of the seat is usually hog-skin—some may be induced for their ease to have them covered with doe-skin, but I apprise such, that it is difficult to keep them decently clean; besides, if caught in the rain, they imbibe so much wet, they must be several days drying.

The seat of a lady's saddle, exclusive of the head, is differently formed from the gentleman's. A deep hollowness in the centre of the seat is unnecessary; the seat is stuffed on each side full, that the rider may be less liable to slide to the near side: and particular regard should be had that the saddle be proportioned to the size of the lady; for a tall lady, though ever so slim and light, must not have a short saddle, because she cannot keep herself from off the cantle.

The improvements in the ladies' saddle have, I think, exceeded those of the gentlemen's. If we look at the old-fashioned side-saddle, and the modern one, a great difference appears; but the improvement may not strike the person unacquainted with them. I shall endeavour to point them out.

The modern ladies' saddles, exclusive of the heads, are made high in the pommel; the intention of which is, to prevent the seat from shifting forward, on even ground, or small declivities, which it unavoidably will in riding down steep hills; and when the seat is thus forward, the knee loses its grasp, which is the lady's principal security. The head of the modern saddle, which is the part that receives the knee, is made high (from six to eight inches) which secures the knee from being displaced by any little unexpected roughness, that sometimes unavoidably happens. And lastly, the head is placed more upright, or over to the off side, which assists the lady in keeping her centre in the saddle, and not hanging to the near side. Beside which, the modern saddle has a flap on the near side before the saddle, which preserves the habit from the sweat of the horse, and the leg from the front of the saddle; the inside of this flap is sometimes lined with

flannel for the accommodation of the horse; and the outside with hog-skin, stuffed for the accommodation of the rider. The head, and every part of the ladies' saddle, should be stuffed, to render it as comfortable as possible, but no part should be covered with doe-skin, because, exclusive of the disadvantages I pointed out in the gentlemen's saddle, the ladies' habit will cling to this kind of leather, and ride up beyond a possibility of keeping it comfortably down.

For a lady's stirrup, the slippers now in use are pleasant and secure; the iron cannot gall the instep, nor the foot hang in it in case of accident, provided the iron is wide enough for the foot. My method is to have the stirrup fixed, and hang the leather over the off head of the saddle, the buckle under the head, by which method, I can alter a lady's stirrup without displacing her, or dismounting myself; and thus there can be no occasion for a double-flapped saddle, but all ladies' saddles must have surcingles to confine the flaps.

Other saddles are rarely used now except in riding-houses, which are called peak saddles, and demi-peaks. These saddles have a peak, or raised work, round the seat, shaped to the thighs; the seat is usually covered with stout doe-skin, soft-stuffed and quilted; the peak is continued beyond the tree, a little down the thighs, by leather, the elasticity of which, preserves the balance without galling the thigh.

The demi-peaks have only burs before, to keep the thighs from coming forward, but the full breasted peak has a raised work continued from side to side over the pommel or front of the seat. The peak and adherence of the soft-stuffed doe-skin seat, preserves a secure balance without stirrups, and the breast-work preventing your knees rising or coming forward, certainly gives an additional security to the seat, and therefore, these saddles are preferable for backing young horses, breaking in general, and riding the manege lessons very high. Stirrups are not always used with these saddles, and therefore they are looped to a brass knob fixed over the pommel for that purpose, or removed at pleasure. The skirts of these saddles are usually Russia leather, curiously stitched; in general they make the skirts too short, a fault that is easily remedied by giving orders accordingly. This I look upon to be the ancient war-saddle, and, I believe, is still used in

many parts abroad as a state-saddle, superbly decorated.

**SADDLE-BACKED.** A horse is so termed, when the rump bone rises so high behind, in conformity with the withers before, that a hollow (or rather a complete curve) is formed in the middle, as a natural receptacle for the saddle. Horses of this description are mostly, in action, easy and pleasant to the rider; but they are invariably weaker in the loins than those of an opposite description.

**SADDLE-GALLED.** This is an injury frequently sustained by horses, either in the field with hounds, or in journeys upon the road; and can only happen by the inattention, neglect, or penury, of the owner, in not affording occasional precaution and inspection to the state of the pad, as well as to the first and safe fitting of the saddle. It cannot but be known to the most superficial observer, that the padding of every saddle becomes progressively harder, in proportion to the perspirative matter it absorbs; and, in direct proportion with the hardness it acquires, the greater is the chance of its being injurious to the parts with which it comes into constant contact, and with a burning heat, produced by a long and repeated friction. Injuries of this kind, although originating in the same cause, vary a little in their effects: with one but slightly affected, a warble may be produced; this happens on the side, and if attended to on its first appearance, is easily obliterated by applications of vinegar, or other mild repellents; but, unattended to, and a frequent repetition of the cause being permitted to take place, they soon become sitfasts, and can only be got rid of by instrumental extirpation. Where any part of the saddle-tree (in the central cleft between the saddle pads) is inconsiderately suffered to come in contact with the withers, or vertebræ of the back, and so continues in friction and pressure, during a chase or journey, certain mischief inevitably ensues: in the first, a swelling, formation of matter, and fistula, may be the consequence; in the latter, an excoriation, followed by a tedious wound, or ulcer, may take place.

**SAGACITY.** Upon this subject, we find the following observations, in a treatise upon hare hunting, by an old sportsman.—How common, says the author, has it been with our hasty fraternity, upon the loss of a hare, to swear *she is a witch!* But it is my opinion that a real witch, if obliged to run fair (without the aid of

broomstick or pewter dishes) would not be mistress of half the policy, or be able to devise so many shifts for her life: nor would conjurors, catch-poles, or craftsmen themselves (though furnished with four legs) pursue their prey with so much eagerness, industry, or subtlety, as an old hound.

Every hare is no sooner started than she seems immediately to form a scheme, and to take into it the gravity of the air, the position of the wind, the difference of the soil, the succour of a flock of sheep, and every other accident and advantage that may be most likely to baffle her adversaries and favour her escape. Nor is the experienced hound less acute and crafty, to stop at every double, in order to apprehend her where she squats; to try every bye path, gate, or gutter hole, to round it on the side where she seems to bend; to proportion his speed to every degree of alteration in the scent or sinking of the chase. He seems also, with no less curiosity, to distinguish the scent he is engaged in from any fresh offer, as well as to discern and pick it out, as often as she repeats the foiled path.

It is very common for a hare to run a mile or two forward, and then, making a small ring, to fly back in the same track, whilst her enemies are puzzling at the head of her works: and I have been several times an eye witness, continues the writer, of her beating about and thrusting out a fresh hare in her place, and then saving herself by a swift retreat, and two or three large leaps, the better to impose on the eager dogs. I have also seen an old dog, on the like occasion, standing to his scent, looking over his shoulder, and, as it were, scolding at his heedless juniors for going on so eagerly, or for changing their game. A hundred more of this sort of observations you may hear from any old weather-beaten huntsman over a bottle of *October*.

It remains then, that we consider the grounds of all this sagacity (so called); that we more strictly examine into the hidden principles of all these actions, and inquire into the powers and faculties given by the great Creator for such astonishing operations.

Shall we believe with the vulgar, that all this is properly the effect of *thought*, *reflection*, and *ratiocination*? Or shall we maintain, with the schools, that a soul merely sensible (without any reason or thinking faculty) is capable of it? Or, finally, shall we dare to suppose or

suggest, (with the exploded Des Cartes,) that these are the operations of mere matters of machines, not less destitute of sense than reason? If I should pretend to defend the first of these opinions, I draw upon me the philosophers and diviners. The least word in favour of the last, will make my jolly brethren, and all the fair sex, (in behalf of their favourite pugs and grimalkins,) outrageous with me; but to rest content with the middle hypothesis (the sensibility of brutes) is to be at war with my own reason, and to be guilty of the grossest absurdity of the three. But let us examine them severally.

A good number of the sages have served themselves, and perhaps satisfied their readers, with the word *instinct*, which (together with its learned brother, *occult quality*) is not a jot more than an evasion of the question, a mere covert for ignorance.

We might, much better, honestly make confession of our ignorance, and end all dispute. But we must then quit the name of philosophers. For, of what use is such a term as instinct in the inquiry before us, when there is no idea annexed to it? And how ridiculous is it to offer to explain one thing by another less intelligible than itself? Let the question be put, what is it that excites the hound to pursue the hare? The answer is ready.—It is natural instinct. And those who feel themselves satisfied or enlightened by it, need read no further.

Perhaps the Omnipotent has given faculties to these, his creatures, that are beyond the reach of short sighted man! Be it how it will, as often as we presume to inquire into his stupendous works, and to give a rational account of his ways and proceedings with his creatures, we must set about it with such measures as we have, and make use of such terms as we understand, and are agreed upon.

Is it then reason that is the spring of action in the brute creation? and shall we allow them those powers of remembering, relating, distinguishing, compounding, numbering, inferring, approving, comparing, choosing and resolving, which we feel in ourselves? But we must venture to deny that their motions and actions have the semblance of *reasoning*; at least, of such as human reasoning, and of no other have we an idea.

They act, indeed, or are rather acted on, with a just regularity to the ends of their formation; but that very exactness

and regularity is an argument that their motions are not spontaneous; that they are not the effect of thought, choice, and discretion. Among rational creatures (who have choice and liberty) there are fools and madmen; such as mistake their objects, or their way towards them; such as act contrary to the designs of their creation; choose evil for good, and pursue their own destruction. But these thoughtless animals generally are impelled, with an immutable constancy, to the ends of their being; to the preservation of themselves, and the propagation of their species. All their motions are directed to a few ends, for which they were particularly created; and in other respects, they appear almost as stupid and senseless as trees and plants.

The hare seems to have a foresight of the weather; and is more or less ready to rise and steal off, or to sit close, in prudent proportion to the imminent danger of being hunted by the scent, or followed by the trace. If this be knowledge, what astronomer, after all his gazing, is so deeply learned? But the same creature is yet so utterly insensible of her condition and safety, that she goes loitering to her seat late in a fine morning, and makes her last double in a dirty path, as if she had a design to be hunted home; or to give the unmerciful huntsman a description of the avenues to her house. Both these actions are agreeable to her nature, (performed by young and old; those sitting under a kennel wall, and those that never heard the tongue of a dog).

The hound also, in searching for his game, as well as in pursuit of it, is as cunning as the old serpent; yet he is perfectly without apprehension of his own approaching ruin; and contentedly offers his neck to the same rope in which his brother was just hanged before his face.

The most skilful architect or mathematician, with all his dexterity, cannot equal the art of a bird in making her nest: yet will the sagacious builder starve upon eggs that are not her own; or purvey for a young one that is an enemy to her species, and which will ungratefully devour its foster parent. Thousands of instances might be added by way of illustration, but they are unnecessary.

Reason, as far as we know any thing of it, is active and self moving; not like dull matter, confined to objects; but at liberty to turn and apply itself to any object presented to it. Reason has the essential power to perceive, to collect, re-

## S A L M O N

posited, and carefully covered by the parent fishes, who afterwards hasten to cleanse and recover themselves; (the male loses the gristle at the jaw;) for, after spawning, they become very poor and lean, and then are called kipper. At their first entrance into the fresh water, salmon are observed to have abundance of insects adhering to them, especially above the gills: these animals denote the fish to be in high season, and die and drop off soon after the salmon's leaving the sea.

The spawn lies buried until spring, and, without any other care, is nourished and brought to perfection, if not disturbed by violent floods; or by the depredations of other fish, of which the eel, roach, dace, and grayling, are dangerous neighbours. About the latter end of March the young begin to come forth, and gradually increase to four or five inches in length, when they are termed smelts or smouts; about the beginning of May, the river seems to be alive, and there is no forming an idea of the numbers without seeing them. A seasonable flood, however, hurries them to the sea, very few being left in the river; about the middle of June, the earliest of the fry commence their return from the sea into the river, (at that period from twelve to sixteen inches long,) and progressively augment in number and size, until about the end of July, which is at Berwick termed the height of the gilse time (the name then given to the fish of that age). Early in August, they lessen in number, but advance in size, some being from six as high as nine pounds weight: this increase appears surprisingly quick, yet a gentleman of Warrington has given an instance of still more rapid growth: a kipper salmon, weighing seven pounds and three quarters, taken on the seventh of February, was marked with scissars on the back fin and tail, and turned into the river; he was again taken on the seventeenth of the following March, and then weighed seventeen pounds and a half. In this case, the remark of Walton seems to have been more than verified, "that the samlet becomes a salmon in as short a time as a gosling becomes a goose."

All fishermen agree that they never find any food in the stomach of the salmon, which is certainly a fish of prey, having teeth in his mouth as other fish of prey have, and delighting to pursue and seize small fish: it is, however, very remarkable that, although a salmon be taken in the very act of chasing and catching the small fry, yet upon being opened nothing of that nature will be found within it, neither has it ever been discovered by opening these fish, what they do subsist upon. It is likely they may neglect their food entirely during the time of spawning, as sea lions and sea bears are known to do for months together, during their breeding season; and it may be observed that, like those animals, salmons return to the sea lank and lean, and come from the salt water in good condition. It is evident that their food is both fish and worms, for the angler uses both with success, and also a large gaudy artificial fly, which, probably, the salmon mistakes for a gay libellula, or dragon fly.

Scotland possesses numbers of fine fisheries on both sides of that kingdom.

## S A L M O N

Ireland (particularly the north) abounds with salmon : the most considerable fishery is at Cranna, on the river Ban, near Coleraine. The nets used are eighteen score, or 360 yards long, and are continually drawing night and day the whole season (nearly four months), two sets of sixteen men each, alternately relieving one another ; the best drawing is when the tide is coming in.

The salmon are cured by being first split, and rubbed with fine salt, and after lying in pickle in great tubs or reservoirs for six weeks, are packed up with layers of coarse brown Spanish salt in casks, six of which make a ton ; these are exported to Leghorn and Venice. Salmon dried are also sent to the London as well as foreign markets, and are sold (under the name of kippered salmon), at the former from nine to fifteen pence per pound. The mode of preparing the dried salmon is as follows :—they are split down the chine, laid open, and salted for many days ; then tied up by the head, and hung in an airy place, shaded from the sun, until quite dry. They are dried with the head upwards, that the essential oil, and the juices of the fish, more abundant in the jole, and on which its true flavour depends, are thus preserved in its interior substance : in a contrary position it would, from the head, soon be lost, and much injure its preservation : if not in warm weather even prevent its cure.

The salmon may justly be termed, among fresh water fish, the superior of the rivers, both from its size and excellence ; it is, however, so universally known, that a brief description will serve : it is handsome in its make, the head small, with a sharp pointed nose ; the colour of the back and sides are grey, frequently spotted with black, sometimes plain, the covers of the gills are subject to the same variety, the belly silvery, (the female may be distinguished by having a longer snout and the scales being more dull, the flesh is said likewise to be drier, of a paler red, to have less flavour, and, according to Walton, she is of inferior size ;) the teeth are lodged in the jaws and on the tongue, are slender but very sharp, the body is longish, and the tail a little forked.

The purging of the salt water is so essential to the salmon, not only in cleansing them from their impurities after spawning, but from every other, acquired by their feeding all the summer in fresh water, that if any are prevented by weirs, &c. from reaching the sea, their heads augment, their bodies waste, and they pine away by degrees, and die for want of it : the porpoises are, however, their great enemy, and for fear of them they are cautious of entering too far into the salt water, therefore keep about the bays near the entrance of rivers into the sea, and this may in some measure account for what has often been asserted, “ that salmons always re-enter the same river in which they had been bred.”

The largest salmon Mr. Pennant ever heard of, weighed seventy-four pounds. In September, 1795, one measuring upwards of four feet from nose to tail, and three in circumference, weighing within a few ounces of seventy pounds, was sold at Billingsgate, and was the largest ever brought there : it was bought by a fishmonger in the Minories, and sold by him at one shilling a pound. The Severn

## S A L M O N

salmon are much inferior as to their bulk ; for one taken near Shrewsbury, in 1757, weighing only thirty-seven pounds, is recorded in the British Chronologist, as exceeding in length any ever known to have been taken in that river, and being the heaviest, except one, ever remembered in that town. They have in many parts been caught by angling with an artificial fly, and other baits, upwards of forty pounds weight.

The salmon delights in large rapid rivers, especially such as have pebbly, gravelly, and sometimes weedy, bottoms, and, when feeding, generally prefers the rough and upper parts of gentle streams, and the tails of large ones ; after their feeding time, they retire to the deep and broad water, and swim very fast, usually in the middle of the river near the ground, and more at night than in the day, resting at convenient places, under bushes, weeds, banks, or stones, and then the whole shoal run again. Salmon bite best from six until eleven in the forenoon, and from three in the afternoon until sun-set, especially when there is a moderate breeze upon the water ; the chief months to angle for them are March, April, May, and June, although they will take a fly until October, but they are then out of season ; they are to be fished for with lob-worms and minnows, but a large artificial fly is the most killing.

The rod should not be less than fifteen feet, longer according to the breadth of the river ; limber, yet strong, with wire rings from the top to within three feet where the reel is fixed, with a good running line, without knots, made of either silk or hair (the former is to be preferred), and the reel must be large enough to contain four score yards, or at least as much as will reach more than across the river fished in. Wherever the running line is directed, the reel is proper to be used ; they are of various sizes, and may be proportioned to the coarseness or fineness of the line. The being enabled to give the salmon, when hooked, plenty of line, is of great advantage to the angler ; for the fish will at first run swiftly, and afterwards leap and plunge, so that he must be humoured, and the line slackened and wound up again with great skill, until he is quite subdued, when he may be led to some shallow, where, on his belly touching the bottom, he will turn on his side, and be so jaded, that he may be taken out by the gills. Salmon anglers, however, are generally provided with what is called a gaff, which is a stick something pliable, with a large barbed hook at the end, and which can be thrust into the head or gills of the fish, to lift him from the water ; for which purpose a landing-net is too small.

The line from the reel, after being run through the rings, is to be joined to the foot or gut length, which must be looped at each end, the one to fasten it to the reel line, the other to the fly ; this foot-length must be made of three strong silk-worm guts twisted together, three lengths will be sufficient, as only one fly is used ; the link to which the fly is fixed should be looped on the same way, for the convenience of changing it, if the fish refuse one sort of fly, and another is wished to be tried.

In trolling for salmon with minnow or grayling, the foot-length or

## S A L M O N

links must be about three yards, with a swivel or two, as well to help the bait's playing freely, as to prevent the line from twisting and breaking ; a large shot or two, about a foot from the bait, will keep it under water when played, and which may be either added to or diminished, according to the strength of the current, (for this kind of angling is chiefly in the streams, and is best when the water is clearing off after a fresh, or when upon the rise, before it becomes too thick.) The rod must have a stiffer top than for fly-fishing ; the hook large, and long in the shank, with a very small one fixed above, at nearly the distance of the length of the fish baited with ; the bait is to be drawn upon the hook like a worm, by putting it into the mouth, and bending it round the curve of the hook until it comes out a little above the tail, so as to keep the tail a trifle bent ; the small hook (which should be made blunt at the point) must then be put through the lips of the fish, to prevent its slipping into the bend of the large one. Some use a leaded, and others a snap, hook ; but the above method is preferable. When thus prepared, the line should be let out from the reel, about the length of the rod ; the bait thrown across the stream, and the line drawn with a pretty brisk motion up it, which causes the bait to spin well, and entices the large fish to take it. Some anglers strike salmon as they seize the bait ; but it is the surest way to let them go down with it for a time : those who use themselves to strike immediately, should be careful, when a salmon runs at the bait, not to snatch it away through surprise before he takes it, as is often done even by tolerable anglers.

In fishing for salmon with lob worms, the trolling tackle is to be used, and two of these worms well scoured, put on the hooks ; the first should be drawn quite above the top of the shank of the large hook, and the small one run through its head ; the second worm is to be run some way above the shank, and drawing the first down, let them hang with their tails one above the other, preventing the point of the large hook from appearing through the worm ; lay in the worms at the bottom of a stream, holding the rod still, and keeping as much as possible out of sight : if in a short time there is no bite, move the line gently up the current, and the worms will play and shew themselves by means of the swivels, and thus allure the salmon to take them ; if no success follows after a few trials, seek another stream, and there repeat them. This mode is to be used when either the water is too much discoloured for the artificial fly, or when the day is bright, with scarce any wind stirring, and the water so clear, that the salmon can discover the deception of it ; they can be taken by no other method of angling than this and minnow fishing, when the weather and water are in such a state.

Another way of fishing with lob worms for salmon, is to run the hook through the middle of a lob worm well scoured, and pull it above the shank ; then take a second, and put the hook in an inch below the tail, drawing it on the hook about three-fourths of the length ; the head of the worm being at its point, then draw down the first to the latter worm : a piece of lead with a small hole through it (which is called a plumb), must be fastened upon the line two feet

## S A L M O N - F R Y

above the hook ; by which means the bait can be kept in any certain spot, and pulling the line tight, the plumb will be felt at the bottom, and the current will give motion to the bait with the link below it ; when the bait has remained a few minutes, gently move it about a yard up the stream, and again let the plumb rest at the bottom ; this will excite the attention of the fish, and frequently tempts them to seize the worms.

A third way, is with four (or more) worms : put the hook through three of their heads, and pull them upon the line ; the last should be the largest, and the hook is to be thrust in an inch below the tail, and his head to cover its point ; the rest of the worms upon the line are to be slipped down to the shank of the hook, but not upon it ; the worms will then play around the hook in a way the most alluring to attract the salmon. In trout fishing, this plan of fixing the worms is stated to have been very successful, and when only one worm is used, the same gentleman directs the hook to be inserted at its head, and the tail left to play at the end of the hook.

Mr. Bingley, in his *Animal Biography*, notices salmon hunting, as it is termed, and practiced by a man named Graham, in the north. When the tide recedes, what fish are left in the shallows, are discovered by the agitation of the water : this man, with a three-pointed, barbed, spear, fixed to a shaft fifteen feet long, plunges into these pools at a trot, up to the belly of his horse. He makes ready his spear, and when he overtakes the salmon, strikes the fish with almost unerring aim ; that done, by a turn of the hand, he raises the salmon to the surface, wheels his horse towards the shore, and runs the fish on dry land, without dismounting. He has killed from forty to fifty fish in a day ; ten are, however, no despicable booty. His father was probably the first person that ever adopted this method of killing salmon on horseback, and who was in October, 1811, living at Fish-house, in the parish of Dornock, near Gretna Green ; and, although ninety-eight years of age (armed with a trident, and on horseback) was so dexterous, as to strike and bring out of the water, a salmon of considerable weight.

SALMON-FRY, called in some counties samlets, salmon-pinks, salmon-smelts, &c. are by some said to be found in all rivers frequented by the salmon, and to be the produce of the spawn left by them. According to Mr. Pennant, the samlet is the least of the trout kind ; is frequent in the Wye, in the upper part of the Severn, and the streams that run into it, in the north of England, and in Wales : it is by several imagined to be the fry of the salmon ; but Mr. P. dissents from that opinion, for the following reasons :

First, it is well known that the salmon-fry never continue in fresh water the whole year ; but, numerous as they appear on their first escape from the spawn, the first vernal flood that happens sweeps them into the sea, and leaves scarcely one behind.

Secondly, the growth of the salmon-fry is so quick, as suddenly to exceed the dimensions of the largest samlet ; for example, the fry that have quitted the fresh water in the spring, not larger than gudgeons, return into it again a foot or more in length.

Thirdly, salmon attain a considerable bulk before they begin to breed ; the samlets, on the contrary, are found male and female (distinguished by the milt and roe, although it has been a vulgar error to believe that there were no other than males of this species,) of their common size.

Fourthly, they are found in the fresh waters in all times of the year, and even at seasons when the salmon-fry have gained a considerable size.

**SALMON TROUT.** This fish differs from the salmon in so many particulars, that the fishermen distinguish them at first sight, and all agree that they are a distinct species. It is not peculiar to the northern rivers, though perhaps most numerous there, as the fishermen will take five or six for one salmon or gilse, and do not value them at half the price.

The salmon trout is handsome in its form, is more richly adorned, and is longer, thicker, and rounder in proportion than a salmon ; the scales are small, beautifully intermixed on both sides of the lateral line, and also the covers of the gills, with spots ; the fins are strong, and the tail shorter, but not so much forked, as the salmon's ; the flesh is exceedingly rich, and in some countries better esteemed than any fish of the salmon kind ; they are generally from two to six pounds weight, some run larger ; they are often taken when angling for salmon or large trout, their haunts being the same. Early in the spring they enter the rivers, are in prime season from the end of April until July, and spawn chiefly in September ; but that period varies in different waters : the rod should be as for salmon, the reel line strong, and foot-length about three yards, of fine twisted silk-worm gut, or the strongest single, with the knots well whipped. When the water is clear enough, the baits should be large gaudy flies ; if discoloured, well scoured worms, with which, having a running line, angle in or near the sides of streams, with a shot or two, fifteen inches from the hook, which should be No. 3, or 4. This is a strong fish in its element, and therefore, when hooked, plenty of line must be given.

**SALTRAM.** A brown horse, foaled in 1780, bred by, and the property of, John Parker, Esq. (afterwards Lord Boringdon) of Boringdon, Devonshire, sold to his R. H. the Prince of Wales.

Saltram was got by Eclipse, his dam, Virago.

At Newmarket Craven Meeting, 1783, Saltram won a sweepstakes of 300gs, each 8st. A. F. (3 subscribers) beating Mr. Douglas's colt, by Justice, out of Ceres's dam :—2 to 1 on Saltram. At Epsom, May 29, he won the Derby stakes of 50gs h. ft. for three years old ; colts, 8st. fillies, 7st 11lb. last mile (34 subscribers,) beating Colonel O'Kelly's Dungannon, Mr. Walker's Parlington, Duke of Queensberry's Gonzales, Colonel O'Kelly's Cornet, and Mr. Davis's Phenomenon :—5 to 2 against

Saltram, 5 to 2 against Cornet, 5 to 1 against Dungannon, 8 to 1 against Gonzales, 10 to 1 against Parlington, and 20 to 1 against Phenomenon. In the first October Meeting, at 8st. he received 50gs compromise from Lord Egremont's Rinaldo, 8st. 7½lb. D. I. 500gs. h. ft.

At Newmarket second spring meeting, 1784, Saltram beat Lord Foley's Oliver Cromwell, 8st. each, R. M. 100gs :—5 to 4 on Saltram. He was afterwards sold to his R. H. the Prince of Wales.

At Newmarket first spring meeting 1785, Saltram, 8st. 6lb. won a sweepstakes of 200gs. each, h. ft. Ab. M. (4 subscribers) beating Lord Clermont's Cantator, 7st. 2lb —Even betting. This was the last time of his starting. He was afterwards a Stallion, and covered at Aston Clinton,

Hertfordshire, in 1789, at 16gs and afterwards in Surrey.

Saltram was sire of Mr. Dymock's Tiffany, Prince of Wales's Caroline, St. David, Queen of Sheba, and Whiskey, Lord Grosvenor's Sylph, Duke of York's Laurestina, sister to Laurestina, Rose, and Spankaway, D. of Bedford's Sprightly, Lord Clermont's Sweeper, Mr. Bullock's Royalist, Mr. Turner's General, Oscar, and Henrietta, Mr. Broadhurst's Clytus, Mr. Rutter's Coal-Merchant, Mr. Dilly's General, Mr. Wyndham's Tearcoat, Mr. Delme's Peeping Tom, Sir H. Williamson's Septem, Mr. Hyde's Comer, Mr. Durand's Whip, &c. &c. all winners, also of the dam of Royala, Piscator, Scar; of the dam of Miss Hayes, afterwards Modesty, Harriet, Master Richard, Alfana, Cacomba; of the dam of Lady of the Lake, Sir Tooley Whagg O'Shaughnashine, &c. besides many others.

**SAMPSON.** A black horse, foaled in 1745, bred by James Preston, Esq. and sold to Mr. Robinson of Malton, Yorkshire. Sampson was got by Blaze; his dam, (Baboon's dam) by Hip, his grandam by Spark, (son of the Honeycomb Punch;) great grandam by Mr. Lister's Snake out of Lord D'Arcy's Queen.

In 1750, Sampson won £50 for five year olds, at Malton, beating, at three heats, Mr. Hunt's Jigg of Jiggs, who won the first heat from Sir William Middleton's Thwackum, Mr. Croft's Red Robin, Mr. Langley's Star, &c.; and the subscription purse of £50—four miles, at Hambleton, beating Thwackum, &c.; he also won the king's plate at Lichfield, beating, at three heats, Mr. Martindale's Gustavus, Lord Gower's Jubilee Dickey, and four others; Gustavus won the first heat from Jubilee Dickey, and Sampson the two following heats from Gustavus. At Newmarket in April, 1751, he won the subscription plate or purse of £50, weight 10st. beating, at two heats, Lord Portmore's Oroonooko, Mr. Panton's Drudge, and Lord Gower's Squirrel.—The first heat was a long time very severely disputed at the rising ground at the running up to the ending post, between Sampson and Squirrel, when the superior strength of the former prevailed, to the great joy of the Yorkshire gentlemen who had large sums of money depending on him. The bets at starting, were gold to silver on Sampson, and after the heat, even money against him, owing to Drudge (who was sold, a short time before starting, to Sir Edward Hale for 350gs,) not running for the first

heat, and who was expected to have made a better figure than he did. Sampson afterwards walk'd over for the king's plates at Winchester and Salisbury; won the king's plate at Canterbury, beating, at two smart heats, Sir Edward Hale's Drudge; also the king's plate at Lewes, beating, very easy, Sir Charles Goring's Tom Thumb, by Goldenlocks; and walk'd over for the king's plate at Newmarket, in October; where, in April following, he started against Thwackum for the King's plate, when Sampson won the first heat, but not very easy, though the odds were then 8 to 1 in his favour; the second was a remarkably fine heat, which Sampson lost, with the mortification of being whipped for the first time; and the last heat was closely contested for the whole four miles, and allowed to be the finest that had ever been run between two horses. The above were the only times of Sampson's starting; and the reason assigned for his being beat, was, that his eye-sight (at all times tender) particularly failed him after the first heat; a conjecture not ill-founded, as he had beat Thwackum when they met before this last race, tolerably easy.—Sampson was rode by John Singleton, and Thwackum by Thomas Jackson, who both proved themselves to be excellent and judicious riders.

Sampson then became a public stallion at Malton, Yorkshire; and afterwards a private one in Lord Rockingham's stud, where he died in the year 1777, aged 32. He was sire of Engineer, Bay Malton, Treasurer, Pilgrim, Cosmo, Solon, Phocion, Plantagenet, Dauphiness, Flounce, (Nottingham's dam) and several others.—He got the dam of Miss Cornforth, that bred Ormond, Miss Tippet, &c. He was also sire of Mr. Edward Carter's old Mare, that bred Mayfly, Blackbird, and his R. H. the Prince of Wales's Tot, that won the gold cups at Richmond and Doncaster in 1789.

Sampson was 15 hands 2 inches high; The dimensions of his fore-leg from the hair of the hoof to the middle of the fetlock joint, 4 inches; from the fetlock joint to the bend of the knee, 11 inches; from the bend of the knee to the elbow, 19 inches; round his leg below the knee, (narrowest part) 8½ inches; and round his hind-leg, (narrowest part) 9 inches.

The above was taken by the late Lord Rockingham himself.

Sampson was the largest boned blood-horse that ever was bred, and the gentleman who communicated the above, observes, that he has tried a great number since, but has not found one to equal him.

**SANDCRACKS.** A defect in the horse's foot. They consist of a separation of the fibres of the hoof in a perpendicular direction. If they extend to the coronet, they are extremely troublesome to cure. Those horses are most liable to them that have either strong and brittle hoofs, or narrow heels. Blood horses are more subject to them than inferior horses.

In the treatment of them, Mr. Denny says, the part around the crack must be rasped thin. The firing iron should be drawn above and below it to the extent of the fissure, in order to prevent its extension. The iron should also be carried over the crack, by which means a slight degree of moisture will exude, and glue up the part; which may be covered with some of the following ointment, spread on tow, and secured by a bandage.

Take Ointment of marsh-mallow, two ounces;

Common turpentine, one ounce.  
Mix.

The horse must have a bar shoe, which will rest firmly on the frog, and be hollowed in the part which is opposite to the seat of the disease, so that no pressure may be made on that part of the foot. Rest should also be allowed for a few days; and after this, only moderate exercise permitted, until the fissure has descended towards the inferior part of the foot.

Besides this, we are advised to bathe the coronet and hoof twice a-day with the following, in order to promote the growth of the horn from the coronet.

Take Ointment of marsh-mallow,  
Barbadoes tar, of each three ounces;

Spirit of turpentine, one ounce.

Mix and make the embrocation.

**S C A B.** The disorder in horses so called, is the species of mange become inveterately dry and scabby by its long duration.

**SCALDING**, a name given to some caustic remedies applied hot. Gibson speaks of a compendious way of curing the poll-evil, where there is an exceedingly bad disposition, and a very great foulness, by scalding, as the farriers term it. Several, he says, succeed very well in it. The manner is as follows:

Take of Corrosive sublimate,

Verdigrise in fine powder,

Blue vitriol, of each two drachms;

Green copperas, half an ounce;

Honey, or Ægyptiacum, two ounces;

Oil of turpentine,  
Train oil, of each eight ounces;  
Rectified spirit of wine, four ounces.

Mix these together in a pint bottle for use.

Some make their scalding mixture milder, by using red precipitate instead of sublimate, and white vitriol instead of the blue; others leave out the train oil, and use only oil of turpentine and linseed oil, which makes but little alteration; and some use the following with good success:

Take of Verdigrise, half an ounce;

Train oil, half a pint;

Oil of turpentine, four ounces;

Oil of vitriol, two ounces. Mix.

The manner of scalding is first of all to clean the abscess very well, with a piece of sponge soaked in vinegar and squeezed. Then put a sufficient quantity of the mixture into a ladle with a spout, and when it is made scalding hot, pour it into the abscess, closing the lips together with one or more stitches in proportion to its size. This is to remain so for several days, and if good matter appears, and not in an over great quantity, it will soon do well without any other dressing besides bathing with spirit of wine. But if the matter begins to flow in great abundance, and of a thin viscid consistence, it will require to be scalded a second time or oftener, if the same disposition continue. The corrosive ingredients, whereof these liquid mixtures are compounded, would be harsh to human flesh, but agree very well with horses, whose fibres are more rigid; and therefore such sharp applications help greatly to contract the vessels. This method of proceeding is chiefly useful when the poll-evil happens to be the crisis of an acute fever, or when it happens to horses that have been surfeited, or under some other chronical disorder; for in all cases proceeding from common accidents, cleansing tinctures and fresh dressings will do the business.

Here our author subjoins the case of a horse that was cured of a poll-evil by scalding. "In this," says he, "are some very extraordinary circumstances that will give further light into the nature of this malady, and the method how such cases ought to be treated, especially when they proceed from some previous sickness, which is often the cause of a poll-evil, though hitherto not much attended to by practitioners.

This was a young troop horse that had been pampered for sale, and had fallen into a very dangerous fever, attended with

a great stupor and heaviness, with a total loss of appetite, and a loathing of his food. The animal had but little relief till a large critical swelling arose on his poll, at first about the bigness of a penny loaf, but in a few days it grew to a much greater size, for the weight of it made him stoop his head as low as his manger, and by degrees the swelling grew so prodigiously that his muzzle came within a few inches of the ground, and rose so suddenly all along his neck, and down to his shoulders and fore-legs, that it was impossible to raise his head above a foot from the ground. His neck measured above a quarter of a yard broad over his mane, his shoulders were blown up to a monstrous size, like some horses that have been staked under the arm. Indeed he grew to such a spectacle, that all who saw him thought it was impossible he should recover. One thing, however, was much in his favour; for, as the swelling increased, his appetite grew better; and while he continued in that posture with his mouth to the ground, which was about three weeks before the tumour broke, he ate his whole allowance of hay every day, which was laid down before him a little at a time, and licked up bran and oats out of a flat basket, as much as was sufficient for a horse in health, that did no business; and drank plentifully of water-gruel, which was given by holding about half a pailful at a time, edgeways, that he might get his head into it. When the tumour broke, it discharged a very large quantity of curdled matter at first, which soon changed to a viscid dusky slime; the orifice was on one side near the occiput, though the matter had also a drain from the other side, and continued running for about a month or five weeks, in very great quantity, before the swelling of his neck and shoulders came down, and before he came to the free use of his neck and limbs. The running by this time was much abated, but the matter still of no good consistence; and therefore having now no other disorder besides the abscess, and that reduced to a moderate compass, I caused it to be laid open, and the part scalded in the manner already described. I deferred opening it all this time, though I was much solicited to do it sooner; for I found by this delay the fever was entirely removed, and the distemper confined wholly to a single part: whereas, if it had been laid open sooner, the symptoms might again

have been renewed, the discharge been less perfect, the swelling of the neck and shoulders would not have come down so well, nor the malady have been so completely removed, either by applications to the part, or by artificial drains and issues of any kind. After the first scald, the matter was small in quantity, and looked well; but in ten days, it began to look thin and of a dirty colour again, so that I caused him to be scalded a second time, after which it healed up, and he had three or four doses of purging physic, and some antimonial powders, given him; but the part being still weak, and the horse naturally full of motion, especially with his head, it swelled again some months afterwards and broke; which accident proceeded from this, that the muscular flesh was wasted more on one side of his pole than on the other, which gave some restraint in pulling down his head, and consequently caused fresh pain till the flesh grew, and that the muscles on both sides came to their proper equilibrium: and, though it broke out again once or twice afterwards, yet the swelling was only like a large marble, the matter was good, and did not continue running above two or three days. And about a year afterwards, the flesh on one side was grown equal to the other, and the horse continued sound and useful many years without any visible mark or deformity.

SCENT. Upon this depends all the hopes and pleasures of the sportsman. Scent is an effluvium, which, in a greater or a less degree, is continually issuing from the bodies of animals, and other substances; or, in other words, it consists of that animal exudation by which a dog is enabled to inform his master of his approach to game. The effluvium constantly issuing from the pores of all animal substances, consists of minute particles or corpuscles, which, driven by the wind, or otherwise, and coming in contact with the olfactory nerves of the dog, enable him to discover the proximity of the object of pursuit; and, after having ascertained the direction of the vapour, he cautiously ascends, as it were, the stream, and, by practice, becomes a proficient in pointing out the identical situation of the source whence the effluvium or scent issues; and a pointer or setter thus prepares his master for the springing of the game.

Thus sings Somerville:—

Should some more curious sportsman here inquire,  
Whence this sagacity, this wond'rous power

Of tracing, step by step, or man or brute?  
 What guide invisible points out the way  
 O'er the dank marsh, bleak hill, and sandy plain?  
 The courteous muse shall the dark cause reveal.  
 The blood, that from the heart incessant rolls  
 In many a crimson tide, then, here and there,  
 In smaller rills parted, as it flows  
 Propell'd, the serous particles evade,  
 Through th' open pores, and with the ambient air  
 Entangling mix, as fuming vapours rise,  
 And hang upon the gently purling brook,  
 There, by the incumbent atmosphere compress'd,  
 The panting chase grows warmer as he flies,  
 And through the net-work of the skin perspires;  
 Leaves a long steaming trail behind, which, by  
 The cooler air condensed, remains, unless  
 By some rude storm dispersed, or rarefied  
 By the meridian sun's intenser heat.  
 To ev'ry shrub the warm effluvia cling,  
 Hang on the grass, impregnate earth and skies.  
 With nostrils op'ning wide, o'er hill o'er dale  
 The vig'rous hounds pursue; with ev'ry breath  
 Inhale the grateful steam; quick pleasures sting  
 Their tingling nerves, while they their thanks repay,  
 And in triumphant melody confess  
 The titillating joy. Thus, on the air  
 Depend the hunter's hopes.

Beckford observes—"I cannot agree with Mr. Somerville in thinking scent depends on the air only. It depends also on the soil. Without doubt, the best scent is that which is occasioned by the effluvia, as he calls it, or particles of scent, which are constantly perspiring from the game as it runs, and are strongest and most favourable to the hound, when kept by the gravity of the air to the height of his breast; for then it neither is above his reach, nor need he stoop for it. At such times, scent is said to lie *breast high*. Experience tells us, that difference of soil occasions difference of scent; and on the richness of soil and the moderate moisture of it, does scent also depend, I think, as well as on the air. At the time leaves begin to fall, and before they are rotted, we know that the scent lies ill in cover.—This alone would be a sufficient proof that scent does not depend on the air alone. A difference of scent is also occasioned by a difference of motion; the faster the game goes, the less scent it leaves. When game has been ridden after, and hurried on by imprudent sportsmen, or has been coursed by sheep dogs, the scent is less favourable to hounds; one reason of which may be, that the particles of scent are then more dissipated."

But we are of opinion, that although Somerville is perfectly correct, Beckford is

not absolutely wrong; Somerville has considered it in a philosophical manner, while Beckford, as a practical sportsman, has stated what has presented itself to him, and has noticed the cause rather than the effect. However, that scent must always depend on the state of the atmosphere, a very few words will clearly shew. From what has been already stated, it will be easily perceived, that scent is a sort of fluid, the continuance or dispersion of which must depend on the state of the atmosphere: thus the keen air which generally blows from the north or east dissipates the scent, and every sportsman is aware that when the wind blows from the quarters just mentioned, the scent is seldom good. With the soft air from the south, the case is different; at such times, it would appear that the atmosphere is in that state which prevents, as it were, the escape of the scent; or, in other words, the particles constituting scent, which escape from the animal, then become thick and heavy, and fall, on issuing from the animal, upon the ground, or adhere to the blades of grass, or other obstacles with which they come into immediate contact, and a considerable time generally elapses before they become dispersed, unless, indeed, a sudden alteration in the weather takes place. Beckford's observation respecting the scent lying breast

high, although a generally received opinion, appears to us, nevertheless, an erroneous notion altogether. He says, that when the scent, "by the gravity of the air, is kept to the height of the hound's breast, it is neither above his reach, nor is it necessary he should stoop for it. At such times, scent is said to lie *breast high*." The fact is, that at such times when hounds run with so good a head, the scent falls, rather than rises, to the height of the dog's breast; it is not able to rise, or it would be very quickly dissipated. Whenever, therefore, hounds run *breast high*, the particles of scent appear to condense, and are of course thus rendered more cognisable by the olfactory organs of the dog.

As to scent depending on the nature of "the soil," this also is a position that requires elucidation. It is well known that upon fallows or hard roads, the scent is never good, unless, indeed, the state of the atmosphere is such that the particles of scent condense and fall upon the ground, when hounds are able to carry the scent tolerably well upon such places; and we make no doubt, most sportsmen have observed that the scent over fallows and upon roads varies very considerably. In pasture fields, and other places, where obstacles interpose and arrest the particles of scent in their progress, the scent will be good, and for the same reason the scent is always good in cover. In respect to a rich soil yielding a better scent than poor ground, this arises from the circumstance of its being better and more thickly covered with vegetation, and consequently opposes numerous obstacles to arrest the particles of scent; while a poor soil, by being more thinly clothed, and often almost bare, of course, cannot present the same detainers to the progress of the scent; and, consequently, the hunting over such ground is more difficult for hounds. But to shew more clearly that such is the state of the case, it may be observed, that in those places bordering on heathy mountains, whenever a fox happens to make for the hills (where heath is growing) the scent is always uncommonly good, from the circumstance that a great number of obstacles are presented, to which the floating particles, called scent, adhere.

Even the following remarks of Beekford himself, seem to prove the correctness of the preceding observations:—he says, "I believe it is difficult to ascertain what scent exactly is; I have known it

alter very often in the same day; I believe, however, it depends chiefly on two things, the condition the ground is in, and the temperature of the air; both of which, I apprehend, should be moist without being wet: when both are in this condition, the scent is then perfect; and vice versâ, when the ground is hard and the air dry, there seldom will be any scent. It scarcely ever lies with a north or east wind; a southerly wind, without rain, and a westerly wind that is not too rough, are the most favourable. Storms in the air are great enemies to scent, and seldom fail to take it entirely away. A fine sun-shiny day is not often a good hunting day; but what the French call *jour des dames*, warm without sun, is generally a perfect one. In some fogs I have known the scent lie high; in others, not at all; depending, I believe, on the quarter the wind is then in. I have known it lie very high in a mist, when not too wet; but if the wet hangs much on the boughs and bushes, it falls on the scent and deadens it. During a white frost, the scent lies high; as it also does when the frost is quite gone; there is a time, just as it is going off, when it never lies: it is a critical minute for hounds, in which their game is frequently lost. In heathy countries, where the game brushes as it goes along, scent seldom fails. Where the ground carries, the scent is bad for a very evident reason, which hare hunters, who pursue their game over greasy fallows, and through dirty roads, have great reason to complain of."

It has been observed that, in some particular spots, in almost every country, let the temperature of the air be what it may, that hounds can never carry a scent across them. There is little doubt, however, even in these cases, that the reason of this failure of scent might be philosophically and satisfactorily explained.

The ingenious author of *Observations on Hare Hunting*, in speaking of scent, says, the qualities of those portions of matter that discharge themselves from the bodies of beasts of game, would much better suit the experiments of a philosopher than a huntsman. Whether considered as an extraneous stock of odoriferous particles given them by Divine Wisdom for the very purpose of being hunted? Whether they are proper identical parts of the animal's body, that continually ferment and perspire from it? Whether these exhalations are from the breath of the lungs, or through the skin of the

whole body? are queries that deserve the subtilty of the virtuoso.

The author contends that the particles of scent evaporated must be inconceivably small, as he has taken many hares, after a chase of two, three, four, or five, hours, without being able to perceive the least difference in weight from those that have been killed on their forms; nor from gentlemen who have hunted box hares, could he learn, that they discovered any visible waste in their bodies, further than might be supposed to arise from the effort of discharging their grosser excrements. But, admitting the loss of two or three drachms after so long a fatigue, yet how minute must be the division of so small a quantity of matter, when (deducting the number of those particles that are lost upon the ground, dissipated in the air, and extinguished or obscured by the fetid perspirations of the dogs and other animals) it affords a share to so many couple of hounds, for eight or ten miles successively. To a sportsman, it is needless to observe (continues the author) that scent depends on the state of the weather, and is affected by its vicissitudes; a storm will, in an instant, destroy it; nor is this to be wondered at, if we consider these particles of scent are of an exactly equal specific gravity with those of the air, and which always fall and rise in just proportion to it. Huntsmen, who are hasty, rate and curse those hounds (which yesterday were the best in England) for galloping with their noses in the air as if their game was flown, when, in fact, it is in vain for them to seek the scent in any other place, the increasing weight of that fluid element having wafted it over their heads. The most terrible day for the hare is, when the air is in its mean gravity tolerably moist, but inclining to grow drier, with a mild breeze; the moderate gravity buoys up the scent as high as the dog's breast, the vesicles of moisture serve as canals to carry the effluvium into their noses, and the gentle wind so much helps to spread it, that every hound, even at eight or ten paces distance, especially with the wind, may have a due portion.

It seems strange, at first view of the case, that a hare, after a hard run of eight or ten miles should, nevertheless, continue as heavy as when she first started, although that evaporation, called scent, has been constantly issuing from her; and perhaps the only way of accounting for this seeming paradox is, by supposing that the

continual discharge, just mentioned, is supplied by the atmospheric air, something after the manner of inspiration or expiration; thus, it may be supposed that every time the hare draws her breath, the pores of her body inhale, as it were, a certain portion of the atmospheric air, which is again ejected in the form of scent.

But the author continues—That the same hare will, at divers times, emit finer or grosser particles, is equally manifest to every one observant of the frequent changes in a single chase. The coursing of a cur dog is ever the occasion of a fault; and, after such an accident, the hounds must be again and again put upon the scent before they will acknowledge it for their game: the reason is, the alteration in the motion of the chase causes one in the perspiring particles. The alterations of scent in a yielding hare, are less frequently productive of faults, because they are more gradually and insensibly growing smaller; but that alterations there are, every dog-boy knows, by the old hounds pressing forward with greater earnestness as the hare is near her end.

The coursing of a cur dog will certainly cause a difference in the scent; that is, it will make the scent much worse; but, with all due deference to the author from whom we have been quoting, we are of opinion that this difference mainly arises, not so much on account of the alteration in the motion of the chase, as from the dog following the hare, and thus sweeping away the particles of scent before the hounds reach the spot.

But to proceed:—Motion, continues the author, is the chief cause of discharging the particles of scent, because a hare is very seldom winded whilst quiet in her form, although the hounds are so near as nearly to run over her; sometimes, indeed, she is chopped upon her seat; but this, probably, is the consequence of her own curiosity, in moving and rising up in it to watch the proceedings of her enemies. It is very plain, the slower the hare moves, the stronger and grosser are the particles of scent she leaves, which is one reason that the morning walk will yield scent so much longer than in flight when hunted.

It is diverting to hear country fellows, on sight of a hare, cry out she is all over in a *sweat*; the most indifferent sportsmen know to the contrary, and that, on the nicest examination, no proof has ever been found any more than of the sweating

of a dog or a cat. Another prevailing notion is, that the longer a hare is hunted, the weaker the scent grows. But, continues the author, I never found such an alteration; and if any judgment is allowed to be formed from the action of the hounds, the old staunch dogs will be found to rate on, towards the conclusion of the chase, with additional vigour, surely not from decay of scent, but the contrary, and from which they become, every yard they go, more sensible of their near approach to the hare, than all the hunters in the field. Yet, should it be still maintained that the scent does really decrease the more a hare is pressed, what can it be owing to?—To lay it down as fact, without offering some reason, is certainly a very arbitrary determination. Is it because she is run out of wind? If that is allowed, those who insist that the hounds hunt the *foot*, must give up the argument; for, what reason can be assigned why a hare's feet, immediately preceding her death, do not leave as strong and equal a scent as at first starting from her seat?

Hares and other creatures, hard run, perform their inspiration and expiration very quick, at least in the proportion of six times to one, supposing them not urged beyond their natural pace, or to remain perfectly cool and quiet. If, therefore, *six* expirations, under severe pursuit, are equal to *one* when a hare is just started, what difference can there be in the scent?

It may be alleged, that the scent lies stronger at first, because it makes its return from a full stomach, or, that, at starting, the lungs not having suffered much distension, she breathes freer, which, by running low to the earth, intermixes better with the herbage. On the other hand, that a hare long hunted, runs high, and of course emits her breath farther off from the surface; therefore, more liable to be soon separated, and overpowered by the wind.

To the first part it is answered, the faster a hare runs the longer she stretches; therefore, the lower she lies to the ground; but the further the hounds are behind, and her breath (although expired ever so free) remains a long time, in proportion to the distance, before the dogs come up to enjoy it.

In the second place, the hard pressed hare makes her stretches shorter, which brings her body naturally more upright and high from the surface, and the scent

is hereby more likely to suffer from the wind and weather; but then, as she breathes quick in proportion, and shortens her pace in a sensible degree, the hounds, so much as she shortens, do they hasten, being urged on by an increasing scent. The only natural reason why a hare, towards the end of the chase, is often difficult to be killed, is, that she confines her works in a much shorter compass, doubles here and there, over and over, shifts, redoubles, and tries all places for rest and security, making very much foiling in a little space, which variety of *equal scent* puzzles the hounds exceedingly; and if the hounds are not thorough masters of their business, or if the air be not in due balance, the difficulty will be greater.

It is also to be remembered, that there is no small accidental difference in the very particles of scent, which are more distinguishable at one time than at another; that there is a difference in other animals of the same species, is evident, from the hounds formerly used for tracing and pursuing thieves and deer stealers, and likewise from any common cur or spaniel, who will hunt out his master or his master's horse, distinctly, from all others; and that it is the same with the hare is no less visible from the *old* beagles, which will not readily change for a fresh one, unless she start in view, or unless a long fault happen, which puts them in confusion, and inclines them in despair to take up with the next scent that presents itself.

Of the influence which frost has upon scent, the author observes, that he has often been disappointed in the hounds hunting the trail of a hare up to her seat, and frequently been able to hunt her walk in one part of a field, and not in another; that at ten or eleven o'clock, the same walk which gave the least scent at seven in the morning, has afforded the best; but what has been more perplexing, the hounds have only been able to hunt it at the wrong end, or backwards, and after many hours' expectation; the fact is, that hounds are never so far from their game as when they hunt it the warmest. All these accidents are only the effect of the *hoar frost*, or very gross dew (for they never happen otherwise) and from thence must the miracle be accounted for. At the going off of a frost, the mercury is commonly falling, and by consequence the scent sinking into the ground. The earth is naturally, on such occasions, fermenting, stinking, and very porous; so that it

is impossible but that most of the particles of scent must be corrupted, buried, or destroyed by stronger vapours: it is common to hear it said, the hare carries dirt in her heels; but that is not all, for by what has been alleged it is plain she is not so eagerly pursued by the scent of her feet only. Thus, having ascertained that a *thaw* tends to corrupt the particles of scent, it leaves a fair reason to maintain that the *frost* fixes, covers, and preserves them. Whether this is done by intercepting their ascent, and precipitating them to the ground by the gross particles of frozen dew, or whether by protecting them from the penetrating air, is not professed to be decided; but the facts are certain, confirmed by experience. We have therefore only to take notice that the hoar frost is very often of short continuance, changeable and uncertain, both as to its time and place of falling; and hence all those difficulties are easily resolved. Let the huntsman, as soon as he is out of bed examine the glass in the windows, which commonly discovers whether any hoar frost has fallen, what time it came, and in what condition of continuance or going off it is for the present. If it appears to have fallen at two, three, or four in the morning, (suppose in the month of October, and other times of the year must be judged of by proportion,) and to be going off about day break, it may then be expected that there will be a great difficulty or impossibility of trailing to her seat; because, her morning retreat being on the top of the frozen dew, the scent is either dissolved or corrupted with it, or dissipated and exhaled. It is true, after such a night, the dogs will find work in every field, and often hunt in full cry, but it will be generally backward, and always in vain, her midnight ramblings (which were covered by the frost) being now open, fresh, and fragrant. If the said frost begins later in the morning, after Puss is seated, there is nothing to be done till that is gone off.

Finally, it is evident that the state of the atmosphere is the principal consideration of the sportsman in regard to scent. This subtle fluid, it is well known, is always wafted by the wind, and at times to very considerable distances. Thus the vulture is directed to carrion even for the distance of a league; and amongst quadrupeds, we see a similar circumstance obtain: in the season of love, the male is thus directed to the female; and hence the dog, the bull, the stallion apply their nostrils to the ambient air, and proceed accordingly.

**SCIATICA** or **RHEUMATISM** IN HORSES. See the article **RHEUMATISM**.

**SCIRRHOUS**. An induration of the glands, such as happens to the liver in many animals. It is reckoned one of the terminations of inflammation. Gibson defines it, a very hard swelling, sometimes entire, smooth, and without pain; sometimes divided into little knots and bundles, seated for the most part among the glands and kernels.

**SCOURING** or **LOOSENESS**. This complaint is properly an increased action of the peristaltic motion of the intestines, with a greater secretion of a watery fluid within the intestines; or, otherwise, a want of a proper absorption of the fluid part of the intestinal contents; whereby there follows a frequent evacuation of the dung in a very liquid form. It is distinguished from dysentery by the purging being complete from the very first; by its being more copious, having all the *fæces* in solution without a glairy mucous matter, erroneously considered as the fat of the body; and, also, by being seldom accompanied with fever, or any great affection of the general health, unless it be long continued. Some horses are very liable to purging on every exertion, and such are termed, by grooms, washy, having usually narrow chests and lank bellies, by which the intestines have not sufficient room for their natural processes, but are pressed on, and thus forced to a hasty expulsion of the unassimilated contents.

Diarrhoea may arise from mechanical pressure, resulting from the form; or from a constitutional debility in the intestines themselves, dependant on the causes above-mentioned. A weakened state of the bowels, inclining to this affection, is often brought on by drastic purges likewise. These may be all considered as constitutional causes, and such as are liable to a frequent recurrence; but beside these, there arises a more active and serious affection, dependant on some morbid change taking place in the secretions of the stomach and bowels, whereby those secretions become a source of irritation to the organs themselves. The bile very commonly takes on such a change, and there is reason to believe that this is a fruitful source of diarrhoea. The food itself likewise becomes, at times, improperly assimilated, and enters into new combinations with the gastric juice, whereby an acrid matter is formed: this matter has been supposed to be an acid, and hence absorbent earths have been much used in this complaint.

Horses moving from hay to grass, or even from grass to hay, become affected with looseness; for the stomach and bowels prove unequal to the office of assimilating a new food at once, and hence they are irritated to an early expulsion of their contents, as a matter foreign and incapable of perfect assimilation.

Diarrhœa may be symptomatic, or the effect of some other complaint, in which case it ought not to be too hastily checked. It is frequently occasioned by the sudden application of cold, whereby the exhalent arteries of the skin becoming checked, more fluid is necessarily thrown on the intestines: and which operates not only by increasing their quantity, but likewise by the addition of something foreign, and hence irritating, to them. In such case, the restoration of the healthy action of the skin is necessary to a cure; and as the balance of power has been in favour of the intestines, it would be desirable now to turn it in favour of the skin, by making use of the few sudorifics we know of, as *sp. Mind.*, warm clothing, &c. &c.; and by avoiding the use of active astringents. It may, however, be remarked, that horses are not much subject to symptomatic purging, or looseness; and therefore there is less danger of checking such affections in them than in the human subject.

It is seldom dangerous, unless very violent, or long continued; or unless, by improper treatment, it should inflame the inner surface of the intestines, and thereby degenerate into dysentery or enteritis.

*The Treatment.* It is so very seldom, as before observed, that this complaint is critical or purely symptomatic, that it but rarely requires aperients to commence the cure with; therefore mild astringents, in general, may be at once proceeded on. The longer the complaint continues, the farther it proceeds along the alimentary track, so that, at the last, the cœcum and rectum become equally affected, and then a distressing tenesmus prevails. This circumstance is not sufficiently attended to in the cure of diarrhœa; for in these cases it will be often in vain to give astringents by the mouth, which become so changed in the long alimentary track, as to reach these latter bowels almost inert; but in such instances, astringent injections will frequently effect all we wish. Commence, however, the cure of the general cases of diarrhœa by giving the following drink once or twice a-day, according to the violence of the complaint:—

Prepared opium, half a dram;

Powdered catechu, two drams;  
Prepared chalk, two ounces;  
Starch, boiled thin, a pint.

Mix.

In very obstinate looseness, half a dram of alum may be added, and the quantity of opium doubled; and in such case, and also whenever the affection has been long continued, once or twice a-day give the following clyster:—

Boil six poppy heads in four quarts of water to two, add to the liquor

Prepared chalk, two ounces;  
Boiled starch, two quarts.

Mix.

To this also, if necessary, alum may be added; and should the horse be weak, boiled starch, or arrow root, or boiled bean meal, may be horned down the throat frequently; give no cold water to drink, but, instead, give thin gruel or rice water, chilled. Clothe warmly, encourage a warm temperature also, and carefully avoid exposure to sudden currents of cold air. To the more intimately understanding of this complaint, under its several varieties, see the subject of Dysentery.

For the cure of diarrhœa, when brought on by superpurgation, Mr. Bracey Clark recommends

Sulphat of soda (Glauber's salt) two ounces;

Sulphat of magnesia (Epsom salt) one ounce;

Muriat of soda (common salt) ten grains;

Sulphat of iron (green vitriol) two grains.

Mix in warm water and give, repeating it if necessary.—*Blaine.*

**SCRATCHES.** A distemper in horses, of several kinds, distinguished by various names, viz. crepances, rat-tails, mules, kibes, pains, &c. being no other than the scratches, which are certain dry scabs, chops, or rifts, that occur between the heel and pastern joints, and do many times go above the pastern, to the very hoof of the hinder-legs, and sometimes are upon all four legs, though this is not very common. Scratches in the heels have so much affinity with the grease, and are so often concomitants of that distemper, that the method of treating them may be selected chiefly from what has been said under the article grease.

**SCUT.** The tail of a hare or rabbit.

**SEAMS.** A term formerly in use to signify the re-union of divided parts in the hoof of a horse, as a cured sandcrack; or the cleft at the junction of a false

quarter, with the uninjured part of the foot.

**SEA FISHING.** There are four ways of sea fishing in use, in some parts of Scotland, and which are worthy of notice from their peculiarity.

First, with leesters, a kind of four-pronged fork, with the prongs turned rather to one side, having a shaft twenty or twenty-five feet long. These they run along the sand on their edge, or throw them when they see any fish, and in this manner destroy great quantities. Some are very dexterous, and will, upon horse-back, throw a leester, and kill at a long distance. This is also called shawling, being usually practised when the tide is nearly expended, and the waters get shallow.

The second mode, termed heaving or hauling, is by standing in the stream, either at the flowing or ebbing of the tide, with a net fixed to a frame, consisting of a beam twelve or fourteen feet long, having three small sticks or rings, fixed into it in the middle, and one at each end; to these the net is fixed by a small line. This frame is opposed to the current, so that whenever a fish strikes against the net, they, by means of the middle ring, haul up the mouth of the net above the surface; and the fish which was caught in the bag of the net, is killed with an instrument kept for that purpose. A dozen or twenty men, will sometimes stand abreast, in strong running water, for three or four hours together. Such a company is called a *mell*.

Thirdly, pock-net fishing. This is performed by fixing stakes in the sand, in such places as become dry at low water. These stakes are driven forty inches separate, across the tide way, and about three feet high; between every two of these stakes, is placed a sack of net-work (called a *pock-net*), and tied by a rope to its top, and the bottom secured by a hook or ring of twisted willow, slipt on to the stake, where it is moveable; the meshes of these nets, which are about three feet wide both ways, are large, so that the fish, moving rapidly with the stream, run their heads into these meshes, and are unable to disengage themselves: when the tide is spent, the fish are taken out. Five of these pocks are termed a clout, and ten clouts are the extent allowed to each fisherman, who has only one share in the fishery. The distances are also regulated, so that the nets of one must not be set within a certain limit allowed to another.

Fourthly, ralse-net fishing. This is by far the most profitable, yielding a considerable rent. The name is derived from the lower part of the net, rising and floating upon the water with the flowing tide, and setting down with the ebb. This has likewise the appellation of lake fishing, from the nets being always placed in lakes, or hollow parts of the tide-way, and never, either in the channel, or on the plain sand. The staves are mostly twelve feet long, driven deep into the sand, and in a row across a lake or hollow, at six feet distance, a strong rope is passed along, and fastened to the head of each, to this is joined a net, about ten feet deep, tied also at the bottom with a rope, but not fastened below to the staves, the lower part of course floats, as the tide rises, but when it begins to turn, the net is pushed to the bottom by the returning stream, and which prevents any fish getting down the channel, when the tide is spent. The fisherman or owner comes, every twelve hours, to see what are caught. If the hollow does not ebb quite dry, they use a drag net, to sweep out the fish, and large quantities of salmon, sea trout, herrings, cod, flounders, and sometimes sturgeons, are thus taken.

**SEA FOWL, MODE OF TAKING.** In St. Kilda, the fowling parties generally consist of four persons of agility and skill. Each party must have at least one rope, about thirty fathoms long, made of a strong raw cow-hide, salted for the purpose, and cut circularly into three thongs of equal length; these thongs being closely twisted together, form a threefold cord, able to sustain a vast weight, and durable enough to last two generations; to prevent its receiving injury from the sharp edges of the rocks, it is covered with sheep-skins dressed in the same manner.

This rope is the most valuable piece of furniture a St. Kilda man can be possessed of; it makes the first article in the testament of a father; and if it fall to a daughter's share she is esteemed one of the best matches in the island.

By the help of these ropes, linked together in couples, each having the end of the cord fastened about his waist, they go down and ascend the most dreadful precipices. Mr. Macauley gives an instance of the dexterity of the inhabitants of St. Kilda, in their fowling, to which he was an eye-witness. One of them fixed himself on a craggy shelf, his companion descended about sixty feet below, and

having darted himself away from the face of a most frightful rock hanging over the ocean, began to play his gambols ; he sung merrily, and laughed very heartily ; at last, having afforded all the entertainment he could, he returned in triumph, full of his own merit, with a large string of birds about his neck, and a number of eggs in his bosom.

In the Isle of Egg, there are two incidents relating to the pullin. The one, that though sea fowl, they here lay and hatch, sometimes at a great distance from the shore, and near the tops of high hills. Their young, before they leave the nests, are as large as the dam, transparent with fat, and delicious to the taste of many. It is believed that the young puffins become so weighty with fat as to be incapable of taking wing, or quitting the nest : to remedy this, the old puffin is said to administer sorrel to extenuate, and render it fit for flying. At any rate, it is a known fact, that sorrel is, in this island, commonly found to grow near the puffin's nest.

**SEAT.** The position on horseback. A person once mounted, and sitting at his ease, free from every seeming constraint, with his body plially erect, his thighs and knees adhering closely to the skirts of the saddle, an easy freedom in his legs, and a personal motion corresponding with the action of the horse, is said to have a good seat. Those who are always changing their position, throwing about their arms, swinging their legs, looking every way but the right, with stirrups too long, too short, or probably one shorter than the other, are horsemen of a very different description, having a very bad seat, or rather no seat at all.

**SEELING.** A horse is said to seel, when, upon his eye-brows, there grow white hairs, mixed with those of his usual colour, about the breadth of a farthing, which is a sure mark of old age. A horse never seels till he is fourteen years old, and always before he is fifteen, or sixteen at farthest : the light sorrel and black seel sooner than others.

**SEPTEMBER.** The partridge shooting season commences on the first of this month. The courser also pursues the hare. Harriers go out at an early period of the morning. Fox-hounds commence cub hunting.

**SETON.** A cord or number of threads laid together, and drawn through the skin by the help of a needle of a proper shape. Mr. Clark gives the following in-

structions on the application and use of setons in the diseases of horses.

"Setons (says he) are of great use in carrying off matter from deep-seated abscesses in different parts of the body. They ought at all times to be used in preference to making deep incisions into the muscular parts ; for these not only disfigure horses, but are afterwards very difficult to heal up, on account of the unfavourable situation of some of those tumours, and the horizontal position of the body, which in many cases will not allow of a depending opening to carry off the matter, as in tumours on the back, withers, and the upper part of the neck, immediately behind the ears, which are very common. Nor is the horizontal position of the body the only impediment ; for the natural restlessness and impatience of a horse, renders it impracticable to fix proper bandages on these elevated parts ; nor will the situation of them admit of proper dressings being fixed so as to remain for any length of time. Hence the openings made into such tumours are frequently left bare, and exposed to the cold air, &c. degenerate into very foul ulcers, and produce a very great deal of fungous flesh, which requires to be repeatedly cut away with the knife, as the strongest caustics that can be applied are not sufficient to retard its growth.

Setons are introduced by long, thin, flat, sharp-pointed needles, shaped like a dart at the point, and having, at the other extremity, an eye to receive the cord, which is to be left in the tumour. The size of the instrument may be determined by that of the tumour, and the thickness of the cord which is to follow it, and which at all times ought to be smaller than the perforation made by the point of the needle. Every veterinary surgeon should be possessed of a number of these needles of different sizes, that is, from six to fourteen or fifteen inches long, a little bended on the flat or under side."

Mr. Clark describes the following as the readiest method of applying setons in different cases.

"When matter is found to fluctuate in the tumour, the needle, armed with a cord at the other end, is to be introduced at the upper part of it, and the sharp point of the instrument directed to, and brought out at, the under or lowermost part of the tumour, including the whole length of it ; or, if needful, through the sound muscular flesh on the under part, in order to procure a depending orifice

for the matter to run freely off. The cord should be dipped in some digestive ointment, and then tied together at both ends with a thread, in order to prevent its slipping out; but if, from the length of the perforation, the cord should not admit of being tied together at the ends, a small button of wood, or some such substance, may be fixed at each end; only, from this circumstance, the cord will require, when shifted occasionally, to be drawn upwards and downwards; whereas, when the ends of it are tied together, it forms a circle, and may always be shifted downwards to the lower orifice; when the matter in the tumour appears to be wholly discharged, or dried up, and no thickness appearing but where the cord is, it may then be drawn out, and the orifices suffered to heal up.

When the needle for introducing the seton is to pass near to any large blood-vessels, or nerves, in order to prevent the chance of their being wounded, it may be concealed in a canula, open at both ends: and after an opening is made at the upper part of the tumour, sufficient to admit the needle, with its canula, it may then be directed, with safety, past the blood-vessels, &c. We may then push the needle forward through the canula to the opposite side of the tumour, and having only the common teguments to perforate, all danger will be at an end."

The importance of the seton in treating abscesses on the withers, &c. is shewn by Mr. Clark in the following way: "The common method (says he) of treating those large tumours which are seated on the upper part of the neck, immediately behind the ears, generally known by the name of the poll-evil, and also those which are seated on the withers, or upper parts of the shoulders, is exceedingly improper. They are either allowed to break of themselves, or are opened the whole length of the tumour on the upper part; in which situation, especially in the poll-evil, when the head is always kept in an erect position, the matter contained in the tumour cannot be discharged from it, but is retained in the bottom of the wound, and exposed to the external air, &c. Here it soon acquires a most corroding quality, and produces a large and sordid fistulous ulcer; a great quantity of fungous flesh is also produced, and this requires to be repeatedly extirpated with the knife, or other means; and hence the horse is greatly disfigured, the cure becomes both tedious and uncertain, and is seldom rad-

ical. In some cases, I have known the vertebræ of the neck affected by the sharpness of the confined matter, forming lodgments there, and, after great trouble and expence, the horses were obliged to be put to death at last."

Mr. Clark, no doubt with great truth, avers, that these tumours are easily and speedily cured by the use of setons, as above described; and that without any loss of substance, or even disfiguring of the parts. "Of a number of cases (says he) where this operation has succeeded with great expedition in curing these tumours, I shall only mention the following:—

About eight years ago, an Arabian horse, belonging to a gentleman in this place, had a large tumour seated a little on one side of the withers, or upper part of the shoulder; it was forwarded by applying emollient poultices; and, as soon as the matter was perceived to fluctuate in the tumour, a large seton needle, armed with a cord at the other end (as described above), was introduced at the upper part of the swelling, and brought out at the under or lowermost part of it; the matter was discharged at the lower orifice in a very short time, the tumour was by that means soon discussed, and in a few weeks it was entirely healed up, without any scar or blemish remaining, farther than a little baldness about the lower orifice, occasioned by the sharpness of the matter; but this likewise soon disappeared, and not the least trace of the disorder remained."

Another case is described by Mr. Clark as follows:—"A coach horse (belonging to a nobleman in the neighbourhood) had a large tumour a little behind the ears, on the neck, which, as formerly observed, is called the poll-evil; the tumour extended to both sides of the neck, and was divided in the middle by the mane; the tumour had been opened on one side, in a very superficial manner, by a farrier in the country, before the matter in it was sufficiently digested: after applying a few emollient poultices, in order to ripen it, a strong seton needle, as already described, was introduced at the upper part of it, almost close to the mane, and, after passing it through the bottom of the tumour, which was very deep, the needle was brought out through the sound muscular parts below the tumour, in order to procure a depending orifice for the matter to run freely off. The same operation was likewise performed on the opposite side,

*very dry season*, exposes this animal to great inconvenience; not that the smooth pointer is by any means exempt from that excessive thirst, which is uniformly produced by great exertion under a burning sun; but, as he is more thinly clad, and generally moves slower, so is he, consequently, less in want of water. But, after all, it does not often happen, that water is so very scarce on the moors; on the contrary, those who visit the grouse mountains, may generally calculate on walking with wet feet; and the weather must be much more than ordinarily dry, when the dogs suffer much inconvenience from thirst.

Another supposition which generally obtains belief, respecting the comparative merits of these two animals, is neither so reasonably nor so justly founded, namely, that the olfactory organs of the setter are inferior to those of his foreign rival. On this subject, it seems necessary, in the first place, to observe, that the *best nosed* pointers are those which still retain much of the blood of the old English talbot or blood-hound (as no doubt, we think, can exist, that the Spanish pointer, when first brought to this country, was crossed with the talbot, or something, at least, approaching the talbot); and almost all those pointers of the present day, which have the best noses, are found to approximate, in form and appearance, the old English blood-hound, whose olfactory organs were, no doubt, superior to those of any other race of dogs which was ever known in these islands. The old English setter, which many years ago existed perhaps in the greatest possible perfection, has since undergone various crosses, which have not only injured the beauty of his appearance, but diminished that exquisite sense of smell, which is so essential to the delightful recreation of shooting. Dogs, *called setters*, are now to be met with of all forms, miserably deficient in the most prominent quality, *setting*, and generally very inferior to the modern pointer in every respect. Not one in a hundred of these mongrels is worth the notice of the sportsman; many of them, it is utterly impossible to *break* or train, and even of those which are in some measure forced into subordination, very few become sufficiently steady to be fully depended on, or to render their services satisfactory. It is true, sometimes one is met with of approved worth, but instances of this sort are not very numerous.

A narrow headed setter, like a narrow headed hound, can never possess an exquisite sense of smell.

We are told that the sportsmen of Ireland are more partial to setters than pointers; and, for aught we know to the contrary, they may be better calculated for that country. A similar notion prevails in the Highlands of Scotland (which afford the best shooting in the world); and few pointers are to be met with in these parts, at least in the hands of the natives. What we saw in an excursion through this mountainous country in August, 1824, were ill bred worthless animals, though we are fully convinced from experience, that a well-bred pointer is as superior to the setter in the Highlands of Scotland, as in the inclosures, or upon the grouse mountains of England; nor have we the least doubt, that if a good breed of pointers were intro-

## S E T T E R

duced into the sister kingdom, that the Irish sportsmen would prefer it to their favourite setter. We have seen several Irish setters (chiefly red) which were certainly good dogs.

It is but of late years that the pointer has attained that degree of excellence, which raises him above his long coated competitor. In the time of Somerville, pointers were but little regarded, as he has not even noticed them; but he has the following beautiful apostrophe to the setter:—

When autumn smiles, all beauteous in decay,  
And paints each chequer'd grove with various hues,  
My setter ranges in the new shorn fields,  
His nose in air erect; from ridge to ridge,  
Panting, he bounds, his quarter'd ground divides  
In equal intervals, nor careless leaves  
One inch untry'd. At length the tainted gales  
His nostrils wide inhale; quick joy elates  
His beating heart, which, aw'd by discipline  
Severe, he dares not own, but cautious creeps,  
Low-cowering, step by step, at last attains  
His proper distance; there he stops at once,  
And points with his instructive nose upon  
The trembling prey. On wings of wind upborne,  
The floating net unfolded lies; then drops,  
And the poor fluttering captives rise in vain.

It is hastily supposed by some, that the dog now under consideration, is naturally disposed to crouch or drop on his belly when setting or pointing his game; but this is merely the effect of education: the pointer may be taught to crouch as well, if not better, than the setter; and, on the contrary, the setter may be taught to *stand* precisely in the same manner as the pointer. This mistaken notion has been propagated by the consummate ignorance of those who have assumed a knowledge of the subject, and given their wretchedly contemptible excogitations to the world through the medium of the press. Thus, in the Sportsman's Cabinet, we find the following ridiculous nonsense:

“Although the setting dog is in general used merely for the purpose of taking partridges with the draw net, yet they are sometimes brought into occasional use with the gun, and are equally applicable with that appropriation; except in turnips, French wheat, standing clover, ling, furze, or other cover, where their sudden drop or point may not be so readily observed.”

Daniel, in the Rural Sports, is equally eloquent, and equally ignorant, on the subject; and as a sort of climax to his own stupidity, after admitting that he was never on the grouse mountains, gives the portrait of his favourite setter *Beau* “*pointing the black cock!*”

The setter is capable of enduring much fatigue, a striking instance of which occurred with one of these animals, the property of the late celebrated Mr. Elwes; which followed its master to London, a distance of sixty miles, hunting the fields adjoining the road all the way as they passed along.

The late Dr. Hugh Smith related the following tale of a setter:—

As the Doctor was travelling from Midhurst into Hampshire, the dogs, as usual in country places, ran out barking as he was passing through the village, and amongst them he observed a little ugly cur that was particularly eager to ingratiate himself with a setter bitch that accompanied the Doctor: whilst stopping to water his horse, he remarked how amorous the cur continued, and how courteous the setter seemed to her admirer.—Provoked to see a creature of Dido's high blood so obsequious to such mean addresses, the Doctor drew one of his pistols and shot the cur; he then had the bitch carried on horseback for several miles. From that day, however, she lost her appetite, ate little or nothing, had no inclination to go abroad with her master, or attend to his call; but seemed to pine like a creature in love, and express sensible concern for the loss of her gallant. Partridge season came, but Dido had no nose. Some time after she was put to a setter of great excellence, which had, with great difficulty, been procured for the purpose; yet not a puppy did Dido bring forth, but what was the picture and colour of the cur that the Doctor had, many months before, destroyed; and in many subsequent litters Dido never produced a whelp that was not exactly similar to the unfortunate cur already mentioned.

**SETTER.** In the game of hazard, is the person who sets the caster; or, in other words, the player, who makes stakes with the person holding the box and dice, who, if he throws in, draws the money; on the contrary, if he throws out, the setter is the winner.

**SETTER-TO.** A term in cocking. The setter-to is the person who receives the cock (going to fight) from the feeder, and hands him upon the sod during the battle, according to the laws of the pit, and the conditions of the match. See **COCKING.**

**SHAD.** Pennant says the shad arrives in the Thames the latter end of May, or early in June, and is a very coarse fish; it sometimes grows to the weight of eight pounds, but the usual size is from four to five. This is the fish which Du Hamel describes as the true *alose* of the French; but the Thames fishermen have another they call *allis*, much less than the former, with a row of spots from the gills along the sides, just beneath the back, more or less in number: this the French call *le feinte*. I suspect, says Mr. P. that the name *allis* is misapplied to this species, and that it ought to be applied to the greater common shad, being an evident corruption from the French name *alose*: is the same with that of the Severn, but is rarely taken here; but neither of them is admitted to good tables.

In Great Britain the Severn affords this fish in higher perfection than any other river. It first appears there in May, but in very warm seasons in April; for its arrival, sooner or latter, depends much on the temper of the air. It continues in the river about two months.

The Severn shad is esteemed a very delicate fish about the time of its first appearance, especially in that part of the river that flows by Gloucester, where they are taken in nets, and usually sell dearer than salmon: some are sent to London, where the fishmongers distinguish them from those of the Thames by the French name of *alose*. Whether shads spawn in the Severn and the Wye is not determined,

for their fry has not yet been ascertained. The old fish come from the sea into the river in full roe. During the months of July and August, multitudes of bleak frequent the river near Gloucester; some of them as big as a small herring, and these the fishermen erroneously suspect to be the fry of the shad. Numbers of these are taken near Gloucester in those months only, but none of the emaciated shad are ever caught in their return.

The shad of the Thames does not frequent that river till the latter end of May or beginning of June, and is deemed a very insipid coarse fish. The Severn shad is sometimes, though rarely, caught in the Thames, and called *allis* (no doubt *alose*, the French name) by the fishermen in that river. About the same time, and rather earlier, the variety, called near Gloucester the *twaite*, makes its appearance, and is taken in great numbers in the Severn, and is held in as great disrepute as the shad of the Thames.

The differences between each variety are as follows:

The true shad weighs sometimes eight pounds, but their general size is from four to five.

The twaite on the contrary weighs from half a pound to two pounds, which it never exceeds.

The twaite differs from a small shad only in having one or more round black spots on the sides; if only one, it is always near the gills, but commonly there are three or four, placed one under the other.

The other particulars agree in each so exactly, that the same description will serve for both. The head slopes down considerably from the back, which at the beginning is very convex, and rather sharp: the body from thence grows gradually less to the tail. The under jaw is rather longer than the upper; the teeth very minute. The dorsal fin is placed very near the centre, is small, and the middle rays are the longest: the pectoral and ventral fins are small; the tail vastly forked: the belly extremely sharp, and most strongly serrated. The back is of a dusky blue; above the gills begins a line of dark spots, which mark the upper part of the back on each side; the number of these spots is uncertain in different fish, from four to ten.

In the Elements of Natural History, this fish is described in the following manner:—In May and June the shad ascends the rivers, and deposits its spawn in rapid streams. In autumn it returns. It is from two to three feet long, lives on worms and insects; it is preyed upon by the siluri, pikes, and perches. It is detested by the Russians and the inhabitants of the Wolga, although it is much relished elsewhere, and in India its ova are as highly esteemed, as caviar is by the Russians. It is covered with large scales which easily come off.

**SHANK OF A HORSE.** That part of the fore-leg which is between the knee and the fetlock or pastern joint. The larger and broader the shank is the better. It is known to be so, by the back sinew being at a distance from the bone, or well separated from it, and having no kind of swelling betwixt it and the bone, which may cause the leg to appear round.

**SHARK.** A brown horse, foaled in 1771, bred by, and the property of, Charles Pigott, Esq. Shark was got by Marsk; his dam by Snap; grandam, (Warwickshire Wag's dam) by Marlborough, out of a natural barb mare.—Shark was his dam's first produce.

At Newmarket first October meeting, 1774, Shark, 8st. beat Mr. Greville's Post-

master, same age, 8st. 8lb. Ditch-in, 500gs:—5 to 4 on Postmaster. On Monday, in the second October meeting, he received forfeit from Mr. Blake's Prior, 8st. 7lb. each, Ditch-in, 200gs. h. ft. And on Tuesday, at 8st. 2lb. he beat the Duke of Ancaster's Jacinth, 8st. Ditch-in, 300gs.—3 to 1 on Shark.

At Newmarket first spring meeting, 1775, Shark won a sweepstakes of 200gs. each, h. ft. (10 subscribers) for colts, 8st. fillies, 7st. 11lb.; Ditch-in, beating Lord Grosvenor's Laurel, Lord Grosvenor's Glimpse, and Lord Bolingbroke's colt, by Syphon, dam by young Snip:—6 to 4 on Laurel, and 2 to 1 against Shark. On Saturday, he won a sweepstakes of 100gs. each, and a hogshead of claret each, (the owner of the second was entitled to two hogsheads); colts, 8st. 7lb.; fillies, 8st. 4lb.; B. C. beating Lord Grosvenor's Laurel, Mr. Brand's Mayfly, Mr. Blake's St. George, and Mr. O'Kelly's Juno, by Marsk:—Mr. Greville's Postmaster, Mr. Vernon's Plunder; and six others paid. On Monday, in the second spring meeting, he received forfeit from Mr. Douglas's Lady Squander, 8st. each, Ditch-in, 300gs. h. ft. On Tuesday, he walked over B. C. for the Clermont cup, value 120gs. and 100gs.; (2 subscribers). On Friday, he walked over B. C. for a subscription of 25gs. each, (13 subscribers) for four-year olds, 8st. 7lb. And on Monday after the meeting, he beat Lord Rockingham's Cincinnatus, aged, 8st. 7lb. each, across the flat, 500gs:—5 to 2 on Shark. At Newmarket, September 25, he beat Lord Clermont's Johnny, 6 years old, 8st. 7lb. each, B. C. 1000gs:—6 to 5 on Shark; Johnny fell in coming up the Ditch-hill.

At Newmarket first spring meeting, 1776, Shark beat Mr. Greville's Postmaster, 8st. each, R. M. 1000gs:—2 to 1 on Shark. On Monday, in the second spring meeting, at 8st. 7lb.; he won a sweepstakes of 1000gs. each, B. C. beating Lord Grosvenor's Laurel, 8st.; and Mr. Greville's Postmaster, 8st.—6 to 5 against Shark, and 5 to 4 against Laurel. On Wednesday, at 8st. 13lb. he beat Lord Rockingham's Rake, aged, 8st. 3lb. across the flat, 1000gs:—5 to 2 on Shark. On Saturday after the meeting, he beat Lord Abingdon's Leviathan, 10st. each, B. C. 500gs:—5 to 4 on Shark. In the July meeting, at 8st. 7lb. he received forfeit from Lord Abingdon's Critic, 8st. 2lb.; B. C. 1000gs. h. ft. On Monday, in the first October meeting, he received forfeit

from Lord Clermont's Johnny, aged, 8st. each, across the flat, 500gs. h. ft. On Friday, at 8st. 7lb. he beat Lord Clermont's Fireaway, 6 years old, 7st. 4½lb.; R. M. 300gs:—7 to 4 on Fireaway. In the second October meeting, he walked over B. C. for the 140gs. for six-years olds and aged horses, 8st. 7lb. all others, 8st.

At Newmarket first spring meeting, (Monday) Shark received forfeit from Lord Abingdon's Leviathan, 9st. each, B. C. 500gs. On Saturday, at 8st. 7lb. he beat the same Leviathan, 8st. B. C. 1000gs:—5 to 2 on Shark. In the July meeting, Shark, 8st. 7lb. beat Sir C. Bunbury's Hephestion, 7st. 11lb.; Ditch-in, 500gs.:—7 to 4 on Shark. On Thursday, he won the subscription plate of 92gs. for four-year olds, 7st. 13lb.; five-year olds, 8st. 9lb.; six-year olds, 9st.; and aged, 9st. 2lb.; Ditch-in; beating Mr. Compton's Waser, aged; Lord Clermont's Masquerade, 6 years old; the Duke of Grafton's Magnet, aged; Lord Ossory's Planet, 5 years old; and five others:—5 to 2 on Shark, and 4 to 1 against Masquerade. In the first October meeting, he received 100gs. compromise from Lord Grosvenor's Mambrino, aged, 10st. each, B. C. for the Whip and 200gs. each.—Lord Grosvenor kept the whip.

At Newmarket first spring meeting, 1778, Shark, 8st. 7lb. beat Mr. Dawes' Nutcracker, 3 years old, 7st. R. M. 200gs. 7 to 4 on Shark. And in the second spring meeting, he won the Whip and 200gs. each, 10st. B. C. beating Lord Ossory's Dorimant, 6 years old:—Lord Abingdon's Pretender, aged, paid.

Shark had 36 engagements; he started 29 times, out of which he won 19:—He received six forfeits, and paid four forfeits and a compromise.—He was beat as follows: in the first spring meeting, 1774, at 6st. 12lb. (the first time of his running) by Florizel, 5 years old, 9st. 7lb.; Ditch-in, 300gs; in the first October meeting, 1775, by Pretender, 8st. 7lb. each, B. C. 500gs.; May 6, 1776, at 8st. 7lb. by Masquerade, 7st. 13lb. R. M. 500gs; in the July Meeting, at 8st. 9lb. by Dorimant, 4 years old, 7st. 13lb. for the subscription plate of 89gs. Ditch-in; in the first October meeting, by Masquerade, 8st. 7lb. each, the first half of R. M. 200gs; on Monday, after the second spring meeting, 1777, at 8st. 7lb. by Lord March's Kouli Khan, 5 years old, a feather across the flat, 300gs.; in the first October meeting, (Monday) at 8st. 7lb. by Pretender, 7st. 11lb. B. C. 1000gs; on Wednes-

day, in the same meeting, at 8st. 12lb. by Ratcatcher, 4 years old, 7st. 7lb.; and Mistle, 4 years old, 7st. 7lb. for the 140gs. B. C.; in the second October Meeting, at 8st. 7lb. by Dorimant, 5 years old, 8st. for the 140gs. B. C.; and on Monday, May 25, 1778, at 8st. 7lb. by Dictator, 5 years old, 7st. 10lb. B. C. 500gs. which was the last time of his running:—forfeits, in the second October Meeting, 1775, in a sweepstakes of 100gs. each, (5 subscribers) 8st. 7lb. Ditch-in, walked over for by Critic; in the same meeting, at 8st. 7lb. to Johnny, 6 years old, 8st. 2lb. R. M. 300gs.; in the second October meeting, 1777, at 8st. 7lb. to Leviathan, 7st. 7lb. B. C. 200gs.; and June 8, 1778, at 8st. 7lb. paid 80gs. compromise to Dictator, 8st. 1lb. across the flat, 300gs. h. ft. which was his last engagement, except his being named for the Oxford cup, won by Dorimont in 1778. He never raced but at Newmarket.

Shark won, besides the Clermont cup, value 120gs, eleven hogsheads of claret, and the whip; the sum of 16,057 guineas, in plates, sweepstakes, matches, and forfeits, which was more money than any horse ever won before.—he lost and paid 3990 guineas:—Total of winning, including the value of the Clermont cup, 12,187 guineas.

Shark was a stallion in 1779, at Cherterton-hall, near Stilton, Huntingdonshire, at 25gs. and 10s. 6d.; in 1780, at Alwalton-lodge, near Stilton, at 20gs. and 10s. 6d.; in 1781, at the same place, at 10gs. and 10s. 6d.; in 1782, at Mr. Blake's, at Beddington, near Croyden, Surrey, at 10gs. and 10s. 6d.; in 1783, at the same place, at 15gs. and 10s. 6d.; and in 1784, at 10gs and 10s. 6d.; in 1785, at Mr. Glenton's, Boroughbridge, Yorkshire, at 10gs. and 10s. 6d.; and afterwards at 5gs. and 5s. He was sire of the Duke of Devonshire's Adder, Asp, and Despair; of Mr. Blake's Andromeda, Mr. Panton's Expectation and Wasp, Lord Foley's Alligator, Mr. Hutchinson's Pitch, Mr. Eccles's Peggy Flirt, Mr. Coates's Sir John Falstaff, Mr. Haynes's Isabella, Mr. Savage's (of Ireland) Amphibious, Lord Courtenay's Daisycutter, and Sir Thomas Gascoigne's Violet, that bred Goldenlocks, Groaner, Symmetry, Slapbang, Lenox, Tooee, Theophania, &c.

Shark was about 16 hands high.

**SHEDDING OF THE HAIR.**—See **MOULTING**, page 552.

**SHELL-TOOTHED.** An epithet applied to a horse that, from five years to old age, naturally, and without any artifice, bears the mark in all his fore-teeth; inso-

much, that, at twelve or fifteen, he appears with the mark of a horse that is not yet six. For in the nippers of other horses the mark disappears towards the sixth year, in consequence of the wearing of the tooth. About the same age it is half worn out in the middling teeth, and towards the eighth year it disappears in the corner teeth; but after a shell-toothed horse has marked, his marks still remain in the nippers, the middling, and the corner teeth. The reason is, that, having harder teeth than other horses, his teeth do not wear, nor lose the black spot.

Amongst the foreign horses, we find a great many shell-toothed horses, and generally the mares are more apt to be so than the horses.

**SHOEING. Natural defence.**—When time was young, when the earth was in a state of nature, and turnpike-roads as yet were not known, the horse needed not the aid of the *shoeing smith*, whom I have termed *an artist*; for the Divine artist had taken care to give his feet such a *natural defence* as it pleased him to bestow; and who among us is weak enough to suppose, or so bold as to assert, that this wisdom is not sufficient to the purpose, in such a state! But, to prevent all supposition and cavil on this matter, let us only look around us, and appeal to our senses: do we not every day see horses, mares, and colts, running about on all sorts of ground, unshod, yet uninjured in their feet, for they do not always take to the hardest ground when at large?

In many parts of the world to this very day, even on the most stoney ground, horses are accustomed to carry their riders unshod; and in this kingdom, I have known several horses that were rode for a considerable time unshod, on the turnpike-roads about London, without any injury being thereby done to their feet; though, in these latter times, this practice is got into disuse, as the roads are become harder, and the horse's services are more urgently required. Moreover, I durst believe, many of our horses might travel their whole life-time, unshod, on any road, if the crust of their feet were constantly rasped round and short at the toe; seeing that, hereby, all feet exposed to contact with hard substances, are thus induced to become more obdurate (or inflexible), provided, at the same time, that the sole be never pared. Whilst some feet, by their extraordinary fine form, depth, and strength, are enabled to resist such roads with impunity, and to support

great weights without breaking. We shall come, presently, to show how these qualities may be impaired, or entirely lost, by bad management.

At this place it is worth our while to stop and inquire whence the custom of shoeing horses arose, and how it should prevail in one part of the world and not in another. In Asia, the original country of the horse kind, they do not shoe their horses at all, because the hoof acquires a tough and firm texture from the dryness of the soil, and really stands in no need of any artificial defence. Further, to aid nature in the re-production of horn of the most desirable texture and hardness, every horseman carries a rasp to shorten the toe, and take off the raggedness of the quarters of the foot, which would otherwise grow too luxuriant, and the crust would most certainly split. On the other hand, horses reared in the Netherlands, for example, or in our Lincolnshire, on wet or moist lands, and a humid atmosphere, will, naturally, have a wider and weaker foot, the consequence of its being replete with cartilage, and therefore capable of contraction by heat, and of expansion by being exposed to damp or wet.

*Iron defence.*—Seeing the great difference that existed in the texture, or hardness of the horn in horses' feet, man in his wisdom—as the surface of the earth changed, found himself obliged to add another defence, besides the natural one, to preserve the crust of such feet as were weak, and therefore not so well able to support them against injuries from hard substances, as stones, roads, &c. This was the “iron defence” we now term the shoe. From the good derived out of this practice, so tried and proved on certain kinds of feet, though, it must be allowed, but a partial good, after all, it is no wonder that the custom of putting shoes on all kinds of feet became general in some countries.

Our ancestors, the original shoers, proposed, in their first efforts, nothing more, it is presumed, than to preserve the crust or wall of the hoof from breaking away, and thought themselves happy that they had skill enough to accomplish so much. The moderns, also, are wisely content with this lowest quantity of the artificial defence, in regard to horse racing, whereby pace, that constant desideratum, was also bettered. But, in process of time, the fertility of invention, and the vanity of mankind, brought forth a variety of methods, almost all of which are productive of

lameness; and I am thoroughly convinced, from close observation and long experience, that nineteen lame horses out of every twenty, in this kingdom, are lame of the artist; which, again, is owing to the form of the shoe, to his ignorance of the designs of nature, and consequent improper treatment of the foot, every part whereof was designed to answer some useful purpose, though it thus appears he does not happen to know it.

But, waving all that these modern artists know, or do not know, I suppose it will be universally assented to, that whatever method of shoeing approaches nearest to the law or design of nature, such is likely to be the most perfect method; and, as the feet of different horses differ from each other, so, if we would arrive at any perfection in this art, the human reason must be employed in discovering wherein this difference consists, and in ascertaining its degree, that each may be treated according to its nature. And yet, with regard to each and all, some general rules may still be followed.

*The foot, its component parts.*—For the sake of those who may be unacquainted with horses' feet, and for their instruction, I shall now describe such parts of the foot as offer themselves to our view, and come under our cognizance, as the immediate and principal objects of our care, when the animal is intended to be shod. These are, the outer sole, the crust, which, like a wall, surrounds it,\* the frog, and bars on each side; and the spongy skin-like substance, which covers the hinder and cellular part of the foot, and constitutes the heel of the horse. Of each of these, I will speak in detail shortly.

With respect to the treatment of these several parts, Mr. Lafosse (to whom the world is indebted for many ingenious observations) has already laid down some excellent rules. And, although, I dare to say, that every man who has tried his “method of shoeing,” is convinced of its impropriety—I mean as a general method, yet some useful hints may be gathered from his doctrine, fitting for our present purpose, whilst the good and evil

---

\* This is the earliest mention we can find of the crust or hoof proper, being denominated the wall of the foot, a term which has now become general among us. It was about the period when Osmer wrote, also, called “the coffin,” whence the principal bone within the hoof acquired the name of *coffin bone*.

of his manner of shoe-making shall be spoken of hereafter. He says, the sole should never be pared; and the reason he assigns, is both obvious and just; namely, that the sole, when not pared, acquires a greater degree of firmness and obduracy, whereby it is better enabled to withstand injuries from extraneous bodies, such as glass, nails, flints, stones, &c.

*The sensible sole* is a very important part of the foot, and the many injuries it sustains, as well as its inability to sustain them with impunity, demands that we should bestow some attention upon it, in this place, though concealed from our sight by the outer sole, that forms the concavity of the foot. This latter is evidently a contrivance of the all-wise Creator, to defend by its obduracy, the inner or sensible sole, which lies immediately within the other, or insensible sole, between that and the bone of the foot, which has acquired, latterly, the term coffin-bone. This inner sole, being no other than the termination of one of the flexor tendons of the leg, which is continued to the bottom of the foot, and, overspreading the bone thereof, takes its oval shape by pressure, as it were.

This tendinous expansion, or sensible sole, when the outer sole is pared away, and the animal put to strong exercise, is, for want of its natural defence, exposed to excessive pain, and is consequently liable to violent inflammation. From this cause alone, the poor creature often limps away from the forge; and many a horse has been rendered lame for ever, under a variety of names, according as the effect thereof may make its appearance on this or that part of the sole, if it do not make its way to the coronet also. If it be asked by any shoeing-smith, what becomes of the sole when not pared away by him? I answer—it dries up, separates, and scales away, acquiring, hereby, the character of being a flakey sole; which kind of sole requires to be deprived of its flakes only, when these are redundant: health prevails when these flakes appear to have formed.

*The frog.*—The same Mr. Lafosse has said, “the frog should never be pared.” His reason is, that the frog, being united to that tendon of the leg just mentioned, as one that is continued down to the bottom of the foot, is itself an elastic body, is placed there as a proper point of support, and serves as a basis to relieve this tendon at each step or motion. But any person of common sense may perceive, if

the frog be pared away, it cannot be admitted to touch the ground, as nature designed it should; for want of which support, the tendon is forcibly elongated and strained; hence, frequent lameness of this tendon is occasioned, and hence, also, windgalls are frequently produced.

As to those tendons, I am aware, that many persons maintain they are elastic bodies, but it is, nevertheless, an error.

For all tendons and muscles are confined to their proper sphere of action; and hence it follows, that, if they were elastic, the force of any muscle of the limbs (the upper and lower parts whereof are tendinous) would be eluded, and fail in its object, before such tendinous part could act according to the will.

Paring the frog has to sustain other objections also. In the first place, if admitted to touch the ground, it helps to stop the horse from sliding, as the figure of it plainly shows. Secondly, the frog with its bars, occupying the hinder part of the foot, is designed by nature to distend the heels, or, as we now say, to keep the heels open; but when cut away, and their strength impaired, this suffers the heels, the quarters, and the coronary ring to contract upon the internal structure of the foot. Hereby another description of lameness is produced, as diseases of the navicula, and of the coffin-joint; neither of which can be ascertained with any degree of precision, certainly not distinguished from each other, to any useful purpose, until after death.

*The bars* are situate between the heel, the frog, and the quarter on each side, and should not be scooped out according to the general mistaken practice, for the reasons just mentioned; because, in conjunction with the frog, their use is to keep open the hinder part of the foot, as well as to defend it. Neither is the spongy, skinlike substance to be cut away until it becomes raggy, because it is the expansion of the skin round the heel, its use being to unite more firmly the foot and its contents; as well as to keep the cellular parts of the heel from growing rigid; it also surrounds and covers the coronary ring, and may be observed to peel and dry away as it descends thence upon the hoof.

*The crust.*—Those are the general rules to be observed with respect to every kind of foot. But, because Mr. Lafosse has said “the frog and sole should never be pared,” many smiths of our country, mistaking the extent of his meaning, have

fallen into another extreme, and do not pare the foot at all. Yet is it quite necessary, that the crust of all horses' feet which are shod should be pared more or less, according to its different degrees of strength; although it must be allowed that no general instruction can be laid down, as to how far this paring is to be carried, because the nature of feet differ greatly from each other, in size, in thickness, and in hardness or brittleness—by which circumstances alone the workman is to be guided. And to prove the necessity of thus paring the crust, it is to be observed, that the ground surface of the crust of every foot—that whereon the shoe rests, invariably becomes rotten in a few weeks; so that, if a new shoe be set upon an unsound foundation, it cannot stand firm or long. In such cases, the crust will also shell off, or break away, leaving large chasms, which the smith in vain endeavours to amend in working horses by turning down an adequate portion of the iron.

Now, as it follows, that where the foot is deep and the sole hollow, the crust is generally thick and strong, such a crust cannot be pared down too low—so as not to fall into the quick; because, if suffered to remain, the strength of the crust alone will occasion such a compression on the interior parts of the foot as to produce lameness—as will be shewn further down.

In all broad fleshy feet, the crust is thin, and should therefore suffer the least possible loss: on such feet the rasp alone is generally found sufficient to make the bottom plain, and produce a sound foundation without employing the desperate butteris, or even having recourse to the less offensive drawing knife. Thus it is each kind of foot should be treated—according to its different degree of strength or weakness.

*The shoe.*—The superficies of the foot round the outside being now made plain and smooth, the shoe is to be made quite flat, of an equal thickness all round the outside, and open and most narrow backwards at the extremities of the heels, for the generality of horses; whilst those whose frogs are diseased, either from natural or incidental causes, require the shoe to be wider backwards. Then, to prevent this flat shoe from pressing on the sole of the horse, the outer part thereof is to be made thickest, and the inside gradually thinner. With such a shoe, it will be seen, the frog is admitted to touch the ground, the necessity of which has

been already shewn. Add to all this, the horse stands more firmly; his feet may be said to take firmer hold of the ground, having the same points of support as in the natural state.

Here, the reader will perceive, is a plain easy method of forming the shoe, agreeable to common sense and reason; being strictly conformable to the anatomical structure of the parts, and therefore in accordance with the design of nature. A method so plain, that one would think nobody could have fallen into any other, or commit any mistake in an art, where nought more is required, than to keep in mind three things, viz.

1. To make smooth the surface of the foot;

2. To ascertain what loss of crust each kind of foot will sustain with advantage to itself; and

3. To nail thereon a piece of iron, adapted to the natural tread of the horse; the design, good, or use of the iron, being only to defend the crust from breaking—the sole wanting no defence, if never pared.

Let us next examine the prevalent manner of shoeing, by comparing it with what has been already said, and we shall soon perceive its sad effects.

*Of adapting the shoe to the structure of the foot.*—Navicular diseases, so called, are brought on, in nine cases out of ten, by bad shoeing; for the modern artist employs very little difference in the treatment of every kind of foot that may come to hand; but with a strong arm and sharp weapon, carries all before him, and takes away more from a weak-footed horse at one paring, than nature can furnish again in some months, whereby permanent lameness is brought on, sooner or later. Whilst, if a strong-footed horse, with narrow and contracted heels, is brought before the smith, such a one meets with treatment still more severe. Thus, under pretence of giving the horse ease, the bar is scooped, the frog is trimmed, and the sole is drawn as thin as possible, even to the quick; and all this is done without mercy, as it is without judgment, in the workman, who assigns as a reason, that the “horse is hot-footed, or foundered, and cutting away will give him ease;” whereas, if the animal were really lame, this treatment would but confirm the evil, and render it more inveterate. How all this is brought about, is only to be ascertained by examining the structure of the foot internally.

In the interior part of the foot (which few or none of those workmen have ever

examined) there is a broad cartilage annexed to each upper end or corner of the foot bone (called by the moderns, coffin-bone); there is also, a small bone, called the navicula, or nut-bone, placed cross-wise in the foot, behind the conjunction of the coffin-bone, and the coronary-bone,\* the ends whereof, are articulated to the inner sides of the coffin-bone, which ends are also cartilaginous; and from the situation, and functions these have to perform in every motion of the foot, it is necessary they should be of a cartilaginous and pliant, or yielding nature.

Now, it follows, that when this same foundered foot (as it is called) is robbed of those parts that were designed to keep it open, the heels and the coronary-ring become contracted more than they were before, by which means those cartilages of the foot-bones I have just described, are more compressed or contracted together. All the membranes and tendinous expansions of the foot, also, are compressed and inflamed, and the cartilaginous ends of the nut-bone, together with the ligaments, are squeezed together as in a vice. Therefore, is it well worth observation, that whenever the heels of a horse are deep or narrow, stricture ensues around the coronary-ring, and such feet fall more or less lame, after some use, and that from no other cause than the compression above described.

*The tread.*—But the modern artists, not content with ruining and destroying the work of Providence, by the means just described, seem resolved that all their operations shall be of a piece, and in every thing act by contraries. To prove that this charge is not hastily made, I will demonstrate, that the kind of shoe in common use, is at variance with sense and reason, as well as contrary to the natural tread of the foot.

In the first place, it is taken for granted, that no horse can go, if the shoe bears upon the sole; but, to avoid this evil, we hear them say, the modern shoe must be formed and stand concave! Therefore

do they make their shoe thinnest on the outside, and thickest on the inside.

Mark, now, the inconveniences arising from the unequal surface of such a shoe! The horse, having, by those means, fewer points of support, is more liable to blunder, to strain the tendons, injure the cartilages and ligaments, break the bones of the foot, and to dislocate some of the joints of the fore part.

The weight of the horse bears chiefly on the inner side of this shoe, which is the highest part; so that the nails next to the heel, when the horse comes to work, must break, or give way, or tear the crust. Hereby the shoe gets somewhat loose, the fine sand of our roads insinuates itself between the foot and the shoe heel, and the horse is then said to be gravelled; or he gets a corn, perhaps, with which he goes lame for life, no effectual remedy being known for this evil.

In the next place, by employing this kind of shoe, though the frog be not pared away, it will be raised to such a distance from the ground, that it cannot be admitted to touch it; by which intervention of the shoe between the frog and the ground, the flexor tendon within the foot loses its support, as much as if the frog were actually pared away, and disorder of the tendon ensues. Furthermore, the heel of the horse is hereby corroded and eaten away, and the crust is also more liable to be broken. Notwithstanding all these facts are so easily ascertained, those men are obstinate and weak enough to affirm the direct contrary, and give it as a reason for making the outside of the shoe thinnest, not perceiving the consequences of such unequal pressure on the crust. Or, we might say, more properly, the total absence of pressure on that part of the crust which most requires it, and which, by its superior hardness, is most capable of sustaining pressure, namely, the outer or external face of the hoof.

Having thus shewn what a variety of lameness is superinduced by the wrong manner of shoeing, I shall leave all that has been said to the sober consideration of my readers, under the expectation that they will try the experiment of a change from what cannot be worse to what may be better—and go on to state my opinions and experience of the improved and, as I think, only proper method of shoeing.

*Shape of the shoe.*—Let the shoe on every description of horse, stand wider at the points of the heels than the foot itself;

---

\* Described by us moderns, as the small pastern; a bone that is big at both ends, small in the middle, the small part being embraced by the coronary-ring, (where the hair of the foot touches the horn), one-half the bone lying concealed within the hoof, the other ascending out of it. The lower end articulates with the coffin-bone, the upper end with the large pastern, forming the fetlock joint.

otherwise, as the foot grows in length, or luxuriantly, the heel of the shoe, in a short time, gets imbedded in the heel of the horse; and this pressure often breaks the crust, or produces temporary lameness, probably a corn.

Let every kind of foot, on being shod, be kept as short at the toe as possible; so as not to affect the quick; for, by leaving a long toe, the foot becomes thin and weak, and the heels low, whereby the flexor tendons of the leg are strained; whilst the shortness of the toe helps to widen the heels, or, as some say, to keep them open and expansive. So, in all thin weak-footed horses, the rasp should be laid on the toe in the like manner, with a view to render it as thick as possible; for, hereby, the whole foot becomes gradually thicker, higher, and stronger, and is thus rendered more capable of resisting injuries, and the wear and tear of travelling. But, in all those feet where the texture is very strong, the rasp may be laid obliquely on the fore part of the foot towards the toe, and the toe itself thinned, whereby compression on the parts is diminished by lowering the strength of the crust. This rasping, however, is to be used with great discretion, lest the crust, being thin, and therefore unable to support the weight of the horse and his load, a sand crack ensue; which frequently follows a too free or unskilful application of this tool, or from the naturally rigid texture of the hoof next to the coronet.

At first shoeing a weak, or thin hoofed horse, on the improved plan, it is advisable for the workman, when he cuts the toe short, to leave it nearly square, merely rounding off the angles with the rasp. Of course, no nails are to be driven into the hoof farther forward than these angles; even in the stoutest hoofs, nor so far in general. By these means, he not only prevents stumbling down hill, but the nourishment that would descend to the toe, now goes to strengthen the heels, and to keep them open. This latter piece of advice applies more to the hinder feet than to the fore ones; because the horn is always thicker at the toe, before than behind, of every individual horse, whilst the quarters are ever thicker of horn behind than before, by reason of the wearing at the toe being greater behind than before; a comparative fact, that teaches us to keep short the toe before, if we would have good sound quarters, cause the horn to fill up, &c.

The heel of the shoe, moreover, on all

strong and narrow-heeled horses, should be made strait at the extreme points; the form of the shoe, in some measure, helping to distend the heel of the horse. For the same reason, the shoe on no horse should be continued farther than the point of the heel.

*On paring.*—It has been said already, that neither frog or sole should ever be pared away; nevertheless, it must be understood, that it is impossible to pare the crust without, at the same time, taking away a portion of the adjacent sole; it is also further requisite, in order to obtain a smooth and even surface, so far as the web of the shoe reaches, but no farther.

The frog, too, will form an exception to the general rule, as it often becomes ragged, and loose flakey pieces will occasionally separate from the body thereof; and this will take place sometimes in one foot and not in the other, arising from the greater heat or fever in the foot so affected, either by reason of some disorder of the lungs falling down thus partially, or by its being the leading leg when the horse is put on his best pace. Whenever this happens, the loose pieces should be cut away with a knife, to prevent gravel lodging therein. But, if this discretionary power of cutting away, be left with the workman, he will be sure to take away more of it at one time, than will grow again in many weeks. The lower point of the frog, towards the toe, should also be taken down whenever it grows too high or luxuriant.

Yet must it be allowed that no precise method of shoeing can be laid down as strictly applicable to all horses alike; which arises from the different nature, form, and texture of horse's feet: but the prejudices of mankind on all such occasions may be worth remarking upon, as having been the let or hinderance to improvement. Thus, one man invents a new piece of machinery, which he finds to be very useful and proper in many respects, and let us add, just too. Hereupon, his pride and self love would fain extend its application to all purposes whatever. In this light, he warmly recommends it to his neighbour, who having tried it, and finding it fall short of the pretensions so set up, he falls into the other extreme, and declares it to be good for nothing. Hence, that which may possess many claims to adoption, when treated with moderation, becomes neglected of those who should be its patrons, and is totally thrown aside. Hence, also,

the perfection of some arts is less extensive than it might be ; and this one of defending the feet of the most useful and most noble animal on earth, among the rest, supremely.

Now, this flat shoe that I have been speaking of, is not to be made with a smooth surface, after the old French fashion, but channelled round, or what is called fullered, after the English manner ; by which form, the horse is better prevented from sliding about, and the heads of the nails are less liable to be broke off—both which inconveniences attend the shoe with the ground surface quite smooth. But so ignorant are these our artists (who say they do not require teaching) that not one of them can make these flat shoes, though a pattern lies before them, for which reason they generally dislike and condemn them.

*Cutting.*—It has always been deemed a difficult matter to prevent horses from cutting, when once they have fallen into that evil way of going ; it is, nevertheless, very easily accomplished, if people will but attend to the causes which produce it. Whoever will be at the trouble of examining the feet of such horses as cut, will, at all times, and in all descriptions of horses, find the cause to be the same ; namely, to turning out their toes, and consequently intruding the inner heel of the shoe towards the corresponding leg and foot. Hence arises the necessity of boots and bolsters, and bandages, round the fetlocks of half the horses trained at Newmarket, to prevent knocking their joints together ; which all our thoroughbreds are likewise liable to incur in training, at strong work, by their manner of turning, especially when the turn is short or hastily made, when it is affected by their passing the fore legs over each other.

Now, by way of remedy, let us examine the cause ; which will be found in the form of the colt's standing to graze. As all the youngers, particularly well bred cattle, are high-mounted, that is to say, long in the legs, they take the grass with an out-stretched foot, whereby it rests mainly on the inner quarter, and this part is worn lowest. This fact is usually disregarded by the breeding farmer ; whence an evil habit of standing is acquired, the toe grows outward, and the foot becomes crooked from the fetlock-joint, downwards—whereupon we say, it points badly.

It may perhaps be repeated, that this habit of turning out the toe is entailed on

certain horses by nature ; that is to say, foaled high before ; or, the leg behind being low set on, or coming too much underneath the body (as happens to filly foals, mostly), which seems to throw up the fore-hand, inordinately. But, whether it be natural or acquired, the immediate cause of cutting is still the same in all horses so afflicted, and depends on nought else than the inside heel being lower than the outside. And, to prove that this doctrine is true, as well as to remedy the evil betimes, let the farrier, as soon as he perceives the colt's toe turning out, pare down the outside of the foot as much as he can ; let this be repeated as often as the foot will allow of it, but leave the inner quarter alone : thus will the animal grow straight on his legs and feet, with the toe pointing forward, and never cut or knock himself about when he comes into use. The crust should also be suffered to grow fullest on the inside of the foot, and the outer part thereof be rasped away as far as can be spared.

By following this method, we may also prevent grown horses from cutting, if the foot be strong enough to bear a sufficient loss ; if not, the substance of the iron defence may be made thicker on the inside of the foot, from the heel to the toe, than it is on the outside ; and, where it is practicable, and shall appear necessary, both those methods may be employed, and each will assist the other in attaining the desired purpose. I have rode a horse treated in this manner several years, and have found it of but little inconvenience to his going, or to his feet ; much depending, in such cases, on the goodness of the hoof itself. In like manner, such of the dealers as are masters of their business, use this kind of shoe to raise the inside of the horse's foot, and make him point, or stand straight on his feet ; the which object being achieved, cures cutting before or behind, or high or low. The purchaser of such a horse, who thinks he has bought a straight-legged nag, is much surprised, and with reason, at the alteration he perceives in him, the first time it is shod in shoes that are equally thick on both quarters.

Our modern shoeing smiths, however, in this as in many other affairs they undertake, act by contraries, and rasp away as much as they can from the inner part of the feet, whereby the outer part of the wall gets stronger and stronger every day, and cutting is superinduced in horses

originally straight-footed, for they are thus compelled to turn out their toes, and then it is the inner heel of the shoe that inflicts the cut.—*From Mr. Hind's late publication of Osmer.*

**SHOEING SMITH.** The shoeing smith, more frequently known by the denomination of blacksmith or farrier, is, unluckily for those who profess it, a business of much greater bodily labour than professional emolument; hence it is, that few, except the very lowest classes of society, can ever be prevailed upon to engage in it. Here then has always been the deficiency so much complained of, and so universally known, with all the practitioners of the old school, acting as smiths and farriers, whether in town or country; and it is much to be regretted, that their original want of education, the means of instruction, and their total ignorance of the properties of medicine, should have hitherto secluded them from every chance of mental improvement, and personal emulation. If we advert to their manners, we find them in direct uniformity with their intellectual capacity; rude by nature, they become cunning by art; unfortunately untaught, it is their greatest pride to become proportionally untractable; and knowing so little themselves, they confidently affect to believe but little is known by others: shielded by which ideal sagacity, they obstinately persist in an opinion of their own, in opposition to every other, or individually determine to abide by no rational opinion at all.

When a candid comparison is made between their dangerous and laborious employment, and their disproportioned emoluments, it must be admitted by every mind of liberality, they are the worst paid for their drudgery of any set of men in the universe. Hence arises that sterile apathy in the business, which is so much the subject of general indignation and universal contempt; and is the only well-founded reason, why there are so few men of education, or intellectual ability, to be found amidst the daily increasing number who profess the practice. Custom, too, has excluded them from any respectable weight in the scale of society; thereby rendering the obstacles to worldly elevation too numerous, and too uncertain, for even the most laudable and spirited emulation to encounter, with even a distant probability of success. These considerations readily reconcile it to reason, why (upon the most moderate calculation, taking the kingdom in general from one

extremity to another) there is not more than one in every hundred, who exists by the practice of shoeing and farriery, that can speak with precision upon the property of the medicine he prescribes; or elucidate, with propriety, the probable process, or ultimate effect, of the operation he recommends.

In such predicament, probably anxious to do good, without the personal power to effect it, they may be impartially considered “men more sinned against than sinning;” and in many instances, much more entitled to the commiseration of the enlightened, than the contemptuous indifference they so frequently receive. Happily, however, for the vocation itself, much more happily for the community at large, improvement in the practice of farriery has at length become an object of national consideration; and the institution has been repeatedly honoured with parliamentary contributions; under which predictive ray of reformation, part of the present generation may probably not only derive future advantage, but live to see the former system rescued from the ignorance and barbarity by which it has been for so many centuries disgraced. The great hazard arising from the practice of the injudicious or ill informed, is their possessing an unrestrained power of plunging into a bold and inconsiderate use of the most dangerous medicines, the present operation and ultimate effect of which they so little understand, and are so absolutely unable to explain.

It is no uncommon thing to hear of bleeding, rowelling, purging, glystering, and blistering, nearly all taking place (with the same subject) within the space of twenty-four hours; and could a thousandth part of the poor unfortunate animals so rashly annihilated, but rise and recite the load of medical combustibles and contrarieties by which they were destined to their long and last sleep, what a complicated history of the *materia medica* would be brought to light, and what a scene of professional knowledge displayed, to form the basis of reformation, with that long list of sublime disquisitionists, who, waving the disgraceful appellations of smith and farrier, are becoming veterinary surgeons in almost every remote corner of the kingdom! One great and almost invincible error amongst the veterinarian fraternity (of whom there are many juveniles now to be seen) is their superficial survey, and hasty decision, in cases of the utmost magnitude; anticipating the prog-

nostic, without even descending to examine the predominant symptoms of disease. Passionately fond of affecting infallibility, they rashly promise more than they find themselves able to perform; and thus by their own weakness, voluntarily exposed, are frequently compelled to retract to-morrow, what they may have most inconsiderately asserted to-day; thereby overwhelming themselves with a load of professional disgrace, from which there seems no sanguine prospect of speedy extrication.

Smiths and farriers in general, being unfortunately ignorant in the peculiar property of each particular medicine, is not a greater misfortune, than their being absolute strangers to the medicines themselves, thereby becoming the standing dupes of adulteration. The warehouses and shops of inferior druggists, it is well known by men of experience, are by no means remarkable for professional purity; in some obscure corner of which is generally a reservoir of rubbish, admirably adapted to the price and practice of farriers, with whom a custom so laudable has been established for time immemorial, and from the palpable pecuniary effects upon both parties is not likely to be abolished.—*Taplin.*

SHOOTING is unquestionably one of the most fascinating amusements in the world, and it is one of those which clings to human nature almost in dotage. The writer has known more instances than one where decrepid old sportsmen, on the approach of the season, have been busied in preparation for several weeks, and some have even procured new guns, though unable perhaps to walk a quarter of a mile! There is perhaps no amusement whatever where success is so anxiously desired, or so confidently anticipated, as by a shooter on the approach of the 12th of August or the first of September; though the disappointments which almost uniformly attend the noviciate are extremely mortifying; yet hope sustains the spirits; every subterfuge is resorted to, on which to fix the blame of miscarriage, while the true reason is studiously kept out of sight:—the powder is bad, or the shot, or perhaps the fowling-piece is crooked; the game rises too near or too far off—every thing in fact will in turn be wrong, or at least be made to serve as a salvo, rather than the real cause candidly acknowledged, namely, lack of skill, or, rather, want of steadiness, in the sportsman.

To acquire the art of shooting flying,

poor inoffensive swallows, are often put in jeopardy: how far this practice is calculated to promote the intended object, we will not pretend to determine exactly; but very little practice will enable a person to become a very expert swallow shooter. The flight of these birds is regulated by the winged insects upon which they feed, and the elevation of the latter is determined by the state of the atmosphere. When swallows fly about ten or fifteen yards from the ground they are easily shot; the distance being completely within reach, and as every now and then they turn, or become stationary for a moment, a slender share of skill is sufficient to bring them down. Every thing that accustoms the tyro to the use of the fowling-piece, will more or less promote the object, and swallow shooting will no doubt assist; but in preference to destroying these very useful birds, whose appearance associates the beauties of spring and summer to the mind, we should certainly recommend shooting at sparrows and starlings, as they are very mischievous, and their flight, particularly the latter, resembles, in some degree, that of a grouse or a partridge. But, allowing that practice of this sort will assist, it will not attain, the ultimate object; nor does in fact the secret or skill consist merely in the dexterity of shooting flying—the alarm which is caused by the sudden spring of game, and the noise which ensues, throw the young sportsman so completely off his guard, and create such a trepidation, that some practice is at least indispensable, before these difficulties can be overcome; nor, until the game is approached with the utmost coolness, the sudden spring, &c. regarded with indifference, and the object selected with deliberation, will the sportsman be able to bring down the object with almost unerring certainty. We will suppose a man to be an expert swallow shooter—let him approach a covey of partridges, prepared to fire—the birds rise suddenly with great noise and confusion, and the swallow shooter will be so completely bewildered, that they are sure to escape; or, if he hit one, it will be merely an accident.

A young shooter, on the first of September, is prepared for the field almost before the gray of morn will enable him to distinguish any object:—he directs his hasty steps to the place where he expects to find a covey. The dog sets, and aware that the birds are almost under his nose, the tyro approaches the important spot with irregular step, and with a palpitating heart—the

dog is motionless as a statue; his master has advanced one step before him, with such an increase of trepidation as to be scarcely able to breathe—the awful stillness of a few seconds is interrupted by the sudden spring and screaming of the covey, and the shooter becomes so confused as to be incapable of levelling at any individual bird, and the whole fly away, leaving the sportsman much chagrined at the disappointment. On the recurrence of several of these disappointments, the dog will become uneasy, and will not hunt with his wonted cheerfulness: the fall of the bird gives as much pleasure to the dog as to the shooter; and a capital dog, if no game be killed to him, will become careless and eventually good for nothing. Practice, however, will soon overcome the obstacles just mentioned; and, with an ordinary share of self command, no person need despair of becoming a tolerable shot. By way of illustration, we will, once more, suppose the young shooter in the field, with two dogs; he perceives one drawing on the scent and settling to a point—let him call out *Toho!* holding up his hand at the same time: the word will induce greater care in the first dog, and if the other should not be aware of the game, he will immediately look about him, and, seeing his master's hand, will keep his position (no matter what his situation may be, either before or behind the shooter) or, to speak as a sportsman, will *back*. We will suppose both the dogs perfectly steady—let the sportsman advance, deliberately, up to the setting dog; and, if the game should not spring, let him go before the dog—if the birds should run, instead of taking wing, he will be aware of the circumstance, by the dog following; but if the dog follows or *foots* too eagerly, he should be checked by the words *take heed!* These are anxious moments; but the sportsman must, nevertheless, summon all his fortitude, and continue as calm as possible, with his thumb on the cock; when the game springs, he should pull up the cock, and select an individual object—if the bird flies straight forward, it is a very easy shot; let the sportsman direct his eye down the barrel, and the instant he perceives the bird on a line with the muzzle, let him pull the trigger; in levelling, however, the aim should be rather above, than below, the object; for the shot, if correctly thrown, will form its centre from the centre of the muzzle of the fowling piece: nevertheless, in this respect, allowance must be made for the trim of the gun, or for the

manner in which it throws the shot, with which I am supposing the sportsman perfectly acquainted. If the bird should fly directly across, or only partially so, and thus describe the segment of a circle, the aim must be directed before the object; if, with a common gun, four inches; with a percussion gun, two inches; supposing the distance to be about thirty yards. The average of shots is perhaps from twenty to thirty yards, though forty is within reach, and even fifty, particularly with a percussion gun. When the bird flies in the shooter's face, as it were, or towards him, he should let it pass before he attempts to fire, or he will be almost certain to miss.

In what manner soever the object might present itself, we will suppose it comes down; and though it should fall directly in view of your dogs, they must not stir. The sportsman will direct his attention to the covey, and, after *marking down*, will proceed to reload. At the commencement of the season, part of the covey will frequently remain; if, therefore, the dogs are not steady on the shot, mischief must ensue. The dogs should not be allowed to follow a winged bird till the fowling-piece is reloaded; the bird had much better be lost than the dogs injured; though very few winged birds will be lost with good dogs.

Let the sportsman be careful, in loading the piece, to keep it at arm's length, and not hang his face over the muzzle. Also, if he uses a double gun, let him examine, whether by any means the other barrel has become cocked—indeed, whether he has fired or not, he ought to see that the cock or cocks are secure, before he places the fowling-piece on his left arm for the purpose of advancing; the fowling-piece should be carried with the trigger forward, and as nearly perpendicular as possible. A gun is a dangerous instrument, and therefore care is indispensable.

In shooting at a running object, the fowling-piece should be levelled forward, as a hare will carry away a great quantity of shot, if struck about the buttocks:—a trifle kills them if hit in the head, or just behind the fore leg.

The great secret of shooting feathered game is the attainment of philosophical calmness: a hare even, whose progressive motion is attended with little or no noise, yet starts so suddenly as to disconcert the inexperienced; but the rising of a pheasant, particularly out of a bush, will not fail to startle any stranger to the diversion: Fabricius of old, who testified no symptom

of astonishment at the sudden appearance of an elephant, would not have been proof against surprise had a pheasant risen before him.

In aiming, the writer has met with several gentlemen, who did not shut one eye, and who, nevertheless, were very fair shots. Savages, in some parts of the world, are very expert with the bow and arrow at moving objects,—the Emperor Commodus excelled in this respect, and with arrows, headed with broad sharp barbs, was able so cut off the head of an ostrich at full speed; yet, neither the native savages, nor the more savage Roman, shut one eye, or even looked down the arrow, but directed their attention to the object. There is a strong sympathy between the action of the hand and the organs of vision, and we have no doubt that by practice the union just mentioned will become so perfect as to produce the effect of almost unerring certainty. In this way, good shots may be accounted for, who regard the object with both eyes, without looking down the fowling piece. Nevertheless, we have not the least hesitation in recommending the practice of shutting one eye.

It may not be amiss to observe that a sort of unconscious or involuntary motion or movement of the arms and body accompanies the level, which should not be checked till after the piece is discharged—if stopped at the moment of pulling the trigger, the bird most likely will fly away. Also, for a very long shot, the level should be higher than usual, as the shot will not fly any great distance before it begins to come downwards. In levelling, the fowling piece should be held firmly to the shoulder, the left hand placed either close to the trigger guard or a few inches in advance: the former is perhaps safer in case the barrel bursts; but the latter will prevent the gun becoming point heavy. The writer always rams *well home*—the powder, in a patent breech, if not more than a proper quantity is used, will always lie loose (and thus ignites much better) as the wadding cannot be forced further than the top of the breech (and the closer the wadding fits the better); the shot should certainly be well rammed. The fowling-piece too will require wiping out once or twice during a hard day's shooting; also, in going out in the morning, it should be aired by firing a little powder: if percussion priming be used, it will be necessary to place wadding over the powder in the barrel, or it will be apt to be driven out unexploded; the force of percussion prim-

ing is so great, that it drives the atmospheric air before it with such violence, as to expel the powder before the fire reaches it.

It sometimes happens that a sportsman may cock the gun, and, not firing, have occasion to let down the cock—in doing which, he should let the cock pass, and, bringing it back to the half cock, make it *tell* well into the tumbler. A gun, (let me repeat it,) is a dangerous instrument, and should be used with the utmost caution.

For partridges, a brace of good dogs is quite sufficient at once; but they should be used to hunt together, and be perfectly acquainted with each other; otherwise they will be jealous, and commit many mistakes. To beat a country in a sportsman-like manner, a person should not go straight through it; but form circles, as it were, traversing well the ground, and taking care to give the dogs the wind as much as possible; at the same time, the sportsman should not be afraid of beating the ground over twice where there is any reason to believe there is game. He who patiently beats and ranges his ground over and over again, will generally kill the largest quantity of game; and will be sure to find it where it has been left by others. A hare will frequently suffer a person to pass within a few yards of her, without stirring; and birds will often lie so close as to suffer themselves almost to be trod upon before they will attempt to rise.

It will be proper to observe, that the shooter should never strike either bush or indeed any thing, with his fowling-piece. Should he use the butt end for this purpose, it is possible the cock may be caught by some branch, and thus cause the piece to be fatally discharged; on the contrary, should a bush, &c. be struck with the muzzle end, the sportsman will be very liable to lose his shot. It is an advisable practice to examine occasionally, in shooting in general, whether by any means the shot has moved.

If the sportsman use a double gun, and has discharged one of the barrels, he should, after ramming the wadding on the powder in reloading, put the ramrod down the barrel that has not been discharged, which will be less trouble than placing it under his arm, or otherwise; he then can put in the shot; and on taking the ramrod out of the other barrel, he can instantly ascertain whether the shot has moved. Care must be taken in pouring the charge of shot down the barrel which the sportsman is loading, that none of the pellets escape down the

other barrel, as by this means the ram rod will sometimes become wedged very fast, and not moved again perhaps without some trouble.

In discharging one barrel of a double gun, the shot in the other will frequently be loosened, if paper or any such pliable wadding be used; but with punched card, this will seldom, if ever, happen: though it is highly advisable to examine, nevertheless, in order to avoid every possible danger.

Horses, where they can be used in shooting, no doubt diminish the fatigue; and if birds fly straight forward, it is very easy to shoot while on the saddle; the same remark will apply, if the birds rise or fly to the left; but the case is very different if they rise and make off on the right—the horse's head must then be instantly turned to that direction, or the game escapes. For this purpose ponies are frequently used, which have been so accustomed to the sport, as to be perfectly reconciled to the firing of a gun. However, on many of the grouse mountains, riding is altogether impracticable; and as to riding amongst inclosures in partridge shooting, it is tedious, and by no means calculated for a keen sportsman.

On an excursion to the Highlands of Scotland, the sportsman should provide himself with every thing necessary, not only to clean his fowling piece, but also to repair those parts which are liable to be broken, or get out of order, such as the breaking of the cock, main spring, &c. as gun-smiths, or indeed any person capable of doing these jobs, are seldom to be met with amongst the mountains of the north. On grouse shooting excursions in general similar preparations should be made.

As to the colour of the shooter's dress, green is supposed to be the best in the early part of the season, and when winter approaches, a kind of light brown, resembling the stubbles: this last colour will be found to answer throughout the year; and indeed it is highly preferable in hot weather, as it is much cooler; or, in other words, it does not possess so much attraction for the rays of the sun.

Grouse shooting is very laborious and requires both judgment and experience, particularly in mountains to which the sportsman is a stranger. As the season is frequently very hot, it becomes highly necessary to be clothed accordingly. The lighter the dress the better, taking care at the same time to let the garments next the skin chiefly consist of flannel. A flannel shirt and drawers are the best that

can be used for this purpose; and ought in fact to be considered as indispensably necessary. Flannel, though so capable of administering warmth, is, notwithstanding, a bad conductor of heat; and therefore, if the sportsman habituates himself to wear it, he will experience but little increase of heat in summer on that account; at the same time, it must be allowed, that nothing will so effectually absorb the moisture which arises from excessive perspiration, and consequently there can be no better preventive against taking cold. Some persons have an aversion to wearing flannel next the skin, and to such we would recommend calico, on account of its possessing a quality of absorption superior to linen. In hot weather, to walk among the heath till violent perspiration ensues, and then to become stationary for a little time (which will undoubtedly sometimes be the case in grouse shooting) is almost a sure method of taking a violent cold, if a linen shirt is worn next the skin; to say nothing of the disagreeable sensation it excites, by sticking to one's back. Short boots that lace close, but which are easy to the legs and feet, are to be recommended: for shoes, when you walk on the mountains, gather the tops of the heath, which will be very apt to rub the skin off your feet. It will be advisable also to rub some tallow on your heels, the bottoms of your feet, and the joints of your toes, before you go out in the morning, which will not only cause you to walk easy, but prevent that soreness otherwise consequent to a hard day's grouse shooting. It need scarcely be mentioned that the liquor flask is a very necessary appendage, to the bottom of which should be attached a tin cup, which will enable the sportsman to allay his thirst by mixing water with his brandy: rinsing the mouth will perhaps be found occasionally to answer the desired purpose: but on no account should cold water be drank alone; the fatal consequences of which, when a person is in a violent perspiration, are well known.

In bad weather, the birds will generally be found about midway on the hills; and in case of very bad weather, the butts of the mountains are the places to which they resort; but in fine weather, they will frequently be found near the tops.

Grouse go to water immediately after their morning flight, which is the proper time to begin the day's diversion: from that time till the extreme heat of the day comes on, good sport may be obtained; as also, from half-past three till sun-set.

Should the sportsman, however, be inclined to continue his diversion in the dead time of the day (which is from about eleven till three) let him be careful to hunt all the deep cracks he meets with, as grouse frequently creep in them to shelter themselves from the excessive heat of the sun; at this time also, they may frequently be found in mossy places.

In this diversion, be careful to give your dogs the wind, and also to try the sides of the mountains which are most sheltered: if it blows hard, you will be certain to find the birds where the heath is longest; and when this unfortunately happens to be the case, they generally take long flights, and these too, are, for the most part, *down* the wind, which is the very reverse of what most other fowls are known to do.

On finding a pack of grouse, the old cock is generally the first that makes his appearance, and the first that takes wing: if he has not been much disturbed, he will run out before the dogs, making a *chucking* noise, and will generally get up and *challenge*, without seeming to testify any fears for himself; but by this he warns the hen and the poults, which immediately begin to run and separate. The hen generally runs as far as she can from you, in order to draw your attention from the poults; and if the latter are strong enough to shift for themselves, she will sometimes make off altogether, in which case, good diversion will generally follow. The main object, however, should be to kill the old cock, in which case you will most likely be enabled to pick up the young ones, one after another, as in the beginning of the season, they lie very close, particularly after hearing the report of a gun, which terrifies them to such a degree that you may sometimes pick them up with your hand from under the dog's nose. When this happens, the ground cannot be too carefully beaten. It frequently happens, however, that the old cock gets safe away, for he is seldom inclined to suffer the near approach of the sportsman. Old cocks may be frequently found sitting alone amongst bunches of heath or long grass, surrounded by water: the bunches of heath or grass to which we allude (and which seem to be a favourite resort of the solitary cock grouse) being situated in plashes or wet places.

It is well known that game, generally speaking, are difficult of approach in wet weather; but the case is somewhat different with grouse, at least in the beginning of the season. A few years ago, the writer was shooting on the extensive moors be-

longing to the Bishop of Durham, near Weardale (August 13, 1822); it came on to rain very violently; and, as he was endeavouring to shelter himself under a huge stone (fragment of a rock), the Bishop's head keeper, Mr. Wm. Rippon, approached for the same purpose. The rain fell heavily for some time, and the heath, of course, was drenched with wet. As the day was far spent, the writer had some notion of retiring, supposing, according to the general idea, that the birds would not lie. In the course of conversation, however, the keeper informed me that this was a mistake, and that after a heavy rain, grouse would *lie like stones*. In order to ascertain the truth of this assertion, the writer immediately sallied forth and met with good diversion. The birds lay so close, that they literally rose under the noses of the dogs, and some suffered themselves almost to be trod upon before they would rise. They were principally single birds, but that, in all probability, arose from the circumstance of the number of shooters on the same moors, by whom the broods had, of course, been scattered.

The writer was somewhat surprised at what was new to him, and directly contrary to the generally received opinion; but the reason is evident: the heath being remarkably wet, the birds could not run; and, as they had been alarmed by much previous firing, they were afraid to get on the wing, and hence the matter seems completely explained. But at a later period of the season, the case would no doubt have been very different; and it may be taken for granted, that game of all kinds are difficult of approach in wet and boisterous weather.

Of all shooting, none is so laborious, either for man or dog, as that of grouse; the sportsman ought, therefore, to be provided with plenty of dogs, in order to rest them alternately; and one brace, or a brace and a half, of good ones at a time, will be fully sufficient.

To insure an abundance of grouse, care should be taken, prior to the pairing season, to destroy a number of the male birds, as, at the close of the shooting season, a preponderance of cocks will uniformly be found. It is well known to sportsmen, that the cock bird is always the first to take wing; he cautiously avoids the approach of the shooter, and hence the reason why so many male birds are always left. If, therefore, at the commencement of the breeding season, more

cocks are left than can find mates, furious battles ensue, much confusion is produced, and the nestling and incubation suffer in consequence.

It is a prevalent opinion that a dry breeding season is detrimental to grouse; this, we conceive, to be a notion hastily adopted, and which will not bear the test of investigation. And, while this opinion is so inconsiderately taken up, it is as strenuously maintained, that the season cannot be too dry for partridges. Now, it appears strange, to say the least of it, that a wet season should be conducive to the health of young grouse, and yet highly detrimental or destructive to young partridges. They are not exactly the same birds, it is true; but they are in some measure allied to each other, while there is a striking similitude in their habits. In a dry breeding season, partridges are sure to be abundant; for a very good reason, their eggs are not chilled by the wet, nor do the young birds suffer, for the same reason; and it will take something more in the shape of argument, that an inconsiderate assertion, or the dictum of ignorance, to convince reasonableness that the case is not precisely the same with grouse. The mountains, distinguished by the name of Westhope Fells, Westmorland, are remarkably wet, and for this reason (according to the prevalent notion) as the season (1820) had been uncommonly dry, they should have produced an abundance of game, or, at least, much more than other mountains, which were equally remarkable for being dry. This was not the case; for, on the 13th of August, when we ranged Bollyhope Fells, which are very dry, I found the grouse much more abundant—in the proportion of four to one.

As grouse, however, are found only in particular parts of the country, the pursuit of these fine birds is by no means so general as partridge shooting. Grouse are out of the reach of Cockney sportsmen; and though many tradesmen, resident in large towns, contrive to enjoy, now and then, the pursuit of the partridge, they seldom venture upon a grouse shooting excursion, on account of the distance, perhaps, as well as the expense necessarily attendant upon it. The Highlands of Scotland abound with grouse, as well as black game; while ptarmigan, or white grouse, are found on the grey tops of many of the highest mountains. But these birds, in Scotland, are not confined to that part of the country, particularly

distinguished by the name of the *Highlands*, as they are very plentiful in other parts—at least the black and red grouse; in the neighbourhood of Nithsdale, belonging, principally, to the Duke of Buccleugh, for instance, these birds appear as numerous as in the Highlands.

In England, red grouse are found in greater plenty in Cumberland, perhaps, than in any other part, and particularly in the neighbourhood of Shap (principally, we believe, the property of the Earl of Lonsdale); they are also plentiful in Westmorland and Durham, and also in Yorkshire: they are to be found on the hills in Lancashire; grouse, both black and red, are to be met with in Derbyshire and Staffordshire, as well as in several other parts of England, but not in profuse abundance. Grouse are also found in both Ireland and Wales.

For several weeks prior to the 12th of August, dog carts may be frequently seen on the road to the North, laden with that sagacious animal, which so essentially contributes to the success of the chase; and, as the time approaches, equipages on a smaller scale may be observed in great numbers, all directing their course to the scene of action. About the 10th or 11th, the roads become crowded with sportsmen and their attendants, who travel principally in gigs, in the bottom of which is generally seen, a convenient receptacle for several pointers. The more humble pursuers of the chase seize the opportunity offered to them by numerous extra stage-coaches, of reaching their destination in time; and thus, by the eve of the 12th, every one is at his post, palpitating with the eager expectation of to-morrow's sport, and uttering the most fervent ejaculations for fine weather.

Grouse, when sent to a distance, should be packed air tight, and not drawn.

We are not aware, that we can give those who have never visited the moors, a better idea of a grouse shooting excursion, than by extracting a page or two from Johnson's "Shooter's Companion;"—"Myself and my companion (says the author) reached Bowes, a small town in Yorkshire, on the confines of Durham, about three o'clock in the afternoon of the 12th (this day falling on Sunday, in 1821, and the shooting not commencing till Monday) and having mounted ponies provided for the purpose, we left the high road, and, with but a slight knowledge of the country, set out in search of a small village, called Chapel, in Weardale, West-

moorland. In order to reach the *point d'appui* as soon as possible, by the advice of a rustic whom we met, we attempted to cross a considerable extent of moorland : for this purpose, we followed a path pointed out to us, and traced it for a considerable time, till at length, it dwindled into a sort of sheep walk, and shortly afterwards vanished altogether. Still we kept onward in the direction that had been pointed out, till, from the lowering appearance of the horizon, threatening unfavourable weather, scarcely sufficient light remained to enable us to avoid the bogs which frequently obstructed our progress. It was but an indifferent bridle road at best ; and as we became enveloped in the dusk of the evening, we found ourselves in the midst of boundless moorlands, dotted here and there with lead mines, which we could but just discover by the aid of the murky twilight ; not a human being was to be seen on this dreary waste. After wandering about for some time, in a state of uncertainty, we discovered through the gloom, at a short distance, two uncouth figures, which appeared to be stalking towards us. They approached, and, like guardian genii, accompanied us to a road (a rough one certainly) by which we ultimately reached our place of destination, at a quarter past eleven o'clock, after a most uncertain and irksome journey. Having made arrangements for the following day, we retired to rest at twelve, and had not been in bed more than an hour, before the trampling of horses, and the whistling of dogs, &c. sufficiently indicated the anxiety of brother sportsmen to be on the mountains at the peep of morn, to see the first rising and flight of a grouse. The mountains in this neighbourhood, rise, for the most part, very abruptly, and to great heights ; they are, nevertheless, much inclined to bog, and walking over them is attended with no ordinary fatigue. We rose a little before two o'clock ; and, after making a hasty, but not a very hearty, breakfast, we mounted our ponies, and, accompanied by our guides, directed our steps up a long, winding, steep ascent, which led to the wished for spot. The weather was hazy, and the gray of the morn enabled us to see the dense fog, which hung, like rolling smoke, in volumes, round the tops of the mountains. No one but a true sportsman can picture to the mind, that eager, that impatient, anxiety which is felt at a moment like this ; particularly as, from report, we had reason to believe that

abundance of game lay before us. But this anxious feeling is not confined to the sportsman :—his dog partakes of it, in a greater degree, if possible, than himself.—The motion of his tail, his crouching curves, his impatient whine, the blandishment of his expressive eye, all confess the delightful anticipations which animate his eager hopes.

Grouse shooting may be placed at the head of what the French would significantly enough call *la chasse au fusil*. In fine weather, nothing can equal grouse shooting : in wet weather it is attended with vexation.

Our diversion in the early part of the morning did not equal our expectations, for numerous parties were scattered over the mountains, and the ground on which we commenced operations, had been already ranged. Several ardent sportsmen had ascended the hills at midnight, ranging the summits of the mountains in order to drive the birds into the vallies, and thus be enabled, the moment the dawn of day admitted sufficient gray light, to commence their amusements at a distance from the fog, which almost uniformly caps the summits of lofty hills, at this time. However, it was not broad day-light, by any means, when a solitary fine old cock cheered our spirits by his chattering, and fell to rise no more. In every direction, the heath was enlivened by the ranging of dogs, an occasional whistle, and the almost continual firing of guns.

We had been led to believe that, the breeding season having been tolerably fine, grouse would be found in abundance ; and this was strictly true ; but yet, for several hours we met with nothing but single birds. I never recollect traversing grouse mountains where the walking was more unpleasant, more irksome, or more fatiguing. The birds were strong on the wing and wild, which, consequently, rendered the pursuit much more laborious ; in fact, the fatigue was excessive, and at eleven o'clock we sat down to lunch beneath enormous masses of awfully projecting rock ; and, with our heads reclined against one of these *solid*, not *downy*, pillows, we enjoyed a very comfortable nap. And here young sportsmen should be cautioned against lying at full length, or sleeping, on the ground, unless it be uncommonly dry, as well as against drinking cold water, when heated, to excess ; it being better to alleviate thirst by a little diluted spirit, or if the flask should be prematurely exhausted, by washing or rinsing the mouth

at the first spring or rivulet. The most fatal consequences have often resulted from a disregard of these precautions. Like giants refreshed, we sprung from our slumbers, and pursued our sport till we could no longer distinguish the flight of a grouse; better success than we had expected to meet stimulated exertion, and left us no time to think of fatigue. As the evening closed in, however, we sought our ponies in the valley below, and, although they were not more than a few hundred yards off, we could scarcely reach the spot from excessive fatigue. Arrived at our homely inn, we made a hearty supper, took a cheerful glass, talked over the day's sport, and threw ourselves into the arms of Morpheus, who strewed his poppies over us without much solicitation. On demanding our account in the morning from 'mine host,' we found that his name should have been '*Woodcock, by the length of his bill,*' his charges very much resembling those of *Peacock* at the London Tavern, although the accommodations were of a very different description."

In fact, the grouse shooting season is considered as a harvest by the publicans and miners also, who reside in the immediate vicinity of the mountains; and every species of imposition is practised with the most unblushing effrontery; but perhaps of all places, there is not one where imposition assumes a grosser form, or is more successful, than in that part of Stainmoor, in the neighbourhood of Bowes (Yorkshire). To say nothing of the extravagant and shameful charges exacted by the publicans, there are a set of lounging fellows, who offer themselves as attendants on the moors; and should these be thought necessary, it becomes an indispensable part of the sportsman's business to make a bargain beforehand, or he will subject himself to the most outrageous imposition. These fellows will demand as high as ten shillings per day for their services, and if not well looked after, will run a score of ten shillings at the inn (if such places can be called inns, which, however, is a gross misapplication of the term). The moors in these parts are free; and in consequence, numbers of novices annually arrive, who immediately fall into the snares, as it were, of these harpies. Jolly Briareus, one of these ruby faced landlords, watched the arrival of his prey with more than ordinary expression of countenance. On the approach of the 12th of August, this ruddy carbuncled Bonniface

placed himself in front of the house almost incessantly, on the look out for the *pigeons* (as he was pleased to term them) with a longing leer on a countenance, so difficult to define, and yet so significantly expressive, that those who ever watched its workings for a few seconds, would ever afterwards retain on their memories, its indelible impression.

The neat little town of Bowes, as well as Old and New Spittle, two or three miles distant, may be regarded as a sort of general rendezvous for those sportsmen who either do not choose to ask, or are unable to obtain, permission to range more strictly preserved domains. At this place there is a great extent of moor, which is claimed by a number of proprietors, who possess no paramount right, and therefore are unable to prevent a general unsolicited range, which uniformly takes place. At the same time, the mountains are much better travelling than they will be found in many other places, and, being surrounded by excellent preserves, scarcely ever fail to abound in game. Spittle is also a general resort for dog dealers and *dog stealers*; and the sportsman who visits this neighbourhood unprovided with this very essential assistant in the chase, may be accommodated exactly according to his means, or the price he is willing to give. But, though this may be a general practice, it is one more honoured in the breach than the observance; and those sportsmen who depend upon such suspicious means, will hardly fail to experience disappointment.

During the whole of the season, grouse are regularly conveyed by the stage coaches to all the large towns, and particularly to Manchester and Liverpool. For this purpose there are certain days appointed, when quantities of these birds are brought to particular houses by the road side, at which the coachmen and guards call; and this unlawful traffic is continued with as much regularity, if not with as much publicity, as the authorised dealing in any other species of marketable commodity. Abundance of game is thus conveyed from Yorkshire, and the northern parts of England, to places situated at a distance, or more to the southward; and when the weather becomes cold, and the game will keep, considerable quantities are brought from Scotland.

As to the dog best calculated for grouse shooting, various opinions will be found to exist, some preferring the setter, and others the pointer. Although excellent

dogs of both kinds are to be met with, there are some leading characteristics which eminently distinguish the long and the short haired dog. The setter is a hardy, impetuous, unruly animal; which, if taken into the field when very young, will frequently set intuitively; but no sooner does he acquire strength than he shews a turbulent spirit, and can only be kept sufficiently obedient by constant exercise. On account of their long coat, setters are more affected by heat, and, consequently, sooner become thirsty than their sleek, thin coated rival; and, in very dry weather, suffer from want of water on the grouse mountains. The well-bred pointer, on the contrary, is a docile creature, very easily reduced to obedience, and, when once well trained, requires neither very hard work, nor severe correction, to keep him submissive and tractable. The pointer, however, is more liable to become foot sore, either from the wiry lacerations of the heath, or from running upon hard and stony ground; consequently, in a sharp frost, he is unable to hunt: the olfactory organs of the pointer are unquestionably superior to, and more acute than, those of the setter; and he will generally be found pre-eminently conspicuous in a harsh dry wind, blowing from north or north-easterly directions, at which time, the scent will be found very difficult of recognition.

We are of opinion we cannot finish the highly interesting subject of grouse shooting in a more satisfactory manner, than by the following interesting letter, which appeared in the *Annals of Sporting*, vol. 2, p. 298:—it was addressed to the editor, and ran thus:—

“Sir—you must know that I am but a young sportsman at present; a mere novice in the science of shooting; till the present season, I never saw a grouse on the wing: but, being ardently attached to the sport, I determined on visiting the moors of Yorkshire, though my residence was at the distance of almost two hundred miles. For a month before the 12th of August, I could scarcely think of any thing but the moors, of which, however, I had formed a very erroneous idea. I thought they must bear some resemblance to Charnwood Forest, in Leicestershire, and was never more surprised, that when, on reaching Yorkshire, I beheld the very different aspect presented by the abrupt and mountainous moorlands, to the plains and gentle ascents of the forest just mentioned. If I saw no “cloud-capt towers,”

I beheld, very plainly, cloud-capt hills: for the first time in my life, I saw the summits of the mountains enveloped by the clouds, beneath which, the dark and sombre hue of the lower parts of these heathy hills, conveyed, at the distance of a mile, a very fallacious idea of their real form and appearance.

“I experienced all the anxiety felt by sportsmen, on the approach of the 12th of August. I arose at midnight, between the 11th and 12th, and ascended the mountains before I could discern the flight of a bird: up to this moment, I had never seen a grouse on the wing (as I have above observed) and I now heard them chatter for the first time in my life. It was the gray of the morn; and I could hear these birds, in various directions, and observed several variations in their cry or call, one of which was an excellent imitation of the words “*come back! come back! come back!*” These matters may appear trifling to an old grouse shooter, but they were quite new to me, and forced themselves on my attention; my situation was altogether novel; nor do I think any thing can be more interesting to a young sportsman, who visits the moors for the first time, than listening to the calling of the grouse a little before day light.

“Almost up to the knees in ling or heath, I commenced my operations. My dogs, though excellent, were strangers to grouse shooting as well as myself, nor did they at first seem to relish the diversion:—they run into the first pack or brood, and raised it out of distance; six dark coloured birds rose, and skimming over the top of the heath, were quickly out of my sight: indeed, in colour they appeared so nearly to approximate the ling over which they flew, that they proved a puzzling mark for me when they were completely within gun shot. More birds were raised in a similar manner; and I soon discovered that grouse must be approached with much more caution than partridges; I also found that they rose in a different manner, and that the sport was not at all similar to that of the midland counties.

“I was extremely anxious to kill a bird: I fired six shots, and had the mortification to see the birds uniformly fly away: indeed, when I pulled the trigger, I was always in doubt, for I could not discern the object half so clearly as if a partridge had been before me. I met, at length, with several grouse not half grown, and was fortunate enough to break the

wing of one of these *squeakers*! I seized the prize with eagerness, but it was very young, very small, unsatisfactory in every point of view, and only served to increase my vexation. I began to lament that I had visited the moors; that I had made so long a journey to seek diversion which now appeared to me so inferior to what might be obtained at home; and, to add to my chagrin, while making these irksome reflexions, I happened to get *ingulphed in a bog*, nearly up to my middle! I could not help venting my grief aloud: I cursed my own folly, for having undertaken a journey of *two hundred miles*, which I now conceived could not fail to end in the bitterest disappointment. With the assistance of my attendant and guide, I got tolerably well cleared of the wet and filth which adhered to my cloaths when I emerged from the bog, and I hesitated for some minutes whether or not to quit the mountains, and immediately return home: the idea that my friends would have *the laugh against me*, alone determined me to continue for some time longer upon these dreary and uncultivated wilds.

“An hour or two elapsed, during which, I fired repeatedly, but was not fortunate enough to bring down a bird. Arrived at a spring of fine clear water, I sat down in despair, determined, after taking a little refreshment, to leave the moors and return home. I had been walking over broken and boggy ground for some hours, sometimes nearly up to my knees in ling, sometimes up to the ankles in dirt and water, had crossed a number of deep and yawning ravines, been once nearly smothered in a bog, had ascended a number of steep hills, and was, in fact, become completely fatigued, as well as severely mortified by a succession of unlooked for disappointments. However, I had scarcely seated myself when the *chattering of a grouse* attracted my attention: I observed the bird approach: I rose—it was crossing me at the distance of thirty or forty yards—I fired—it fell! I ran to the spot with all the eagerness of ardent expectation. I seized the prize with rapture—viewed it with delight. I instantly felt a full flow of spirits—my fatigue had vanished, and I determined on continuing my range, regardless of the fine clear spring, and my late intended refreshment.

“The bird I killed was a fine old cock; and in the course of something less than an hour, I succeeded in killing three other

young, but fine, birds. My spirits were now raised to the highest pitch of exultation, and I felt confident that, before night, I should bag at least *ten brace*. I did not, however, realize these sanguine expectations; but, with more than half the number, I quitted the mountains, at seven o'clock, delighted, after all, with my day's diversion.

“On the second day I commenced my operations with renewed vigour, and was more fortunate than on the first. I had become, in some degree, accustomed to the rising and flight of the game—I could distinguish it better; I became also, in some measure, familiar with the mode of traversing the mountains; and, after spending a few days more in this way, I returned home with this conviction, that grouse shooting is very laborious, but that it affords, at the same time, *the finest diversion in the world*.”

*Partridge Shooting*—The best time for this diversion is from two hours after sunrise until eleven o'clock; and from half-past three o'clock until it is dark. When the weather is very dry, especially at the beginning of the season, as soon as the sun becomes very powerful, the scent is dissipated, and the dog's abilities are put to the test to no purpose. In the middle of the day, partridges cease to feed or run, and place themselves by the side of some sunny bank in order to bask.

Such is the impatience of sportsmen on the morning of the first of September, that they sally forth, and commence operations generally before they can well discern the flight of a bird; yet it rarely happens that much execution is done in this very early part of the morning; and the writer feels a perfect conviction, that if the sportsman could prevail upon himself to wait till eight o'clock, that his day's diversion would be much more satisfactory; he would experience much less fatigue; and, nineteen times out of twenty, would bag more birds. The same observations are equally applicable to grouse shooting. Game, either from the empty state of the stomach, or some other reason, is not easy to approach at a very early period of the morning, though in a few hours afterwards, it will lie as well as possible. When birds are driven from their ground, or usual haunts, early in the morning (at four or five o'clock, for instance) the ground should be visited again sometime afterwards, as the birds are sure to go back.—A sportsman who goes over a certain extent of country at four or five

o'clock in the morning, may perhaps not bag a bird; another, following the same track, at eight or nine o'clock, will be very likely to experience good diversion.

In general, partridges have their separate feeding and sleeping places; but it frequently happens, that they remain all day or all night where they fed the preceding evening or morning; yet it much oftener happens that they change their ground. At day break, they quit their sleeping place; they run, and soon afterwards *call*; and, when collected, generally take their flight to the stubbles, which, if high and thick enough to afford them shelter, will most likely induce them

to remain there for some time: however, in dry weather in particular, they are frequently to be found at this time among potatoes or turnips. As soon as the sun becomes very powerful, or towards ten or eleven o'clock, they place themselves on the south side of some bank or eminence, to bask, where they will remain for several hours, if undisturbed. They seek the potatoes and turnips, towards three o'clock, or perhaps earlier; feed in the stubbles again in the evening, afterwards call, and seek the place where they intend to remain for the night. When partridges are calling, they seldom lie well; or, in other words, they will not permit the sportsman to approach within gun shot.

My pointers *stand*;

How beautiful they look! with outstretch'd tails,  
With heads immoveable, and eyes fast fixed,  
One fore-leg raised and bent—the other firm,  
Advancing forward, presses on the ground.

FOWLING, a Poem.

We must again draw from Johnson's "Shooter's Companion:"—the author observes, "Although I have been a sportsman for more than twenty years, I still retain much of that feeling of anxious anticipation in which young shooters indulge themselves on the eve of the first of September, and which arrives at its greatest height when the gray dawn of the next day appears, but which is seldom realized by the events which succeed. Young and indifferent shooters, on this occasion, calculate on performing wonders; and, in order to qualify themselves for the sport, they generally, for several preceding weeks, practise at swallows—'a custom more honoured in the breach than the observance;' for a person may become a most expert swallow shooter, and yet not bring down a partridge once in a dozen shots: and nothing can be more ill advised, and even cruel, than the worse than useless slaughter of these birds, which daily destroy millions of noxious insects. The flight of swallows is quick and capricious, and yet their destruction is easily attainable by the fowling-piece. The sportsman takes his station with calmness and even *non chalance*; and, selecting his object from the number that are fluttering around him, deliberately waits for the precise moment, when his victim may be destroyed with almost unerring certainty. With *game* the affair is quite different; the object is larger, much larger, but the exact spot whence it will spring is not ascertainable, while the sud-

den rush, and noisy confusion accompanying the rise, so astonish the tyro or the bungler, that the fowling-piece is discharged not only too soon, but generally at random. Hence it will easily be perceived, that little or no analogy can exist between swallow shooting and partridge shooting. The secret of shooting may be easily explained, as it is comprised merely in *coolness* and *deliberation*; these, however, are not so easily attained, as the superficial observer might be led to suppose.—A friend of mine (continues the author) who has followed this diversion for forty years, still continues a very indifferent shot: the rise of a covey never fails to dissipate his previous mental resolves, and he has, nineteen times out of twenty, the mortification of seeing the game go away untouched; but it must be observed, that, to say nothing of his firing too soon, he has contracted a habit which must for ever preclude any thing like certainty in shooting:—no sooner does his finger touch the trigger, than he *shuts both his eyes*! And yet, though conscious of this preposterous defect, and aware that if a bird fall from his gun, it is merely the effect of accident, should he be shooting in company, and happen to fire at the same time as his companion, he will not fail to claim the merit of having *killed the bird*: indeed, to judge from his conversation over the bottle, a stranger would suppose, that, as a shot, he was equal to Sir John Shelley. I have seldom met with a bad shot who was not extremely

anxious to be thought otherwise ; and who would not, in his cups, relate, with much self-satisfaction and infinite glee, a hundred shooting exploits which never had existence but in his own prolific brain."

The moment the light of the morning will enable the young shooter to discern the flight of a partridge, he is impatient to rush to the scene of action, and is all uneasy eagerness—while his more experienced companion finishes his breakfast. The resort of a covey or two is previously known; the sportsmen therefore direct their steps to an appointed spot, where the dogs come quickly to a point. The shooters advance—the tyro with trepid

eagerness and a palpitating heart;—his veteran companion with philosophic coolness. They arrive at the desired spot abreast of the foremost dog; and, for a few seconds, in almost breathless anxiety, nearly choaked with expectation, the tyro expects the game to spring:—the covey rises with screams and confusion, and, at the same instant, the tyro's gun is ineffectually discharged—while his companion, deliberately selecting his object, with one eye shut, and the other steadily directed down the barrel, the bird no sooner appears at the end, than the trigger is drawn, and the partridge falls. The scene is thus described by the author of Fowling:—

Full of th' expected sport, my heart beats high  
And, with impatient step, I haste to reach  
The stubbles, where the scatter'd ears afford  
A sweet repast to the yet heedless game.  
How my brave dogs o'er the broad furrows bound,  
Quart'ring their ground exactly. Ah! that point  
Answers my eager hope, and fills my breast  
With joy unspeakable. How close they lie!  
Whilst to the spot, with steady pace, I tend:  
Now from the ground, with noisy wing, they burst,  
And dart away. My victim singled out,  
In his aerial course falls short, nor skims  
Th' adjoining hedge, o'er which the rest unhurt  
Have passed.

Sportsmen are occasionally to be met with, who, in taking aim, use both eyes; and others again will be found who declare that they look directly at the bird, regardless of running their eye down the barrel of the fowling-piece; but we are of opinion that it is scarcely possible to become an expert or dead shot, without closing one eye and taking a deliberate aim down the gun barrel with the other. At least, we recommend this plan in preference to all other modes; though we are aware that practice will do much in any way; and that good shots may be met with who adopt a different mode.

*Pheasant Shooting.* In this diversion the sportsman should be properly equipped for a cover; and, in our opinion, strong woollen cloth gaiters or leggings are preferable to leather, as, in wet weather, the latter are very uncomfortable, and the former are a sufficient guard against the briars, &c.

If the night before you shoot be wet, the droppings of the trees will compel the pheasants to quit the woods; and in this case the hedge rows and furze covers should be tried very carefully, and good

sport will most likely be obtained. This bird is much attached to almost all sorts of covers, especially to the sides of pits where alder trees are growing.

Of all dogs, none are so good for this sport as the setter. Pointers are frequently too tender to follow this bird through the brambles, which is not the case with a good setter; but care should be taken never to let them range out of gun shot. We are perfectly aware that different opinions exist upon this subject; and perhaps the greater number of sportsmen prefer the springer for pheasant shooting, and this little dog, when well trained, will no doubt, answer the purpose, particularly at the commencement of the season, or where the birds have not been much disturbed; but we think the springer too noisy for this diversion, and therefore prefer the setter.

In hedge rows, pheasants lie remarkably well; and, in this case, a pointer or setter will of course make a very steady point, and the bush must perhaps be shaken before the bird will rise; but it is different in covers, where these birds frequently run a considerable distance, and

it becomes necessary to encourage the dog; though one a little used to this sport will need no encouragement.

Pheasants are frequently slaughtered wholesale, in what are called *battues* (which in this case, means a collection of shooters, who proceed on each side the cover, while dogs and perhaps men also, are employed to drive the birds from it) and in such case, no better dog can be used than the springer. Battu shooting is only practised where there is a great abundance of game. The writer has seen (and such a practice he believes is followed at Mr. Willis's of Halsned, near Liverpool) pheasant shooting with one springer only, and the dog had been taught to fetch the bird when killed; but it was where the birds were chiefly found in small covers which fringed the borders of pits.

Naturalists observe, "of all game birds, pheasants are shot most easily, as they always make a whirring noise when they rise, by which they alarm the gunner, and, being a large mark, and flying very slow, there is scarcely any missing them."

"Ah! what avail his glossy, varying dies,  
His purple crest, and scarlet-circled eyes,  
The vivid green his shining plumes infold  
His painted wings, and breast that flames with gold."

The hen pheasant, when pushed, seldom rises so high as the cock, or yet takes so long a flight. A cock pheasant will sometimes fly to a considerable distance; and whenever this happens, as the act of flying is very laborious to this heavy bird, he is not able to rise again for some time. If the sportsman can mark down a pheasant after one of these long flights, and hasten to the spot, he will find the bird to rise with great difficulty, and fly to a very short distance, or, perhaps, he will be unable to rise at all. Indeed, pheasants seem conscious of their incapacity to maintain a long flight, and therefore prefer running wherever practicable, in preference to taking wing; however, after a long flight, they are difficult to find, as, on these occasions, they generally drop into a bush or thicket, and remain for a considerable time (if undisturbed) without moving.

*Woodcock Shooting.* Woodcocks arrive in Great Britain in flocks; some of them in October, but not in great numbers till November and December, though they are sometimes seen as early as September. They generally take advantage of the night, being seldom seen to come before

The sportsman cannot but smile at this last sentence. A pheasant is easily shot by an old experienced practitioner; but we much doubt whether the tyro stands not a much better chance of success when a *twiddling* snipe rises before him. That the pheasant is a "*large mark*" every one will readily allow; that its flight is by no means rapid, is equally incontestible; but the tremendous bustle and whirring noise which these birds make in rising, so agitates the inexperienced shooter, that he not only fires too soon, but generally without taking aim, and has to endure the mortification of seeing the bird fly away unhurt. A cock pheasant, when *pushed* from a bush or thicket, generally rises perpendicularly till he has cleared every obstacle, before he goes off horizontally. The moment for shooting is when he assumes the horizontal direction. If a novice in the art fire at the bird while he is rising, he will, in all probability, throw the shot below the bird. With an experienced shot, the mode of rising is of little consequence.

sun-set. The time of their arrival depends much upon the prevailing winds; they are unable to struggle with the boisterous gales of the northern ocean, and therefore wait for the advantage of a favourable wind.

They feed on worms and insects, which they search for, with their long bills, in soft grounds and moist woods, feeding and flying principally in the night. They go out in the evening, and generally return in the same direction, or through the same glades, to their day retreat. This at least is the generally received opinion; but it requires elucidation:—the fact is, the bird is on the wing at the very dawn of the morning, and feeds as soon afterwards as he can discover food; he will then generally continue in the place where he has fed, if sheltered, or seek the protection of some cover or hedge; and, if undisturbed, will remain in the same situation till late in the afternoon, when he feeds again, and afterwards takes a short flight or two to his resting place for the night.

The greater part of these birds leave this country about the latter end of February or the beginning of March. They retire to the coast, and, if the wind be

favourable, set out immediately: but, if contrary, they are often detained some time, and thus afford good diversion to those sportsmen who reside near the sea.

Woodcocks generally weigh from twelve to fourteen ounces, and are chiefly found in thick covers, particularly those with wet bottoms; and they are very fond of sitting under holly bushes; they are not, however, fond of covers where there is long grass growing in the bottom and at the roots of the trees.

The sight of the woodcock is very indifferent in the day time, but he sees better in the dusk of the evening and by moon light; and it may also be remarked that woodcocks will lie much better the day following a moon light night, than when it has been preceded by a dark one; the reason is obvious—the bird has been enabled by the light of the moon to make a plentiful repast, and the next day is lazy and unwilling to fly; whereas, when the darkness of the night has rendered it impossible for him to satisfy the calls of hunger, he is constantly uneasy and on the alert in search of food, which he never attempts to seek in the day time, but when constrained by necessity.

Shooting woodcocks is a very pleasant amusement in woods which are not too thick; and, if they are cut through in several places, it renders it more easy to shoot this bird in his passage when he rises, and also to mark him with greater certainty; and woodcocks will generally be found near the openings or roads in the woods, if there be any. In this diversion, a good marker is of essential service; as with his assistance it will be difficult for a woodcock to escape; as he will generally suffer himself to be shot at three or four times before he takes a long flight.

Springers are frequently used for this diversion (see the article Spaniel) and of course give notice by their barking when the cock rises: these animals, when well trained may answer very well; and in fact they are better adapted for this amusement than for pheasant shooting.

The woodcock is a clumsy walker, and rises heavily from the ground; when he is found in an open field or a hedge row, in the pass of a wood, or an unfrequented one, he generally skims the ground slowly, and is very easily shot; in fact, under such circumstances, he is the easiest of all birds: but it is occasionally otherwise, particularly when he is flushed in a tall wood, where he is obliged to clear the tops

of the trees before he can take a horizontal direction.

*Snipe Shooting.* This diversion is by no means so interesting as those which we have already described under the present head; but it may wile away an idle hour when superior sport cannot be obtained. There are three different sizes of the snipe, the largest of which, however, is much smaller than the woodcock. The common snipe weighs about four ounces; the jack snipe (or judcock) is not much larger than a lark; the great or solitary snipe weighs about nine ounces, but is seldom met with.

Snipes are to be found all the winter in wet and marshy ground, particularly where there are rushes; they are frequently met with in mountains and moors among the heath; but a severe frost forces them to the springs and running streams. Numbers of these birds remain with us all the year, and breed in our marshes, laying generally six eggs the latter end of May.

The snipe is generally regarded as a difficult shot; and it must be allowed that it requires practice to surmount this difficulty, which arises from the zig-zag manner in which the bird flies immediately after getting up. The best method to pursue in this diversion is to walk down the wind, as snipes generally fly against it; and if a snipe rise before the sportsman, it will not fly far before it turns, and describes a sort of semi-circle, which will afford more time to take aim, by thus remaining longer within gun shot. If, however, the bird should fly straight forward, it will be highly proper to let it get some little distance, as its flight will become much steadier. The slightest wound is sufficient to bring these birds to the ground.

An old pointer is the best for snipe shooting. To accustom a young dog to snipes slackens his mettle, and renders him of little use for partridge or grouse, owing to getting a number of points with little exertion. However, when these birds are plentiful, a dog is scarcely necessary, as walking them up will answer equally well.

Something less than two centuries ago, what is now termed poaching was the gentleman's recreation; no person shot flying; and even within the last hundred years, or little more, an individual, who exercised the art of shooting birds on the wing, was considered as performing something extraordinary, and many persons requested to attend his excursions that they might be eye witnesses of it. Since that period, however, the practice gradually

became more common, and may at present be regarded as universal.

In the early part of the present article, we expressed our opinion as to the best method of acquiring the art of shooting flying; but as the subject possesses much more than ordinary interest, particularly to those who are young in the art, as well as to those who have practised for a considerable period without acquiring satisfactory skill, we shall here introduce another opinion on the subject, elucidating such parts, with our own remarks, as seem to require explanation, or appear to be founded in error.

“In shooting, it is to be remembered, that the hand is to obey the eye, and not the eye be subservient to the hand. *Both eyes should be open*, and the object fired at the instant the muzzle of the gun is brought up, and fairly bears upon it; the sight being weakened by a protracted look along the barrel at a bird, and it is for this reason that birds which spring at the marksman's feet, and fly off horizontally, are frequently missed; his keeping the aim upon them so long fatigues the eye, and the finger does not obey the eye so readily as when employed at a first glance. It is not here meant that a bird is to be blown to atoms as soon as it tops the stubble, but that a marksman is first to make himself a thorough judge of distance; with that knowledge, in open shooting, he will never put the gun to his shoulder until the bird has flown a proper length, and then fire the instant a sight of it is caught.”

We have already noticed the method of taking aim with *both eyes open*, and we here again assert that we consider it as a mistaken notion. Let any person point a gun to a fixed object: by shutting one eye, and directing the other down the barrel, he will easily perceive when the level is true; by directing both eyes down the barrel, he will not only perceive a degree of confusion, as it were, but the aim will be with more difficulty, as well as more uncertainty, directed to the object. Nevertheless, we are willing to admit that there are persons who shoot remarkably well, who keep both eyes open, yet, let it be observed that a rifle man or sharp shooter always closes one eye; if, therefore, the latter method is preferable with a ball, why not in shooting at game with shot?

To kill birds flying across either to the right or left, allowance must be made by the shooter both for the distance he is from them, the strength of the bird, and also

for the velocity of the object itself. The motion of a partridge, for instance, in November, will be greatly accelerated to what it was two months before. Practice alone can teach these minutiae, which, if fixed at any given space, or attempted to be uniformly regulated upon paper, might lead the shooter erroneously in the field.

It may not, however, be amiss to remark, that, in a cross shot to the right, the difficulty is much increased if the right leg be first when the bird rises; the gun cannot then be brought but a very trifle beyond a straight line to the right; and sportsmen frequently stand with their feet so far apart when in the act of firing, that it effectually prevents them from bringing their fowling-piece to bear properly upon a crossing object. When dogs point, and when game has been marked and is expected to spring, the progressive motion should be with short and easy steps; the body can then be easily turned upon the legs, as upon a pivot, and the bird commanded even if it should fly quite round the sportsman.

And after all, the science of aiming accurately will be of little service, except the gun is held steady from all starting and flinching at the moment of pulling the trigger; it is to little purpose for a sportsman to traverse the gun with the celerity of a bird's rapidly flying across, if he suspends that motion when he fires. Quickness of sight and steadiness of aim will never constitute a good shot, unless the motion of the gun corresponds with them.

In shooting with any person who keeps his gun cocked and the muzzle usually pointed to the left, carefully keep to the right of him; be careful in getting over or through a fence; and if a shooter beats bushes with his gun, get out of his company as soon as possible.

In the house, as well as in the field, a gun should always be considered as loaded; nor should it ever, for one moment, be pointed towards a human being.

*Pigeon Shooting.*—Those who feel anxious on the subject of pigeon shooting, could not fail to be highly gratified by a visit to the Red House, at Battersea, where the business is pursued in the first style of excellence. The reader need hardly be told that, in pigeon shooting, the bird is placed in a trap, (at a certain distance, as previously agreed upon,) from which it is set free, at a given time, and fired at by the sportsman. Mr. Osbaldeston, Lord Anson, Captain Ross, Mr.

Shoubridge, Lord Ranelagh, &c. may be classed amongst the first of modern pigeon shooters; though the very best of their performances have scarcely equalled those of the late Richard Toomer,\* who, for a wager, shot six pigeons, out of ten, with a single ball. This man and his brother Edward, have been known to shoot at pigeons, from a trap, with their rifles and a single ball, and to kill eight birds out of twelve, shooting alternately, and one of the pigeons, that did not drop, had its legs carried off by the ball. They have likewise, with a single ball, struck twice out of four shots, a cricket ball thrown into the air. The exploits which R. Toomer performed in shooting, with such apparent ease, soon convinced the persons who saw them, that they were done *methodically*; and this was completely ascertained by his frequently suffering himself to be blinded with a double handkerchief over his eyes, after having taken his aim, and then to fire and hit a small object.

*Rook Shooting.*—At a period of the year when field sports cannot be pursued, rook shooting may be enjoyed as a sort of semi-diversion. The rook, it is well known, is one of our very earliest birds in forming its nest; and the production of its young seems to experience no injury, except from very high winds, and very rarely even from these, as the bird contrives to fasten its nest so strongly to the branch upon which it is formed, that it is but very rarely blown from its situation. Plenty of young rooks may, therefore, be generally expected. The middle and latter end of the month of May is the season for rook shooting. As soon as the young birds have acquired sufficient strength, they sit, or perch, on the sides of the nest, and on the neighbouring branches, and thus form a conspicuous object for the shooter. The air-gun and the cross-bow are the engines generally used for this amusement, the former of which is preferable, not merely on account of its superiority in taking aim, but also inasmuch as it is attended with less trouble and less danger. In drawing up the string of the cross-bow, considerable strength is required; and, at the same time, great care is necessary, lest it should slip, and severely injure the cheek or face of the shooter.

*Rabbit Shooting.*—This amusement

never appeared to me as coming fairly within the class of what are generally understood as constituting field sports.

As far as relates to the natural history of this little animal, and its surprising fecundity, they are matters very well and very generally known.—See the article *RABBIT*.

In some parts of the country, rabbits form a sort of staple commodity with the occupiers of the ground; but, generally speaking, they are a nuisance to the farmer and the agriculturist, when suffered to become numerous at a distance from an established warren. But I am always much pleased to see plenty of rabbits in a fox hunting country; and I am decidedly of opinion, that under such circumstances, however numerous foxes may be, those who are anxious to preserve winged game, have little to apprehend from their depredations.

As rabbits are not able to form their burrows in strong clayey\* soils, so they are rarely found upon them. Sandy or light dry soils are the favourite resort of these animals, as, in such places, they can easily form that subterranean asylum in which they never fail to seek refuge on any emergency. But, although rabbit warrens appear like a honeycomb, from the numerous holes formed upon them, and although a solitary rabbit is seldom, if ever, found at any considerable distance from its hole, yet it is evident, that the rabbit prefers being upon the ground, rather than under it, and considers its vaulted recess merely as a place of refuge.

If undisturbed, they will sit in the hedge-rows, or in the fields, like the hare; and even the female, when about to bring forth, generally quits the regular or accustomed burrow, and forms a more superficial, but less obvious, retreat, in which to deposit her young.

It will, therefore, easily be perceived, that it is in the immediate vicinity of the warren that we are to expect rabbit shooting, (large or small as it happens to be,) as the rabbits, when disturbed, make away for their burrow, and thus present an object for the shooter. For rabbit shooting, a terrier is preferable to either pointer, setter, or spaniel:—to use a pointer or setter for the purpose, is at once to ruin

---

\* The same person who taught Slut, the black sow, to set, &c.

---

\* If they attempt to scratch the earth in such places, the clay adheres to their feet, and entirely prevents their successful progress.

him; nor, indeed, strictly speaking, ought a rabbit to be killed over either of them, under any circumstances. An obedient terrier, that will spring the rabbit without pursuing it, answers the purpose very well: his business is merely to drive the rabbits from the banks, hedge-rows, sides of pits, and other places; while the shooter must be on the alert, ready to present the moment the rabbit appears. 'This *amusement* (for I think it scarcely merits the title of *diversion*) is a very different business from shooting at winged game, or even at a hare; as, in the latter case, *deliberation* may be regarded as a perfection; in the former, the shooter cannot be *too quick*. The rabbit possesses extraordinary speed for a short distance, and, when disturbed from its seat, darts towards its hole or burrow with the utmost rapidity, and that, too, in such a jumping, jerking manner, as to render the utmost promptitude and quickness indispensably necessary, in order to attain the object in view, viz. bagging the rabbit.

The first time I tried my hand at regular rabbit shooting, I was very much mortified at the ill success of its commencement. In the early part of the day, I had been attempting to shoot on the manor of Wrightington, in Lancashire, belonging to C. Dicconson, Esq. attended by two of that gentleman's keepers—I say *attempting*, as, from the rainy and boisterous state of the weather, and it being rather late in the season, it was almost impossible to get a shot at partridges. Under such circumstances, by the advice of the keepers, I proceeded towards Mr. Dicconson's warren, for the purpose of trying my hand at rabbit shooting. I had occasionally killed rabbits which had presented themselves when I was in pursuit of other game; and, being a tolerable marksman at winged game, I entertained no idea of the disappointment I was about to experience. We proceeded to a hedge-row; and in a few minutes one of the keepers (who beat the hedge on the opposite side) vociferated the well-known signal, "*Mark!*" Out sprung a rabbit, which I very *deliberately* fired at and missed! Thus I continued for six successive discharges, when one of the keepers observed, that, unless I altered my plan, I should not be able to kill a single rabbit. "Keep your thumb on the cock, Sir, (said he,) ready to pull up, and fire as quickly as possible." I took his advice. In a few seconds, the word "*Mark!*" again prepared me for game. I had the

gun to my shoulder at the first glance of the rabbit; and the moment I could catch the sight or aim, I pulled the trigger, and over tumbled the rabbit. I killed the three following, missed the fifth, and killed five more in succession, thus bagging four couple and a half out of ten shots.

I learned from the keeper, that Mr. Dicconson was so expert at rabbit shooting, as frequently to substitute a ball for the shot, and that, too, successfully.

It is a practice with some of our modern shooters, to carry the gun cocked—a system pregnant with danger. Rabbit shooting alone seems to require such a method; but, even in this case, it is unnecessary, as rabbits can be killed with almost unerring certainty in the manner I have above described. I am not aware of a more dangerous practice than that of carrying guns cocked; no wonder if such a system produce many fatal accidents. I would abandon shooting altogether, rather than thus place my own or my friend's life in continual jeopardy.

In rabbit shooting, a ferret is sometimes employed. In this case, the mouth of the ferret is stitched up, or secured, and it is suffered to enter the burrows, from which the rabbits (if there are any) will very soon bolt, so great is their terror of this creature, and, indeed, of all the weasel tribe. In riding over from Liverpool to Chester, as I approached Bromborough Pool, I perceived, in a field on my right, a rabbit pursued by a weasel. The rabbit, though a considerable distance in advance, did not appear to exert its utmost speed. The pursuit, however, continued. The rabbit went through the hedge, and was followed by its merciless foe; but the latter, on passing the hedge, having lost sight of its victim, instantly put its nose down, and flung for the scent like a hound. The rabbit, in the mean time, had gained some distance, but slackened its pace, and ultimately sat still till the weasel approached and seized it. I instantly alighted, and, as the distance was short, I was soon at the spot. The weasel retreated; the rabbit seemed dead; but this was the effect of fear, as, after I had carried it for some distance on the road, it recovered, and ran very stoutly away.

But to return. In rabbit shooting with a ferret, the rabbit, after being bolted by the ferret, is fired at in passing from one hole to another. This amusement, however, is, in my opinion, inferior to that which is obtained by means of the terrier.

**SHORT-JOINTED.** A horse is said to be short-jointed that has a short pastern. When this joint, or the pastern, is too short, the horse is subject to have his fore-legs, from the knee to the coronet, all in a straight line.

**SHOT.** The manufacture of this article is arrived at a very great degree of perfection. Various opinions are entertained as to the most applicable sizes for the different kinds of game. Johnson, in his "Shooter's Companion," observes, for general use I prefer No. 5, as it will answer every purpose, snipe shooting excepted, for which I should use much smaller. No. 6 or 7 will be found large enough for the early part of the partridge shooting season; but I cannot agree with General Hanger, that No. 2 is decidedly preferable for all occasions, and from one end of the season to the other. Upon trial, I found that I could scarcely average three shots (or pellets) in a card (four inches by three) at the distance of thirty two yards with No. 2. With No. 5, I averaged eight; and the latter too were driven with a force more than sufficient for the purpose. Upon increasing the distance to forty one yards, I could seldom put in more than one pellet of No. 2; No. 5, at the same distance, averaged four; No. 6, averaged five.

**SHOULDER.** That joint in a horse which connects the blade bone with the extremity of the fore thigh.

The motions of the shoulders in horses, and in most quadrupeds, are more limited than in men, their chief action being forwards and backwards, wherein they are susceptible or possess a capacity of being raised higher or lower, according to their necessity. A horse's shoulders also move a little outwards and inwards, which is necessary to their going on uneven roads. They have likewise some capacity of a circular rotation, which, however, is but small; and when a horse performs any thing by such motions, it is, for the most part, more owing to art than to nature, viz. when his shoulders have been well supplied by a good horseman, that is, when the muscles and ligaments have been stretched, and rendered pliable, by a skilful management of the rider in long-continued exercise: and therefore, when a horse is brought to perform any of those easy airs, which we observe in the manege, especially when they go through their exercises in narrow circles; though the shoulders have a great share in these exercises, and some horses are much more suited to them, by the symmetry of their

shoulders, than others, yet all the joints of the neck, back, and loins, must also contribute to it more or less. The shoulder-blades of a horse lie like two shields, one on each side, which confine the actions of his shoulders very much to straight motions; whereas, in men, they are placed behind, so that they leave the actions of the shoulders and arms without that restraint. In a horse, the rib which answers in point of situation to the collar-bone is fixed, and in a great measure immoveable; but, in man, the latter is articulated with his shoulder-blade, and participates more or less in all its motions; and hence it is that a man is enabled to turn his arms in several different directions, and to perform motions for which quadrupeds have no ability.

The faults and defects of a horse's shoulders are thus described by Gibson. A horse's shoulders, he says, should be not too much loaded; for a horse that has heavy shoulders can never move well. On the other hand, one that has very thin shoulders, with a narrow chest or bosom, though he may move briskly while he keeps sound, yet such horses are generally weak; and the most easily lamed in their shoulders of all others. A narrow-chested horse turns his elbows towards his brisket, and his toes outwards; crosses his legs in travelling, and sometimes cuts himself; and this sort of horses, by their unsteadiness, are as apt to trip and stumble as the horses that are thick-shouldered, though they do not so easily come down: in the main, they are of less value; for if they happen to get lame they are fit for nothing, being weak and slender; whereas thick-shouldered horses are generally strong; and if any accident happens that renders them unfit for other uses, they will serve for a wagon or team; but a heavy-shouldered horse, at best, is neither fit for the saddle nor for a coach, nor indeed for any thing that requires expedition. But that the reader may understand what is here meant by a heavy-shouldered horse and a thick-shouldered horse, it will be necessary to observe, that some horses have their shoulders full, and yet no way loaded; and when this proceeds only from the largeness of the bones and muscles, and when these are firm, and not loose and flabby, such shoulders will be sufficiently pliable. But when the shoulders are loaded with flesh, and the breast or bosom is also fleshy, the muscles in this case are generally clogged, which being the instruments of motion, such horses

can never step out with freedom, but as if they went upon stilts. But the worst sort of all others are those where the breast projects and hangs over, so that the fore-legs are placed backwards, and appear as if they were stuck into a horse's brisket. Some horses are greatly charged with flesh, or rather may be said to be gross upon the top of their shoulders, and all over their withers, which however is more an inconvenience than any hindrance to their motion; besides that this fleshiness often abates with exercise. It may be observed, that some thick-shouldered horses have also very short thick necks. These are usually the most fleshy of all others, and are worse than those that are thick-shouldered, and at the same time, small and slender-necked; having this additional ill quality, that they are almost always heavy upon the hand.

The diseases of this part have been named by farriers shoulder-wrench, shoulder-pight, shoulder-splait, &c. Gibson says, to understand the nature of these infirmities, it will be necessary to observe, that the blade-bone of the shoulder is fixed to the body, not by articulation or jointing, but by apposition; being laid to the ribs, and fastened by the muscles, which lie under and above it, so that when a horse happens to receive a blow or strain in the shoulder, the tendons of these muscles are stretched and relaxed; and when that is violent, it is called shoulder-splait, and becomes more or less dangerous, as the horse is more or less hardy.

Every one knows that a slip, false step, or any undue position of a horse's legs, will strain and weaken the shoulder, by stretching those ligaments; and sometimes the shoulder is affected by a hurt or bruise on the withers; the reason of which may be easily enough conceived, by any one who will examine into the structure of those parts: but when the accident proves not so violent as to cause inflammation and swelling, it is not so easily discerned, whether the lameness be in the shoulder, in the foot, or any other joint. But the infirmities of the shoulders may be distinguished from those of the feet, by having a horse put to exercise: for if the lameness be in the feet, he will halt most when he is ridden; but if it be in the shoulder, the warmer he grows the less he will halt; and, if the wrench be violent, he will be apt to cast his legs outwards, forming a circle as he goes. But if none of these signs are perceivable, the surest way is to turn him short on the lame side, for that

tries the muscles the most of any thing; so that if the hurt be in the shoulder, he will set his foot on the ground hardily, and endeavour to favour his shoulder.

In the cure, a distinction ought to be made between an old injury and one that is newly received: for in a fresh strain the first intention is to apply such things as are proper to allay the heat and inflammation, and prevent a too great flux of blood to the part; whereas in an old complaint a very different course is to be observed.

Mr. John Lawrence observes, that strains in the shoulders of horses are much less frequent than in the hinder limbs. As to the symptoms, says he, there is generally a *deceptio visus*, all lame horses appearing affected in the shoulders, however sound those parts may be, which is the occasion of the perpetual blunders of grooms and farriers, whose sole rule of judgment is from appearances and custom. The only sign to be depended upon within my knowledge, is the motion of the fore-arm, or a tenderness and tumour in the parts. The muscles or ligaments of the shoulder may be relaxed, or even a dislocation may possibly, but not very probably, happen; contusion and stunting of the point of the shoulder may ensue, from running against any hard body; and lastly, notwithstanding the merriment of Osmer, a horse may be really shook in the shoulders, of which I have been too often convinced. This last is a disease of inflammation and contraction, analogous with surbating and the foot-founder, and to be removed (when curable) by rowels and running abroad. For a dislocation, swimming is generally recommended, or reduction of the joints by extension and counter-extension (the inflammation being previously allayed by relaxing applications) under the care of an able veterinary surgeon; afterwards bandage, astringents, and long rest are to be resorted to.

**SHOULDER-PEGGED.** Horses are so called when they are gourdy, stiff, and almost incapable of motion.

**SIDE-SADDLE.** See **SADDLE**, page 755.

**SIR PETER TEAZLE.** The name of the most celebrated stallion of the last half century; his blood, performances, and progeny, being reckoned inferior to none, and superior to most of those who have ever appeared upon the turf. He was foaled in 1784; bred by the Earl of Derby, got by Highflyer, dam (Papillon) by Snap, grand-dam by Regulus, who was got by the Godolphin Arabian. At

three and four years old he was the best of his time, beating every opponent, and winning stakes to a great amount. The second day of the Craven Meeting at Newmarket in 1789, when four years old, he won a subscription of 50 guineas each; beating Meteor, Pegasus, and Gunpowder; and received forfeit from Bustler, Rockingham, Poker, Patrick, Schoolboy, Harlot, and three others. In the first October meeting of the same year, he broke down, when running against Cardock, Driver, Schoolboy, and Gunpowder, with the odds in his favour; immediately after which, he was announced as a stallion for the ensuing year, at 10 guineas a mare, and half a guinea the groom. In 1794 his get began to appear. A bay filly of Mr. Clifton's won 120 guineas at Catterick, and 145 guineas at Knutsford. Another of Mr. Tarleton's won 100gs. at Preston, and 40l. 10s. at Nottingham; and the afterwards celebrated Hermione won 80gs. at Newmarket, the Oaks stakes of 50gs. (each thirty-one subscribers) at Epsom, 50l. at Lewes, and 50l. at Reading.

In 1795, nine winners appeared, amongst whom Hermione (then Mr. Durand's) won 100gs. at Epsom; the gold cup, 40gs. and 100gs. at Oxford; 45gs. at Egham, and the queen's 100gs. at Chelmsford.

In 1796, twelve winners started. Ambrosio (three years old) won 150gs. and 50l. at York; 275gs. at the same place; and the St. Leger Stakes of 25gs. each (fifteen subscribers) at Doncaster. Brass won 300gs. and 50gs. at Newmarket. A brown colt of Sir F. Standish's won 200gs. and the Prince's stakes of 500gs. at the same place. Hermione won the two king's plates at Newmarket, and 50l. at Guildford. Parisot won the Oaks stakes at Epsom, 50gs. each, forty-two subscribers.

In 1797 his reputation as a stallion continued increasing; eleven of his produce obtained 33 stakes, plates, &c. Ambrosio won the first class of the Oatland stakes of 50gs. each, (twelve subscribers) beating Stickler, Gabriel, Play or Pay, Frederick, Trumpeter, Parrot, and Cannons; 100gs. and 200gs. at Newmarket. Hermione won the third class of the Oatlands, 50gs. each, (twelve subscribers,) beating five others; and the king's plate at Newmarket, and 50l. at Epsom; the king's plate, and 60gs. at Lewes; and the king's 100gs. at Canterbury and at Warwick. Honest John, 100gs. at York, and 100gs. at Richmond. Petrina won three

fifties at Newcastle, Knutsford, and Northampton. Shepherd, two fifties at Durham. Stamford (three years old) 200gs. and 150gs. at Newmarket, 200gs. at Epsom, 280gs. at Stamford, and the gold cup at Doncaster. Welshman won 100gs. at Chester, 50l. and 50gs. at Knutsford, and a sweepstakes at Tarporley.

In 1798, Ambrosio won eight stakes and plates, amounting to 1625gs. Black George won 180gs. and 150gs. at Chester, 45gs. at Newcastle, and 50l. at Knutsford. Demon, 100gs. at Chester, and 60gs. at Tarporley, Honest John, 200gs. at York, and 134l. at Richmond. Pentacruet, 50l. at Dumfries, and 50l. at Ayr. Petrina, the gold cup at Chesterfield, and the king's 100gs. at Lincoln. Sir Harry (three years old) the Derby stakes at Epsom, 50gs. each, thirty-seven subscribers. Stamford, 233l. 15s. and the ladies' plate at York; the gold cup, and 100l. at Doncaster.

In 1799 seventeen started, who were the winners of 37 subscriptions, sweepstakes, and plates. Ambrosio won 50l. at Newmarket, 225l. at York, and 200gs. at Doncaster. Archduke (three years old) won 400gs. at Newmarket, and the Derby stakes, 50gs. each, thirty-three subscribers, at Epsom. Black George, 50gs. at Newcastle, and 70gs. at Lichfield. Expectation (three years old) 100gs. and a handicap plate at Newmarket. Fanny, 140gs. at Doncaster. Knowsley, 60gs. at Catterick; 120gs. and the stand plate at York. Lady Jane, 25gs. at Preston, two fifties at Cardiff, 50l. at Hereford, and 50l. at Abingdon. Parisot, 800gs. at Newmarket. Petrina, 50l. at Warwick, and 50l. at Shrewsbury. Polyphemus, 50l. at Shawbury, and 50l. at Northampton. Princess, 50l. at Epsom, 50l. at Brighton, and 50l. at Reading. Pushforward, 50l. at Penrith, and 50l. at Carlisle. Roxana, 100gs. at Catterick, 300gs. and 100gs. at York, and 80gs. at Beverley. Sir Harry, the Claret stakes of 1100gs. at Newmarket. Stamford, the king's 100gs. and the ladies' plate at York.

His constantly increasing reputation as a stallion produced an annual increase of winners. In 1800 fifteen of his get started, and were the winners of thirty-nine sweepstakes, subscriptions, matches, and plates; the principal of which were, Agonistes, (three years old) 140gs. at York, 220gs. at Newcastle, the produce stakes of 100gs. each at Preston, and 160gs. at Malton. Expectation (then four years old) won ten prizes, 150 guineas, 36gs.

32½gs. and 25gs. at Newmarket; 50gs. and the jockey club plate at the same place; the pavilion stakes of 25gs. each (six subscribers) at Brighton; 200gs. and 60gs. at Lewes, and the gold cup at Oxford. Fanny, the great produce sweepstakes of 100gs. each at York, twenty-two subscribers;) seven she beat, and fourteen paid half forfeit, so that she won 1400gs. in less than eight minutes. Knowsley (the Prince of Wales's) won the king's 100gs. at Guildford, Winchester, Lewes, and Lichfield, with 80gs. also at Lewes, Robin Red-breast, 50l. at Bridgenorth, 50l. at Newcastle, 50l. at Nantwich, the king's 100gs. at Warwick, and 50l. at Lichfield. Sir Harry, 200gs. and 550gs. Sir Solomon made a very conspicuous figure.

In 1801 and 1802 he seems to have attained, in his progeny, the very summit of all possible celebrity: during the former year there appeared 15 of his produce, who were the winners of 44 sweepstakes, subscriptions, and plates, of which the most eminent were Agonistes, who won 100gs. at Newcastle, the king's plate, 216l. 5s. and the ladies' plate at York; the gold cup, of 170gs. value, at Richmond; 120gs. at Malton, and the king's 100gs. at Carlisle. Haphazard, 90gs. at Catterick, 50l. at Preston, 60l. at Knutsford, 50l. at Pontefract, 100l. at Doncaster, and 50l. at Carlisle. Lancaster, 50gs. at York, two fifties and 100gs. at Morpeth. Lucan, 100gs. at Newmarket. Sir Harry, 400gs. and 50gs. at Newmarket, 235gs. at Ascot, and the king's plate at Winchester. Telegraph, 100gs. and 50l. at Newmarket, and 45gs. at Bibury.

In the year 1802, sixteen of his get were the winners of 41 prizes; of which Agonistes won 1000gs. at Newcastle. Attainment, 50l. at Newcastle, 45l. at Nantwich. Duxbury, 250gs. and 100gs. at Newmarket. Haphazard, 50gs. at Catterick, 250gs. and 268l. 15s. at York, 92l. at Richmond, the Doncaster stakes of 10gs. each (thirteen subscribers) with 20gs. added by the Corporation of Doncaster, and the king's plate of 100gs. at Carlisle. Lancaster, 50l. at Middleham, 50l. at Manchester, 150gs. at York, 50l. and 50gs. at Preston. Lethe, 1000gs. and 50l. at York, 1000gs. at Edinburgh, and 100l. at Montrose. Lucan, 50l. at Newmarket, 130gs. at Bibury, 50l. at Oxford, 50l. at Bedford, and 50l. at Newmarket. Pipylin, 150gs. at Newmarket, and 65l. 15s. at Nottingham. Ransom, 50l. at Stamford, and 50l. at Canterbury. Robin Red-breast, 100gs. at Newmarket. Sir

Simon, 50gs. and 25gs. at Goodwood: and Wilkes, 50gs. at Newmarket.

Thus the united blood of Herod, Blank, Snap, and Regulus, are proved equal, if not superior, to every other junction or cross ever introduced. Sir Peter Teazle continued in great repute as a stallion for many years afterwards.

**SIR SOLOMON.** The name of a horse of much racing reputation: he was got by Sir Peter Teazle, dam (Matron) by Florizel, who was got by Herod. Sir Solomon was bred by Earl Fitzwilliam, foaled in 1796, and started for six different three year old stakes, (in the name of Tankersley) always running in a capital form, and in a good place, but without winning once in that year. He was then purchased by Mr. Johnson, and started (1800) for the king's plate at Nottingham (with his new name) which he won easy, beating Welter, Honeycomb, and Coniac; and the next day a 50l. plate. At York he won the king's hundred, beating Applegarth, and Honeycomb. In 1801, he won five times out of the six stakes and plates he started for. He won the stand plate at York, beating those famous horses Chance, Cockboat, and Timothy; the king's plate at Newcastle, with the gold cup, and 130gs. at the same place; the gold cup at Nottingham, and 500gs. at Doncaster. In 1802 he won the gold cup, value 100gs. and 60gs. in specie, at Newcastle. A subscription of 25gs. each, nine subscribers, and 268l. 15s. at York, (beating the famous Cockfighter,) 50l. and 70gs. at Lincoln. He was afterwards purchased by Mr. Lumley Saville, and continued to cover for some seasons afterwards.

**SIT-FAST.** This proceeds generally from a warble, and is a horny tumour on a horse's hide. If it cannot be dissolved and softened by rubbing with mercurial ointment, it must be cut out, and then treated as a fresh wound.

**SKEWBALL.** A bay gelding, foaled in 1741, bred by the Earl of Godolphin; was sold to Sir Harry Harpur, Bart. and afterwards to Lord Robert Sutton Manners.

Skewball was got by Lord Godolphin's Arabian; dam, (King Pepin, Philistine, and Smirking Nan's dam) by Whitefoot, and was own sister to Bajazet's dam.

In 1747, Skewball won 40l. at St. Edmund's Bury, beating Mr. Greville's Sportley, and 2 others; 50l. at Huntingdon, beating the same Sportley, and Mr. Prentice's Water-Gruel; 50l. at Leicester,

beating Mr. Read's Grandison, and distanced 2 others; also 50*l.* at Peterborough, beating Mr. Martindale's Merry-Cupid, Mr. Bigland's Ranger, and distanced three others. In 1748, he won 50*l.* at Chester, beating Mr. Singleton's Brisk, &c. Skewball (on account of the death of Sir Harry Harpur) was sold to Lord R. S. Manners; and, in the same year, he won 50*l.* at Derby, beating, at two heats, Mr. Prentice's Wafer, Mr. Vavasour's Champion; Mr. Rogers's Moorcock, and Mr. Greville's Phoenix. In 1749, he won 50*l.* at Derby, beating Mr. Hunt's Jigg. He was sold to Mr. Elston; and in 1750, won 50*l.* at Stamford, beating, at three heats, Mr. Curzon's Mixbury; he also ran three good heats against Little Driver, at Stockbridge. In 1751, he received a 10*l.* premium at Guildford; and won the Ladies' purse of 90*gs.* at Huntingdon, beating, at two heats, Lord Gower's Little John, Mr. Vernon's Hector, by Partner, &c.

Skewball was sold to Arthur Marvin, Esq. who raced him in Ireland, where he won a match against Sir Ralph Gore's grey mare, by Victorious, four miles, for 300*gs.*; and a great number of plates and prizes.

**SKITTISH.** A horse is said to be skittish, who is considerably above himself both in spirit and condition; displaying much more of pleasure in exercise, and the enjoyment of air and conditional freedom, (from the narrow confines of a stable,) than the least tendency to habitual vice. A skittish horse will jump two or three feet at the flight of a sparrow, or upon the rumbling approach of a carriage: he is (unless weary with work) always alive with gaiety and motion, without the least intentional injury to those who ride or drive him. There are those who confound the terms, and consider a skittish and a starting horse one and the same thing; but they are by no means synonymous.

**SKYSCRAPER.** The name of a horse of much racing celebrity: he was bred by the late Duke of Bedford, and got by Highflyer out of Everlasting. In the Craven meeting, at Newmarket, 1789, when two years old, he received forfeit from three for a sweepstakes of 200*gs.* each, across the flat. The same meeting he beat Mr. Fox's Maid of all work, across the flat, for 500*gs.* The second spring meeting (then three years old) he won the Prince's stakes of 100*gs.* each, eight subscribers; the Derby stakes at Epsom, 50*gs.* each, thirty subscribers. At the same place he received 70*gs.* compromise from

the Earl of Egremont's Tag. In the first October meeting, he received 250*gs.* forfeit from Mr. Ladbroke's Magpie, two middle miles of Beacon course, for 500*gs.* half forfeit. In the second October meeting he won a sweepstakes of 100*gs.* each, from the Ditch-in, nine subscribers. The next day he won the 50*l.* plate for three year olds, beating nine others. The same week he received 122½*gs.* forfeit in a post match with Lord Derby. In the Houghton meeting he received 130*gs.* compromise from Mr. Fox's sister to Lethe, 300 guineas, half forfeit. The same week he received 130*gs.* compromise from Mr. Fox's Braggadocio, across the flat, for 300*gs.* half forfeit.

In 1790, at the first spring meeting, he won the jockey stakes of 100*gs.* each, (half forfeit,) fourteen subscribers, of which nine paid forfeit. In the same week for the Claret stakes of 200*gs.* each, half forfeit, he received from his Royal Highness the Prince of Wales's Sujah ul Dowlah, his Royal Highness the Prince's Deir Sing, Duke of Orleans' Jericho, Lord Egremont's Calomel, and Sir C. Bunbury's Glaucus. In the first October meeting he received 100*gs.* forfeit from Montezuma. In the same meeting he won half a subscription of 30*gs.* each, (seven subscribers,) beating the famous Escape, then the property of his Royal Highness the Prince of Wales.

In the first spring meeting of 1791, he won the renewed 1400 guineas, a subscription of 200*gs.* each, half forfeit; beating Pipator; fourteen having paid forfeit. In the second spring meeting he received 150*gs.* forfeit of four, for a sweepstakes of 300*gs.* each, over the Beacon. The first spring meeting, 1792, he won the King's plate at Newmarket, beating those famous horses, Coriander, Gustavus, and Toby, with the odds ten to one against him at starting. At Stockbridge he won 50*l.* beating Thalia. He won the King's plate at Winchester; walked over for a sweepstakes of 10*gs.* each, five subscribers, at Bedford; won the King's hundred in the first October meeting at Newmarket, beating Skylark; and in the second a subscription of 60*gs.* beating Skylark and Esper-sykes, with the odds against him at starting. In 1793 he started but twice, and was beat each time by the celebrated Coriander. In 1794, on the first day of the first spring meeting at Newmarket, he won a 50*l.* plate, beating Serpent and No Pretender; about which time the Duke of Bedford, beginning to reduce his racing

establishment, Skyscraper appeared no more on the turf. He covered at Woburn Abbey, in Bedfordshire. **SLOT.** The impression of a deer's foot upon the earth.

**SLEUTH HOUND.** Called, also, **SLUTH HOUND** and **SLOW HOUND.** See the article **HOUND.**

**SMELT, THE.** Derives its name from having, in the opinion of some, the scent of a violet; of others, that of a cucumber; and so strange is the disagreement respecting the smell of this fish, that the Germans distinguish it by the title of the stink-fish: the name of sparling, which it bears in Wales, Lancashire, and in the north of England, is taken from the French *Eperlan*.

This fish inhabits the seas of the northern parts of Europe; but, is never found so far south as the Mediterranean: the Seine is one of the French rivers which receive it; but whether it is found south of that there is no authority to decide. If the observations of navigators (who have generally too much to engage their attention to think much of the minutiae of Natural History) can be depended upon, smelts are taken in the Straits of Magellan, measuring twenty inches in length, and eight in circumference.

They are met with in the seas that wash our coasts, the whole year, and seldom go far from shore, except when they ascend the rivers, which they do with the tide; and in certain of which it is remarked that they appear a long time before they spawn, being taken in abundance in the Thames and Dee, in November, and two succeeding months; in other rivers not until February; and in March and April they spawn, and are very prolific; after which they all return to the salt water, and are not seen in the rivers until the next season. It has been observed that they never come in the Mersey, so long as there is any snow water in its current; and that in the spring, and beginning of summer, they will run farther up than in the decline of the year: they are also to be met with in the docks that are opened for the reception of ships. The smelt is of a very beautiful form and colour; the head is transparent, and the skin in general so thin that with a good microscope the circulation of its blood may be seen; the irides are silvery, the pupil of a full black, the under jaw is rather prominent; in the front of the upper are four large teeth; those in the sides of both are small; in the roof of the mouth are two rows, and on the tongue two others, of large teeth; the colour of the back is whitish, with a cast of green; beneath which it is varied with blue, and then succeeds a beautiful gloss of a silvery hue; the scales are small, and readily drop off; the tail is forked; the flesh is tender, and of a delicate taste. These fish vary greatly in size: the largest Mr. Pennant ever heard of was thirteen inches long, and weighed half a pound; they are often sold in the London streets under the name of dried sparlings, being split and dried, and are recommended by the gentlemen who take their gills of a morning as adding to the wine a particular relish.

The smelt is to be angled for (when the tide runs up is preferable) with a paternoster line, having five or six hooks as many inches from

each other, and baited differently. The best bait is very small fresh shrimps, (not boiled,) or the tail of a boiled one: next to these are gentles and red paste; also that of boiled shrimps, fine white bread, and a little honey, cadis, blood-worms, and they will sometimes take a bit of their own species; some crumbs of bread steeped in water should be now and then thrown in, to keep them together.

Walton mentions, that many years since, in the month of August, such vast quantities of smelts came up the Thames that women and children became anglers for them; and that in one day, between London Bridge and Greenwich, not fewer than two thousand persons were thus employed.

**SNAFFLE.** The simplest and plainest bridle-bit is so called: it consists of only a single mouth-piece, having a joint in the middle, with a check of different lengths at each extremity, and an eye annexed to receive the reins; when which are added, it is then called a snaffle (or single-reined) bridle. When snaffle-bits are made very large in the mouth for breaking colts and fillies, they are then called mouthing-bits.

**SNAP.** A brown horse, foaled in 1759, the property of Mr. Latham.

Snap was got by Mr. Shafto's Snap, his dam, (bred by Mr. Meredith) by Cade; grandam, (Dormouse dam,) by Partner, and was own sister to the dam of Molotto; also own sister to the dams of Torismond, Young Cade, Changeling, Match'em, Sweepstakes, &c. Snap's dam was own sister to Mr. Meredith's Mercury and Merryman; also to Mr. Swinburn's Cadormus.

At Ascot-heath in June, 1763, Snap won 50l. for four-year olds, 8st. 7lb. and five-year olds, 9st. 5lb. two-mile heats, beating, at three heats, the Duke of Ancaster's Proxy, by Blank, 5 years old; Mr. Vernon's Cerberus, by the Godolphin Hunter, 5 years old, and four others:—Snap won the first and third heats from Proxy, who won the second heat from Snap. At Malden in August, he won 50l. for four years old, colts 8st. 7lb. and fillies, 8st. 4lb. beating Mr. White's Lucy Cooper, by Tartar; Lord March's bay filly, by ———; Mr. Churchill's bay filly, by Young Cade; and Mr. Burlton's Romeo. At Guildford in June, 1764, he won 50l. for four-year olds, 6st. 10lb.; and five-year olds, 8st. 4lb. four-mile heats, beating Mr. Roger's Cub, by Cub, four-years old; and Mr. Wildman's Gift, by Regulus, five-years old:—at starting, 6 to 4 on Snap. At Ascot-heath in June, he won 50l. for four-year olds, 8st. 7lb. and five-year olds,

9st. 5lb.; two-mile heats, beating, at three heats, Mr. Wildman's Granby, five-years old. Mr. Vernon's Follower, 5 years old, and 2 others:—at starting, 6 to 4 on Granby, and 6 to 1 against Snap, who won the second and third heats from Granby. At Blandford in July, he won 50l. for five-year olds, 9st. 6lb.; and aged, 10st. 10lb. beating Mr. Strode's Star, 5 years old; Mr. Hilliar's Zepharus, aged; and Mr. Dee's Chalfont, aged:—he also, at the same place, won 50l. give-and-take, beating Mr. Beckford's Amelia, 5 years old; and Mr. Frenchard's Aurora, 5 years old. At Chelmsford in August, he received 20gs. no horse entering against him. At Odsey in September, he won 50l. for five-year olds, 8st. 11lb. beating Lord Orford's Ghost:—the first heat was deemed a dead one, and Ghost fell in running for the second. At Maidenhead, (same month) he won 50l. for five-year olds, 9st. 1lb. and six-years old, 9st. 9lb; beating Mr. Wilkin's Athelstone, 6 years old; and distanced, the first heat, Mr. Adams's Mercury, 6 years old. And at Odiham in October, he won 50l. weight for age and qualifications, beating, at three heats, Lord Portmore's brown Surrey, by Steady, four years old; Mr. Dawson's Slouch, 5 years old, and 4 others:—Brown Surrey won the first heat from Snap, who won the second from Brown Surrey, and the third from Slouch. At Epsom, in May, 1765, Snap won 50l. free for any horse carrying 9st.; beating Mr. Dutton's Americus, aged; and Mr. Cox's Harry Longlegs, aged:—at starting, 5 to 2 on Snap. At Ascot-heath in June, he won 50l. for six-year olds, 9st. 7lb. beating Mr. Shafto's Broomstick, by Regulus, who was drawn after the first heat:—2 to 1 on Snap. At Marlborough, (same month) he won 50l. free for any horse carrying 8st. 7lb. beating Mr. Humphrey's Hazard, aged; Mr. Strode's Tiney, aged; and Mr. Popham's

Greybeard, aged. At Winchester in July, he won 50l. for five-year olds, 9st.; six-years old, 10st. beating the Duke of Cumberland's Milksop, 5 years old. And at Odsey in September, he won 50l. for six-year olds, 8st. 10lb.; and aged, 9st. 2lb.; beating, at three heats, Mr. Quick's General, aged; and Mr. Byng's Dragon, six-years old:—General won the first heat from Snap, who won the second and third from General. At Epsom, in May, 1766, Snap won 50l. free for any horse, &c. 9st.; beating Mr. Lane's Crop, aged; Mr. Quick's General, aged; and Mr. Hale's Looby, aged:—7 to 4 on Snap. At Ascot-heath in June, Snap started for 50l. for aged horses, &c. 9st. 12lb. when he won the first heat from Mr. Quick's General, and Mr. Strode's Star; but he fell lame in running for the second heat, and was beat for that and the third heat with some difficulty: Star was third for every heat. And at Epsom in May, 1767, he won 50l. for aged horses, &c. 9st. beating, at three heats, Mr. Tyrer's Ploughboy, (who won the second heat from Snap) Mr. Quick's Dædalus, and Mr. Strode's Leopardess:—at starting, 5 to 4 on Snap. This was the only time of his starting that year, and last of his running.

Snap started only twice besides the above, viz.;—at Epsom, in 1763, when he was beat by Mr. Wildman's Granby, (the first time of his running); beating, in the same race, Lord Portmore's Starling, and 5 others; and at Swaffham in 1765, when he was beat by Lord Bolingbroke's Filch, 5 years old, to whom he allowed nearly 3st.

**SNIPES.** These birds are to be met with in every part of the world. The snipe is seen throughout the Old Continent, from the arctic regions of Siberia to the Cape of Good Hope, at which last place it is common: it also inhabits the islands of Ceylon and Japan. In America it is met with almost without exception, particularly in South Carolina, where it swarms; it is found in equal abundance in the neighbourhood of Buenos Ayres, as well as in all the low and swampy parts of South America. It is also asserted, that, in Egypt, in the fields from whence the crops of rice are just taken, snipes are so numerous, that it is not uncommon for a person to shoot a basket full in a day.

Snipes arrive in the beginning of November in Lower Egypt, and pass the whole winter there. These birds are, in winter, very usual inhabitants of all our marshy and wet grounds, where they shelter themselves in the rushes, &c. In the summer they disperse to different parts, and are found upon our highest mountains, and also in the Highlands of Scotland, as well as upon our low and wet moors: they begin to *pipe* the first week in April; many of them breed with

Snap was a true honest runner, with good speed; and there can be no doubt but if he had been in the possession of some nobleman or gentleman who could have run him in their engagements, or matched him, but that he would have proved himself equal, if not superior, to most horses of his time at Newmarket.

Snap was a stallion at Mr. Sparrow's at Sutton, near Epsom, Surrey, at 5gs. and 5s.—he was sire of Lord Farnham's Sempronius, Hippomenes, and Cul Blank; Sir J. Shelley's Fantail; Lord Abingdon's Lady Bumfidget; Lord Waltham's Blossom; Sir F. Poole's Staring Tom; Mr. Vernon's Maxim; Mr. Parker's Lottery; Mr. Adams's Master Slender; Mr. Watson's Molly Spindle, Squib, Shrimp, Beau, &c. &c.

**SNORTING.** Is a cartilaginous propulsion of sound from the nostrils of a horse, which he avails himself of at different times, to signify sensations seemingly opposite to each other. Upon being led from the light, through a gloomy passage, to a still more gloomy stable, he is frequently observed to snort either from fear or surprize; meeting or coming suddenly upon a new, strange or unnatural object, he snorts from absolute dread of injury; taken into a stable or out-house smelling musty, from foul dung and confined air, he snorts with dislike, and enters with reluctance: but snorting in the field at exercise, or in the chase with hounds, may each be considered a proof of pleasurable gratification.

## S N I P E S

us. They lay a very large egg; and the young appear ugly and shapeless; the mother never deserts them till their long bill is firm enough to enable them to procure food. When disturbed much in the breeding season, they soar to a vast height, the male making a singular bleating noise, which, in superstitious times, was called *campana cælostis*, and when they descend, they dart down most rapidly; the cock also, whilst the hen is sitting, poises himself on his wings, sometimes making a whistling, and frequently a drumming, noise; and it is uncertain whether this noise is ventriloquous, or is produced by the motion of his wings.

These birds feed on worms and insects, which they find in the moist ground, as also on snails, which last have been found whole in their stomachs: they usually have abundance of fat, which is not apt to cloy, and rarely disagrees with those that eat it: it is cooked like the woodcock, without extracting the entrails, and is every where esteemed for its delicious flavour.

The common snipe, as we have already observed, under the head snipe shooting, weighs four ounces; length, near twelve inches; breadth, about fourteen; the bill is three inches long, and rough or serrated at the edges; the head is divided lengthways by two black lines, and three of red, one of the last passing over the middle of the head, and one above each eye; between the bill and the eyes is a dusky line; chin, white; the neck is varied with brown and red; the scapulars are beautifully striped, lengthways, on one web, and barred on the other with black and yellow; the quill feathers are dusky, but the edge of the first is white, as are the tips of the secondaries; the quill feathers next the back, are barred with black and palered; breast and belly, white; tail coverts, long, almost cover the tail, and are of a reddish brown; the tail consists of fourteen feathers, black in their lower part, then crossed with a broad bar of deep orange, another narrow one of black, and the ends white or pale orange; the vent feathers, a dull yellow; the legs, pale green; and the toes entirely divided. In the Leverian Museum are some specimens of snipes with the plumage curiously variegated.

The following interesting observations respecting the snipe were made by a gentleman of Norfolk: he says "that their first coming is early in September, which is merely transitory, stopping for a day or two, or, perhaps, only for a few hours; they are then often found in large flocks, but do not lie well. At the end of October the greatest number arrive, are found more universally dispersed, and afford better amusement than earlier in the season; but immediately as the severity of winter commences, they almost entirely disappear, and return no more till March, previous to their final departure." During frost, this gentleman says, he has searched the spring ditches (where water is constantly springing) which, remaining free from ice, presented both food and shelter; but, excepting the two or three early days of the frost, found very few. The backwardness or forwardness of the spring, he says, always influences snipes, which induced this gentleman to remark the coincidence of the time of the flowering of wild plants, and that of the re-appearance of the snipes. In Feb-

## S N I P E S

ruary, a few prematurely arrive, as in 1800, when, upon the 26th, he found several; but a frost set in and again drove them back: in 1801, between the 10th and 17th, there were many snipes in the marshes, during which period, the ground was covered with snow; he looked the same marshes on the 24th, and did not find a single snipe. In March they again visit the marshes numerous, earlier or later, according to the spring's appearance: in that of 1800 they returned on the 13th; on the 26th, they were observed to be most numerous, and within a few days, most of them left us for other countries; while some few remained to rear their off-spring in this. The spring of 1801 was very forward, and several snipes this gentleman observed, on the 9th of March, on Mounhold Heath; on the 11th there were considerable numbers in the marshes, but they were wild; by the 27th many had departed. "In the vegetable kingdom, I observed (continues this gentleman) on the 25th of March, 1800, the March violet in flower; and at that time the snipes were in greatest abundance. In 1801, the violet was in flower on the 5th of March, and on the 9th and 11th the snipes were in plenty, both on the heath and in the marshes. In 1800, the pilewort began to expand its yellow flowers, under warm hedges, by the 26th of March; in 1801, it was as early as the 11th; in both which instances it coincided, even to a day, with the appearing of the greatest number of snipes," which this gentleman observed in the spring of these two years.

The haunts and food of the jack snipe, or judcock, are similar to those of the preceding; but these birds are never met with in such numbers as the common snipe: it lies very close, and will sometimes suffer itself to be almost trodden on before it will spring; its flight is seldom distant, and its motions altogether are more sluggish than those of the common snipe. It is only half as large as the latter, weighing scarcely two ounces, for which reason, in some places, they are called *half snipes*: the dimensions, however, are not exactly in the same proportion, the length of the common snipe being twelve inches; the length of the jack snipe, eight and a half. The bill is above an inch and a half long, and black; crown of the head, black, tinged with rust colour; a black streak divides the head, lengthways, from the base of the bill to the nape of the neck; over each eye a yellow streak passes to the hinder part of the head; neck varied with white, brown, and pale red; scapulars narrow, very long, brown, and margined with yellow; the rump, of a glossy blueish purple; belly and vent, white; the greater quill feathers, dusky; tail, brown, with tawny edges, and consists of twelve pointed feathers; the legs are of a cinereous green.

These birds breed in our marshes. Fermin, in his account of Surinam, says they are seen there by thousands on the sea shore; that he must be a bad marksman who does not kill sixty at once, with fine shot; and that he killed eighty-five at a single discharge; that the flesh is excellent, but the bird so small, that a man may eat twenty at a meal. But Fermin has evidently mistaken the ox bird, or purre, for the jack snipe, as they appear in numbers sufficient to admit such aggregate slaughter.

## S N I P E S

The great or solitary snipe is not common in England, but is sometimes met with, particularly on the extensive marsh called Martin Mere, in Lancashire. They are found alone, and hence the name solitary snipe has been given them.

This bird weighs eight ounces; length, sixteen inches; bill, four inches long; crown of the head, black, divided down the middle by a pale stripe; over and beneath each eye, another of the same; neck and breast, of a yellowish white, finely marked with small semicircular lines of black; belly, with cordated spots, and sides undulated with black; the upper parts of the body, very like the common snipe; quills, dusky; tail, reddish; the two middle feathers, plain; the others barred with black.

For a further elucidation of this subject, we must again have recourse to Johnson's Shooter's Companion: speaking of the snipe, the author observes, "It frequently happens, that, an opinion once generally received, however ridiculous its origin, or absurd in itself, if it be not of a nature to excite inquiry, becomes a sort of *common law*, from the circumstance of its being handed from one generation to another with implicit credit, untainted by the most remote suspicion. Thus, in those parts of the country where I have resided, the idea that the snipe rose from its bill, or, that, in rising from the ground to fly, this bird pushed itself up by its long bill, so as to be able to use its wings, was the uniform, but mistaken, belief. Indeed I should never have suspected this opinion, but from an accidental circumstance, which occurred last winter (1822) when, in shooting at a snipe, I wounded it very slightly, merely fracturing the extreme end of one of its wings: the bird came to the ground, but made many efforts to rise again, and absolutely contrived to raise itself a yard or more repeatedly. By the time I had reloaded my gun the snipe had got to a considerable distance, principally, however, by running. As I approached for the purpose of taking it up, its efforts were repeated, during which, I distinctly observed that it did not rise from its bill, but threw itself into the air in the same manner as a crow or any other bird, by springing from its feet: but in justice I ought to remark, that the circumstance was noticed by a much younger sportsman than myself, with whom I happened to be in company, and but for him, in all probability, the bird would have been pocketed, *sans ceremonie*, and the matter (trifling enough certainly) still have remained enveloped in an ignorance equal to the mistaken fancy which originally invented it. However, while I stood watching the bird's attempts to escape, I noticed another peculiarity in it:—exhausted as it soon became by its impatient efforts to fly, it then tried to get away by running; and, when we approached very near, it repeatedly spread out its little tail like a fan, and erected it after the manner of a turkey cock; at the same time, I was fully convinced, from the length of its legs when it stood erect, that it was not at all necessary for the snipe to put its bill to the ground in order to rise, had I not witnessed its repeated attempts to fly.

"When seen on the ground, the snipe is a very pretty bird; and though its bill, compared with its size, seems out of all proportion,

yet, from the manner in which it carries its head, it presents nothing of that grotesque appearance which the enormous length of its bill would induce one to expect.

“In the course of all my shooting excursions (continues the author) I never recollect observing a snipe on the ground prior to its rising, though I have shot some hundreds. I am inclined to think they are scarcely ever seen till on the wing; and this circumstance, aided by the coincidence of an enormous length of bill, has, in all probability, given rise to the supposition before mentioned.”

There is a story recorded of a gentleman of Easthampstead, in Windsor Forest, who very warmly entertained his friend with a description of “a jack snipe he had found upon the heath, which had afforded him *sport for six weeks*; and he did not at all doubt but he would serve him for sport for the remainder of the season, if he was not taken off by a frost; and what was still more convenient, he always knew where to find him.”

**SOILING.** A term denoting the feeding of cattle, under cover, on recent vegetables.

Soiling horses in the house, says Gibson, proves sometimes beneficial, and sometimes hurtful, either when a horse's case has not been rightly judged of, or when the article made use of for soiling happens to be bad of its kind. Geldings are not frequently soiled, but chiefly stallions, because it is difficult to procure good inclosures for them to run single abroad, without much charge and trouble; for two of them will seldom agree long in one place. And therefore I should never advise any one to turn stallions to grass, or soil them in the house, unless they have such complaints as absolutely to require it; for most of the disorders for which stallions are soiled may be remedied by feeding on straw for a time instead of hay, which they will dispense with much easier than geldings: for many of our geldings are apt to grow faint and weak without hay, and few of them can be brought to eat straw readily.

If a stallion happens to be lamed in such manner as to require a place where he may range at pleasure, then an orchard, or some field that is exceedingly well fenced, should be provided for him; but if he has no lameness, but some other disorder, as heat, and eruptions on his skin, that may require soiling, or if geldings or mares are to be soiled for any such complaints, care should be taken to provide such herbage for them as is young, tender, and full of sap, whether green barley, tares, clover, or any thing else the season produces: though green barley is generally preferred to all other food for this purpose;

but then it should be cut before it shoots into the ear, while it is full of sap and moisture; for afterwards it turns dry, and the stem grows tough and hard to digest. The same caution is no less necessary with respect to clover and tares, that these be young, and cut fresh once every day or oftener, otherwise they may easily do more hurt than good; for though a horse is so strong by nature, and more vigorous and active than perhaps any other creature of his size, yet his stomach and intestines are but thin, if compared with those of some other animals of the same bulk, and more easily distended, and therefore he seems to require food of easier digestion than the horned cattle. This indeed is manifest by the choice he makes for himself when at grass, and therefore when the herbage with which a horse is soiled happens to be old, though a good feeding horse will eat it for want of something better, yet I have several times known disorders to follow upon it, by this kind of aliment stopping in the intestines and obstructing them, which has been attended with great inward heat, heaviness of the eyes, reeling, loss of appetite, and other untowardly symptoms, until a plentiful discharge of dung has been procured by emollient glysters. I have seen the fæces come away in great clods, very hard, black, and fœtid, not unlike what has lain a considerable time mellowing and rotting on a dunghill, in the same manner as happens sometimes to horses that are fed with ryegrass and clover, where they have not sufficient work or exercise to digest it. I have known others, perhaps where the digestive faculty has been stronger, break

out about the neck, rump, and other parts of the body, and sometimes on the limbs, with many other signs of a surfeit, to the great surprise and disappointment of the owner. For all such herbage, when it is divested of its sap, has very soon a tendency to putrefaction, and therefore not only induces a weak blood, but obstruction in the first passages. Hence, those who would succeed well in soiling horses should be situated near to the place where it is cut, that it may be fresh, at least every morning, and leave off when it becomes old and rank, or else go on with some other herbage which is of later growth, till the horse has been sufficiently cooled and purged.

Some horses purge but little in soiling, others a great deal more than what is usual at grass; which may sometimes be owing to the goodness or badness of the herbage, to its being younger or older, fresher or staler, or perhaps sometimes to the difference of the ground on which it grows. However, this may be as often owing to the difference of constitution in horses as to any other cause; for when several horses are soiled together, we see some purge till they fall away and grow lean, some purge very gently, and others scarcely purge at all, though they are all fed alike, and with the same herbage. The same peculiarity is often observable at grass also; which only shews, that some horses are not so easily moved to purge as others, though it is probable those that purge the least stale the most plentifully, which in some cases may be equally advantageous.

When horses lose their flesh much in soiling, they should be taken off to a more solid diet, otherwise they will grow so poor and weak as to require some time afterwards before they recover their flesh. In this there is a great difference between soiling and grazing; for if horses lose their flesh never so much at grass, yet they soon grow fat after the purging, for there they have the benefit of the open air, and great choice, an advantage which horses at soil have not, but are forced to be taken off abruptly to dry food. And therefore when a horse has done soiling, he ought to be continued some time on an open diet, at least a fortnight or three weeks. A little sweet bran may at first be mixed with his oats, and his hay sprinkled with water just when it is put into the rack, and every day gentle exercise, increasing both his food and exercise by degrees. He should also be dressed gradually, and only littered

down in the night, and not to lie constantly on his litter for the first fortnight, all sudden changes from hot to cold, or from cold to hot, being hazardous; after which he may be curried and dressed as usual, and his diet increased, to render him fit for business. Indeed we find some horses so hardy, that they scarce need these precautions; yet no man can well err with reasonable care to prevent accidents, which sometimes happen where they are least expected."

Mr. John Lawrence says, in my opinion, natural grass is superior, and more likely to answer the intended purpose of stable soiling, than tares or any other herbage; from repeated trials I have found, that horses and horned cattle prefer it to all other green meat, without even excepting the so often and highly celebrated lucern.

The great bulk of the artificial grasses is an important object; but no doubt, I conceive, can be entertained of the superior quality of the natural, either green or dry. When the vast consequence of grass is considered, both in relation to quantity and quality, the neglected state of our meadows and pasture lands, in many parts of the country, may well be wondered at, and the question naturally asked, why the simple herbage should not be cultivated with the same care and assiduity as corn: I have known it repay immensely the expense of manure, of pure and good seed brought from a considerable distance, and of the most attentive culture. There cannot be a more improvident practice, whether in a public or private view, than withholding so tenaciously, old, foul, unproductive meadow from the plough; the breaking up of which would pay so abundantly in the first instance, and still more largely in the succeeding grass crops. It is obvious, nothing more is needed, in this case, than to adopt improved methods of laying down to grass.

**SOLAND GOOSE.** See GANNET, page 365.

**SOLE OF A HORSE.** That plate of horn which, encompassing the fleshy sole, covers the whole bottom of the foot. The sole ought to be thick and strong, and the shoe of a horse so set upon the hoof as not to bear upon it; for otherwise the sole would be hurt, and not only make the horse lame, but destroy the flesh that separates it from the coffin bone.

It has been the practice of some farriers to take out the sole. It is done without touching the hoof, for taking off the crust makes a hoof cast. A horse that has been

unsoled, it is said, will recover in a month's time.

'This custom of the smiths and farriers of drawing horses' soles, in order to relieve the inflammation of the part, and to promote a free perspiration, we could never perceive the least benefit accruing from; as this management leaves such a weakness and tenderness behind, that the poor creatures ever after scarce fail of labouring under an incurable lameness. Nor has *La Fosse*, though he has recommended the practice, produced a single instance of its success. In lieu thereof, of tearing the sole up by the roots, Mr. Wood substitutes the following method, viz.:—in the first place, in order to take off from the tension of the vessels, and lessen the inflammation, blood must be drawn away at the toe of the horse, and above the hoof. After which, apply the subsequent poultice, viz.:

Take Linseed boiled in water to a pulp.

Add goose-grease, tar, and cow-dung; and boil them all together to the consistence of a poultice.

Let this be put to the foot, and all round the hoof; and above the coronet apply a cold charge. Where there is no great inflammation, the addition of a little soap to the poultice will very much assist in removing any coagulation of the blood in that quarter.

When the foot is shaped like the back part of an oyster shell, and the sole higher

than the hoof, so that the whole foot is quite filled up on the lower part, it is called a crowned sole by farriers.

SORREL. See COLOUR.

SOUND or SOUNDER. A term used for a herd of wild hogs.

SOUNDNESS.—In a horse, is of such extensive meaning, and infinite importance to the sporting world, to dealers in horses, and to individual purchasers, that it is exceedingly necessary some criterion should be fixed by which its present undefined, very quibbling, and often sinister, interpretation should be more properly and more equitably understood; for want of which, more litigation was, some years ago, carried into the Courts at Westminster, for the emolument and amusement of the gentlemen of the long-robe, than any other subject whatever. The general custom between buyer and seller is precisely this: the horse is sold with or without certain conditions in respect to soundness, and this is done by what is called a warranty on the part of the seller thus: He is warranted perfectly sound, free from vice or blemish, and quiet to ride, or draw, as either or both the latter may happen to be. A horse sold without a warranty, and taken as he is, is then purchased (and the purchase abided by) with all faults, and cannot be returned under any plea whatever, unless he can be proved to have been glandered at the time of purchase, in which state no horse can be legally sold.

SOW. Although animals of the hog kind are not in much request as pointers, yet as one of those creatures was actually taught to find and set game, the circumstance merits at least a casual notice in this place. Toomer, (already noticed in this work,) actually broke a black sow to find game, and to back and stand; and if *Slut* was not so active, she was as steady, as any pointer. The sow, called *Slut*, was bred in the New Forest, and was of that kind which maintain themselves in the forest just mentioned, except when they have young, and then are fed but a few weeks; and the sow in question was given, when about three months old, to be a breeding sow, by Mr. Thomas, to Mr. Richard Toomer, both, at that time, keepers in the forest. From having no young, she was not fed, nor taken much notice of, till about eighteen months old; she was seldom observed near the Lodge, but chanced to be seen one day when Mr. Edward Toomer was there. The brothers were concerned together in breaking pointers and setters, some of their own breeding, and others which were sent to be broke, by different gentlemen; of the latter, although they would stand and back, many were so indifferent, that they would neither hunt, nor express any satisfaction when birds were killed and placed before them. The slackness in these dogs first suggested the idea, that, by the same method, any other animal

might be made to stand, and answer the same purpose as one of those ill-bred and inactive pointers. At this instant, the sow passed by, and was remarked as being extremely handsome: R. Toomer threw her a piece or two of oatmeal roll, for which she appeared grateful, and approached very near; from that time they were determined to make a *sporting pig* of her. The first step was to give her a name, and that of *Slut* (given in consequence of soiling herself in a bog) she acknowledged in the course of the day, and never afterwards forgot. Within a fortnight, she would find and point partridges and rabbits; and her training was much forwarded by the abundance of both which were near the Lodge. She daily improved, and in a few weeks would retrieve birds that had run, as well as the best pointer; nay, her nose appeared superior to that of most pointers. They hunted her principally on the moors and heaths. Slut has stood partridges, black game, pheasants, snipes, and rabbits, in the same day, but was never known to point a hare. She was seldom taken by choice, more than a mile or two from the Lodge, but has frequently joined them, when out with their pointers, and continued with them several hours. She has sometimes set a jack snipe when all the pointers had passed it: she would back the dogs when they pointed, but the dogs refused to back her until spoken to; so that she has been frequently standing in the midst of a field of pointers. In consequence of the dogs not liking to hunt when she was with them (for they dropped their sterns, and manifested symptoms of dislike or suspicion) she did not very often accompany them, except for the novelty of the thing; or when she accidentally joined them in the forest. Her pace was mostly a trot; and she was seldom known to gallop, except when called to go out shooting, in which case, she would come home off the forest at full stretch (for she was never shut up, except to prevent her being out of the sound of the whistle or call, when a party of gentlemen had appointed to see her out the next day, and which call she obeyed as readily as a dog); and she would express as much pleasure as a dog on being shewn the gun. She always testified great delight when game, dead or alive, was placed before her. She has frequently set a single partridge at forty yards distance, her nose in a direct line to the bird; after standing some considerable time, she would drop, still keeping her nose in an exact line, and would continue in that position until the game moved: if it took wing, she would come up to the place, and put her nose down two or three times; but, if a bird ran off, she would get up and go to the place, and draw slowly after it, and when the bird stopped, she would become stationary as before. The two Toomers lived about seven miles apart, at Rhinefield and Broomey Lodges; Slut has many times gone, by herself, from one lodge to the other, as if to solicit being taken out shooting. She was about five years old, when her master died, and at the auction of his pointers, &c. was included in the sale, and bought in at ten guineas. Sir H. Mildmay having expressed a wish for this animal, she was sent to Dogmersfield Park, where she remained some years. She was last in the possession of Colonel Sikes, and was then ten years old, and had become fat and slothful; but

## S P A N I E L

would set game, nevertheless, as well as before. When killed, which was at Bassilden House, Slut weighed seven hundred pounds. Being thus dishonourably slaughtered was an unworthy death for so extraordinary an animal.

SPANIEL. This name is generally applied to the springer, or small land spaniel, as the term setter is to the large land spaniel. There is a great variety of this beautiful little animal, all of which, however, are remarkable for their cheerful activity. They are not calculated for an extensive range; and are therefore very rarely used except for beating covers, in the pursuit of the pheasant or woodcock, and they give notice of their approach to the object by a sort of *whimper*, which increases to a bark as the game springs. They are affectionate and docile, and easily broken or trained: in fact, their whole system of education consists of nothing more than merely to keep them tolerably close to the sportsman; since, if they are suffered to ramble out of gun shot, the game rises at too great a distance, the object is thus defeated which they were intended to promote, and a mortification, much better felt than can be described, must inevitably ensue. Their beauty and affectionate disposition will always excite attention; but they are, after all, perhaps better calculated for coursing than the fowling-piece, as they may be usefully employed in driving a hare from a copse or thicket, while a pointer, or particularly a setter, will answer all the purposes of pheasant or woodcock shooting. However, if sporting on a grand scale, and the utmost pinnacle of perfection, are the objects to be attained, let dogs be kept for the moors or grouse alone, others for the partridge, and the pheasant and woodcock consigned to the small land spaniel or springer.

See how with emulative zeal they strive!  
Thread the loose sedge, and through the thicket drive!  
No babbling voice the bosom falsely warms,  
Or swells the panting heart with vain alarms,  
'Till all at once their choral tongues proclaim  
The secret refuge of the lurking game.  
Swift is their course, no lengthen'd warnings now  
Space to collect the scatter'd thoughts allow;  
No wary pointer shews with cautious eyes,  
Where from his russet couch the bird shall rise:  
Perhaps light running o'er the mossy ground,  
His devious steps your sanguine hopes confound;  
Or, by the tangled branches hid from sight,  
Sudden he tries his unexpected flight.  
Soon as the ready dogs their quarry spring,  
And swift he spreads his variegated wing,  
Ceas'd is their cry; with silent look they wait  
Till the loud gun decides the event of fate;  
Nor, if the shots are thrown with erring aim,  
And proudly soars away the unwounded game,  
Will the staunch train pursue him as he flies  
With useless speed, and unavailing cries.  
No open view along the encumber'd field,  
To the cool aim will time and distance yield;  
But the nice circumstance will oft demand,  
The quickest eyesight and the readiest hand;

## S P A N I E L

Swift as he rises from the thorny brake,  
With instant glance the fleeting mark to take,  
And with prompt arm the transient moment seize,  
'Mid the dim gloom of intervening trees.  
His gaudy plumage, when the male displays  
In bright luxuriance to the solar rays,  
Arrest with hasty shot his whirring speed,  
And see unblam'd the shining victim bleed;  
But when the hen to thy discerning view,  
Her sober pinion spreads of duskier hue,  
The attendant keeper's prudent warning hear,  
And spare the offspring of the future year.

PYE.

Pointers have been tried to be used in woods and covers with bells fixed upon their collars, but the contrivance does not well answer the purpose. The bell of course keeps ringing as the dog moves, and when he makes a point, and becomes motionless the ringing ceases.

The author of the Rural Sports makes the following observations on the subject under consideration:—"Spaniels for pheasant or cock shooting cannot be too strong, too short upon the legs, or have too much courage; the thickness of the covers will oppose, and sometimes almost overpower, this combination of form and spirit. Should the woods be very extensive, when steady from hares, the spaniels cannot well be too numerous; but if given to hunt hares, they disturb the pheasants, who just fly up, and perch upon the low boughs, and the ground of the covert is in vain traversed and beat for birds that are already some yards above it; in short, a spaniel that follows a hare further than whilst in view is never worth keeping. Upon no account accept or keep a spaniel which has any taint of the hound in his pedigree, although for generations back; they will be sure to hunt hare in preference to winged game, and the stock may be crossed everlastingly, may attain beauty, strength, symmetry; yet this latent spark of the harrier will never be extinguished, and they will always show their predilection for hare whenever they have an opportunity, and this generally happens when their goodness is mostly required; namely, in covers where the winged game is preserved, and there, for the most part, hares are also in the greatest plenty. A stronger instance could not well be exhibited than in the spaniels of the deceased Lord Waltham and Mr. Hoare; a road only parted the seats of these two gentlemen, and their gamekeepers frequently shot in the woods together; their dogs were equally handsome; but those of the former would drive hares the day through, and consequently sprung every thing that accidentally laid in their course; while those of the latter no more ran hares than they did sheep; they would indeed find the hares, but follow no farther than they saw them: they were always in their places, twisting around every stub with that agility, and possessed such fineness of nose, that neither woodcock nor pheasant could escape the search. Lord Waltham's spaniel bitch had originally a cross of the beagle, and although this was tried to be remedied by resorting to the best dogs, the tendency to hare could never be subdued."

These observations of the Rev. author of the Rural Sports require some little comment. Mr. Daniel's work indeed is huddled together in a strange way; it is made up of materials, which rather display the indolence, than the correct judgment or acute perception, of the compiler: much heterogenous matter is introduced for the purpose, we suppose, of increasing the bulk of these ponderous volumes, the arrangement of which exhibits the most slovenly confusion. In the course of the work, however, we are presented with about half a dozen paragraphs of what, for the sake of distinction, we will call *original remarks*, or the elucidatory observations of the compiler; and what we have quoted above are the ideas of Mr. Daniel expressed with so much confidence, and in such a manner, as clearly to shew that the author himself attaches more than ordinary importance to them. In the first place, it may be justly remarked, that the dog is the natural enemy of the hare; and that all dogs, of whatsoever kind, pursue her, and impetuously too, merely from instinct: even the pointer, so remarkable for its docility, and which will frequently set partridges the first day it is taken into the field, will nevertheless pursue a hare as eagerly as possible, if it happen to rise before him. The reason is evident:—the dog, perceiving the hare to move in the same manner as himself, cherishes the idea of being able to overtake her, and exerts his utmost speed for that purpose; nor would the pointer ever abandon the practice of chasing hares, were he not subjected by discipline to remain steady when they get up. Pointers will chase birds also; and the reason is equally evident why he so much sooner relinquishes the pursuit of feathered game, than the practice of running hares: the birds, by raising themselves into the air, make away from him in a manner that renders his efforts palpably hopeless, and indeed seems to cast a sort of ridicule upon his progressive motion:—hence we see young dogs, before they have been subjected to discipline or restraint, though they pursue birds for some distance at first, yet they very soon shorten the space, and will not pass the first hedge which takes the birds from their view, from a perfect conviction, no doubt, that their utmost efforts cannot be otherwise than completely abortive; when, however, a hare becomes the object, the dog pursues not only to the first hedge, but as soon as he loses sight of her, he puts his nose to the ground, and continues the chase by scent when he is no longer able to carry it on by sight, nor is he very easily convinced that his efforts are unavailing. For the same reason, pointers are never inclined to set hares unless taught to do so; or, at least, to set them steadily; they soon become aware of the object before them, which they are anxious to seize, and the reason why a young dog will frequently become stationary for a few seconds, on such occasions, is, for the purpose of ascertaining, by his powers of smell, the exact spot, if possible, where the hare is situated, and thus be able to seize her with unerring certainty. The pause which young pointers generally make, without any previous tuition, on their approach to partridges, arises from the same motive, viz. a desire to seize the object; and in all probability, the observation of this circumstance originated the idea of the setting dog.

## S P A N I E L

As, however, all dogs are inclined to chase hares, it consequently follows that education becomes indispensable in order to restrain this propensity; and though it may appear strange to those who have never considered the subject, yet we have no doubt that even the harrier, by judicious discipline, might be brought to *set* hares equally as steady as he manifests eagerness in the pursuit of them. A young fox hound, if left to himself, would chase the hare as eagerly as he pursues the fox, though every sportsman knows that the well trained fox hound will not look at a hare; and hence it follows, beyond all doubt, that the superiority of Mr. Hoare's spaniels arose from the superior ability and industry of his keepers; and hence also, it unquestionably follows, that the Rev. gentleman's ideas upon this matter are very crude indeed; that, in fact he has affected to write upon a subject of which he was most profoundly and most egregiously ignorant.

The interesting little dog now under consideration, is a favourite in most countries; and has occasionally been much caressed by royalty itself. The chief order of Denmark, now called the order of the Elephant, was instituted in memory of a spaniel called *Wildbrat*, which had shewed attachment to the monarch when deserted by his subjects. The motto to the order is, "*Wildbrat was faithful.*"

Charles II. was generally accompanied to the council by a favourite spaniel, and a particular strain of the spaniel breed is still distinguished by the name of this monarch. His successor, James II. manifested a similar attachment; and it is reported of him by Bishop Burnet, that being once in danger from a storm at sea, and obliged to quit the ship to save his life, he vociferated, most impatiently—"Save the dogs and Colonel Churchill!"

There is a circumstance, noticed in early English history, seems to prove that one of the landings of the Danes in England was occasioned by the sagacity and affection of a spaniel. Lodebrock, of the blood royal of Denmark, and father of Humbar and Hubba, being in a boat with his hawks and his dog, was unexpectedly driven on the coast of Norfolk by a storm, where, being discovered and suspected as a spy, he was brought to Edmund, at that time king of the East Angles. He made himself known to Edmund, who treated him with kindness, and with whom he soon became a great favourite, particularly on account of his skill and dexterity in the chase. The king's falconer became jealous of this attention, waylaid Lodebrock, murdered him, and concealed the body among some bushes. He was very soon missed at court, and the king manifested great impatience to know what was become of him; when his dog, who had staid in the wood by the corpse of his master, till famine forced him thence, came and fawned on the king, and enticed him to follow him. The body was found, and the murderer ultimately discovered. As a punishment for so atrocious a crime, he was placed alone in Lodebrock's boat, and committed to the mercy of the sea, which, it seems, bore him to the shore which Lodebrock had quitted. The boat was recognised, and the assassin, to avoid the punishment which awaited him, said that Lodebrock had been put to death by order of Ed-

mund; which exasperated the Danes so much, that they determined on the invasion of England.

The gamekeeper of the Rev. Mr. Corsellis was constantly attended by a spaniel, which he had reared; and the faithful animal would leave him neither night nor day. Wherever old Daniel appeared, Dash was to be seen; and the dog was of great service to his master in his nocturnal perambulations. The game, at that season, the dog did not regard in the least, though no spaniel was more active in this respect in the day time. But at night, if a strange foot had entered any of the covers, Dash, by a significant whine, informed his master of the circumstance; and many poachers were captured in consequence of this singular intelligence. After some years, Old Daniel was seized with a disease which produced a consumption, and ended in death. During the progress of this fatal disorder, while old Daniel was able to crawl about, Dash regularly attended him; and when at length the old man was confined to his bed, the dog took his station at the foot of it. When death relieved the old man from his sufferings, the dog refused to quit the body, but lay upon the bed by the side of it. For some time the animal would take no food; and, although, after the burial, he was taken to the hall and caressed as much as possible, yet he took every opportunity of creeping back to the room in the cottage where his old master breathed his last, where he would continue for hours; from thence he daily visited the grave, and, at the end of fourteen days, the animal died, having absolutely pined away.

**SPANISH BARRELS.** See FOWL-ING PIECE.

**SPARRING** is a ceremony practised with game cocks during the time they are in feeding (or training). When cocks are brought up from their walks, and placed in their pens, some are, of course, too full in flesh; others, as much deficient: in the judgment of equalizing these different degrees, (by reducing the weight of one, and increasing the substance of the other,) does the art of cock-feeding entirely depend. On every second or third day, during the time they are preparing for the match, each cock has a sparring with an opponent of nearly equal weight with himself; and this sham fight continues a longer or shorter time, according to the flesh, weight, and wind, of each cock so exercised. For the occasion, and that they may not injure each other, they are equally shielded with muffers upon the parts where their spurs have been sawed off; and that they may be the better inured to labour, and prepared for difficulty, the ceremony takes place on a truss or two of straw, loosely scattered, that having no firm hold for their feet, they have less power to oppose each other.

**SPASM.** Any convulsive motion, because it contracts, or pulls, the parts it affects. The term spasm hath been variously used; in the most common sense it hath signified any preternatural contraction of any particular part of the body, either without any stimulus immediately applied to the part, or which remains after its cause is removed. More properly, spasms are those preternatural contractions which are attended with considerable mobility of the system. Dr. Cullen defines spasm to be preternatural motions of the muscles, or of the muscular fibres; and under the title of spasmodic affections he includes all the diseases which consist of a preternatural state of the contraction and motion of the muscular or moving fibres in any part of the body.

**SPAVIN.** A disease on the limbs of horses, which causes them to halt; and of three kinds, viz. the blood spavin, the bog spavin, and the bone spavin.

*Blood spavin* is a swelling and dilatation of the vein that runs along the inside of the hock, forming a little soft swelling in the hollow part, and is often attended with a weakness and lameness of the hock.

The cure should be first attempted with restringents and a bandage, which will contribute greatly to strengthen all weaknesses of the joints, and frequently will remove this disorder, if early applied; but if by these means the vein is not reduced to its usual dimensions, the skin should be opened, and the vein tied, with a crooked needle and wax-thread passed underneath it, both above and below the swelling; and the turgid part suffered to digest away with the ligatures: for this purpose, the wound may be daily dressed with turpentine and honey, incorporated together.

In treating the blood spavin, Mr. Denny advises repeated blistering, and afterwards, a compress of folded linen, moistened in the following lotion, and confined by a long bandage:

Take of Sal ammoniac, four ounces;  
Acetated ceruse, two ounces;  
Vinegar, two quarts;  
Water, four quarts. Mix.

The horse, he says, should be allowed only walking exercise for three or four weeks.

*Bog spavin* is an encysted tumour on the inside of the hough, or, according to Dr. Bracken, a collection of brownish gelatinous matter contained in a bag or cyst, which he reckons to be the lubricating matter of the joint altered, the common membrane that incloses it, forming the cyst: this case he has taken pains to illustrate in a young colt of his own; where he says, when the spavin was pressed hard on the inside of the hough, there was a small tumour on the outside, which convinced him the fluid was within-side of the joint: he accordingly cut into it, discharged a large quantity of this gelatinous matter, dressed the sore with dossils dipped in oil of turpentine, putting into it, once in three or four days, a powder made of calcined vitriol, alum, and bole: by this method of dressing, the bag sloughed off and came away, and the cure was successfully completed without any visible scar.

This disorder, according to the above description, will scarcely submit to any other method, except firing, and then the cyst ought to be penetrated to make it effectual: but in all obstinate cases that have resisted the above methods, both the cure of this and the swellings called wind-galls should be attempted in this manner. If, through the pain attending the operation or dressings, the joint should swell and inflame, foment it twice a day, and

apply a poultice over the dressings till it is reduced.

*Bone spavin* is a bony excrescence, or hard swelling, growing on the inside of the hock of a horse's leg. Without entering at all into the cause of this disorder, we shall content ourselves with describing the different kinds of it, by their symptoms, and then enter on the method of cure.

A spavin that begins on the lower part of the hock, is not so dangerous as that which puts out higher, between the two round processes of the leg bone; and a spavin near the edge is not so bad as that which is more inward towards the middle, as it does not so much affect the bending of the hock. A spavin produced by a kick or a blow, is at first no true spavin, but a bruise on the bone or membrane which covers it; therefore not of that consequence as when it proceeds from a natural cause: and those that put out on colts or young horses, are not so bad as those that happen to horses in their full strength and maturity; but in very old horses they are generally incurable. The usual method of treating this disorder is, by blistering and firing, without any regard to the situation, or cause whence it proceeds. Thus, if a fullness on the fore part of the hock comes upon hard riding, or any other violence, which threatens a spavin; in that case, such cooling astringents are proper as are recommended in strains and bruises. These happening to colts and young horses, are generally superficial, and require only the milder applications; for it is better to wear them down by degrees, than to remove them at once by severe means.

Various are the prescriptions for the blistering ointment, but the following is particularly recommended by Gibson.

Take of Hog's lard, four ounces;  
Quicksilver, one ounce;  
Venice turpentine, one ounce;  
Spanish flies powdered, a dr.  
and a half;  
Corrosive sublimate, one dr.  
Oil of origanum, two drachms.

Rub the quicksilver down completely, by triture with the turpentine; then add the lard, and, lastly, the other ingredients.

The hair is to be cut from the part as close as possible, and then the ointment applied pretty thick over the skin; this should be done in the morning, and the horse kept tied up all day, without any litter, till night, when he may be untied,

mund; which exasperated the Danes so much, that they determined on the invasion of England.

The gamekeeper of the Rev. Mr. Corsellis was constantly attended by a spaniel, which he had reared; and the faithful animal would leave him neither night nor day. Wherever old Daniel appeared, Dash was to be seen; and the dog was of great service to his master in his nocturnal perambulations. *Bone spavin* is a bony excrescence, or hard swelling, growing on the inside of the hock of a horse's leg. Without entering at all into the cause of this disorder, we shall content ourselves with describing the different kinds of it, by their symptoms, and then enter on the method of cure.

A spavin that begins on the lower part of the hock, is not so dangerous as that which puts out higher, between the two round processes of the leg bone; and a spavin near the edge is not so bad as that which is more inward towards the middle, as it does not so much affect the bending of the hock. A spavin produced by a kick or a blow, is at first no true spavin, but a bruise on the bone or membrane which covers it; therefore not of that consequence as when it proceeds from a natural cause: and those that put out on colts or young horses, are not so bad as those that happen to horses in their full strength and maturity; but in very old horses they are generally incurable. The usual method of treating this disorder is, by blistering and firing, without any regard to the situation, or cause whence it proceeds. Thus, if a fullness on the fore part of the hock comes upon hard riding, or any other violence, which threatens a spavin; in that case, such cooling astringents are proper as are recommended in strains and bruises. These happening to colts and young horses, are generally superficial, and require only the milder applications; for it is better to wear them down by degrees, than to remove them at once by severe means.

Various are the prescriptions for the blistering ointment, but the following is particularly recommended by Gibson.

Take of Hog's lard, four ounces;  
Quicksilver, one ounce;  
Venice turpentine, one ounce;  
Spanish flies powdered, a dr.  
and a half;  
Corrosive sublimate, one dr.  
Oil of origanum, two drachms.

Rub the quicksilver down completely, by triture with the turpentine; then add the lard, and, lastly, the other ingredients.

The hair is to be cut from the part as close as possible, and then the ointment applied pretty thick over the skin; this should be done in the morning, and the horse kept tied up all day, without any litter, till night, when he may be untied,

in order to lie down, and a pitch, or any sticking plaister, may be laid over it, and bound on with a broad tape, or bandage, to keep all close. After the blister has done running, and the crust begins to dry and peel off, it may be applied a second time, in the same manner as before; and this second application generally takes greater effect than the first, and in colts and young horses, makes a perfect cure.

When the spavin has been of long standing, it will require to be renewed perhaps five or six times; but, after the second application, a greater distance of time must be allowed, otherwise it might leave a scar, or cause a baldness; to prevent which, once a fortnight or three weeks is perhaps enough: and it may, in this manner, be continued six or seven times, without the least blemish, and will generally be attended with success.

But the spavins that put out on older horses, or full aged horses, are apt to be more obstinate, as being seated more inward; and when they run among the sinuosities of the joint, they are, for the most part, incurable, as they then lie out of the reach of applications, and are arrived to a degree of impenetrable hardness.

The usual method in these cases is to fire directly, or to use the strongest kind of caustic blisters; and sometimes to fire, and lay the blister immediately over the part: but this way seldom succeeds, farther than putting a stop to the growth of the spavin, and is apt to leave both a blemish and stiffness behind; besides the great risk run (by applications of so severe a nature to the tendinous parts about the joints) of exciting violent inflammation, and destroying the limb. The safest and best way, therefore, is to make trial of the blistering ointment above, and to continue it according to the directions laid down, for some months, if found necessary; the horse, in the intervals, being worked moderately. The hardness will thus be dissolved by degrees, and wear away.

Where the spavin lies deep, and runs so far into the hollow of the joint that no applications can reach it, neither firing nor medicines can avail, for the reasons above mentioned. Though bold ignorant farriers have sometimes succeeded in cases of this sort (by men of judgment deemed incurable) by the application of caustics which act very forcibly, we should prefer a properly prepared cautery, made like a fleam, under the direction of a skilful

hand, which may be applied with less danger of injuring either tendons or ligaments. After the substance of the swelling has been properly penetrated by the instrument, it must be kept running by stimulating powders, or mild blistering ointment. Where the spavin lies not very deep in the joint, and the blistering methods will not succeed, the swelling may be safely fired with a thin iron forced pretty deep into the substance, and the part should be dressed as above.

**SPAYED BITCH** is a bitch upon whom an operation has been performed, by which she is deprived the power of generating a progeny. An incision being made in the flank, midway between the hip bone and the belly, the ovaries are extracted through the orifice, and separated from the parts to which they were united: these being returned, the wound is stitched up, and heals in a few days, without farther trouble or inconvenience.

**SPEAR.** The feather of a horse, called the stroke of the spear, is a mark in the neck, or near the shoulder, of some barbs, and some Turkish and Spanish horses, representing the blow or cut of a spear, in those places, with some resemblance of a scar. This feather is deemed an infallible sign of a good horse.

**SPEED** is sportingly applicable to horse, hound, or greyhound; and upon this depends (in a great degree) the estimation in which they are held. It is customary to say, such a horse has great action, or he is in possession of the gift of going.

This is, however, considered applicable only to excellent trotters and hacknies upon the road. Speed is always used in a superior sense, and intended to convey an idea of the greatest rapidity of which the animal is capable, and which enhances his value in proportion to his qualifications. In the art of training for the turf, there are ambiguities of such magnitude, that it is averred by those who have made the practical part their study, that one training groom (from judgment, experience, and observation) shall bring a horse to the post full half a distance better than another, although their speed was considered equal when placed under the racing management of their different superintendants. This is admitted so much, and so truly, an incontrovertible fact, that training grooms have their lights and shades of reputation and celebrity, in an equal degree with the most eminent artists in the universe. Jockeys also, are admitted to possess their different degrees

of excellence, and to so very great and discriminating a nicety, that when matches are lost by some lengths, and for large sums, offers are frequently made to run the match over again for the same money, or to double the stakes, provided the winning jockey is permitted to ride the losing horse. Thus, speed is not always the same, but is evidently dependent upon contingencies, which the utmost human circumspection cannot always either foresee or prevent. The increase of speed with race horses in this country, is very readily admitted to have been great during the last seventy years; and this is impartially attributed to judicious crosses.

**SPLENTS**, in horses, are hard excrescences that grow on the shank bone, and are of various shapes and sizes. Some horses are more subject to splents than others. Young horses are most liable to them, but they often wear off and disappear of themselves. Few horses put out splents after they are seven or eight years old, unless they meet with blows or accidents.

A splent that arises in the middle of the shank bone is no way dangerous; but those that arise on the back part of this bone, when they grow large, and press against the back sinew, always cause lameness or stiffness, by rubbing against it: the others, except they are situated near the joints, seldom occasion lameness.

As to the cure of splents, the best way is not to meddle with them, unless they are so large as to disfigure a horse, or are so situated as to endanger his going lame. Splents in their infancy, and on their first appearance, should be well bathed with vinegar, or old verjuice, which, by strengthening the fibres, often puts a stop to their growth: for the membrane covering the bone, and not the bone itself, is here thickened; and, in some constitutions, purging and some diuretic drinks will be a great means to remove the thickening and moisture about the limbs, which are often the forerunners of such excrescences.

Various are the remedies prescribed for this disorder; the usual way is to rub the splent with a round stick, or the handle of a hammer, and then to touch it with oil of origanum. Others lay on a pitch plaster, with a little sublimate or arsenic, to destroy the substance. Some use oil of vitriol; some, tincture of cantharides: all which methods have at times succeeded, only they are apt to leave a scar with

the loss of hair. Those applications that are of a more caustic nature, often do more hurt than good, especially when the splent is grown very hard. Mild blisters often repeated, as recommended in the case of a bone-spavin, should first be tried, as the most eligible method. These will generally succeed even beyond expectation; but if they fail, and the splent be near the knee or joint, apply the fire and blister, in the same manner as for the bone-spavin.

Splents on the back part of the shank bone are difficult to cure, by reason of the back sinews covering them: the practice is to bore the splent in several places with an iron, not very hot, and then to fire in the common way, not making the lines too deep, but very close together.

**SPORTING**. This is a term applicable generally to the diversions of the field, and under which head we shall notice, what (for want of a better term) we will denominate wholesale sporting.

Considerable wholesale slaughter is occasionally made amongst game in England; but it is trifling compared to what takes place sometimes on the Continent. Game formerly abounded in France; and the last day which the unfortunate Louis XVI. enjoyed in the field, he killed five hundred and seventy-two head of game in eight hours—this took place in the neighbourhood of Mendon.

Prior to the French Revolution, the sporting establishment at Chantilli, belonging to the Prince of Conde, was the most extensive as well as the most magnificent in Europe. There were twenty-one miles of park, and forty-eight miles of forest! The horses, when the family were at the place, were upwards of five hundred! The dogs, from sixty to eighty couple. The servants, above five hundred! The annual average quantity of game killed for a period of thirty-two years, amounted to about 30,000 head or pieces; according to a register kept for the purpose, beginning with the year 1748, and ending with the year 1779. But the list of French game is more diffuse, or at least contains a greater variety than the game list of Great Britain, and includes, exclusively of those animals which present themselves to the English sportsman, becfigue, (a small bird, like the wheat ear) oyes d'Egypte, oyes sauvage, tudelles, crapeaux, guynard, wild boars, wolves, &c. &c.

A royal party from Vienna made a sporting excursion into the Bohemian ter-

ritories in the year 1753; they commenced operations on the 29th of August, and continued their diversion for twenty days. The party consisted of twenty-three sportsmen and sportswomen; and the number of shots fired was 116,231, and the game killed 47,950 head. The Emperor fired the greatest number of shots, viz. 9794, of which 978 were in one day. S. A. R. la Princesse Charlotte was in the field every day, on one of which she fired 889 shots. The game consisted of boars, wolves, foxes, stags, roe-bucks, pheasants, partridges, &c.

In 1788, a party of ten persons at the Chateau of Prince Adam Daversperg, in Bohemia, were out five hours on the 9th and 10th of September:—The first day, 6168 shots were fired, and 876 hares, 259 pheasants, 362 partridges, besides quails, were killed. On the second day, 5904 shots were discharged, and 181 hares, 634 pheasants, and 736 partridges, were killed: in addition to these, in the evening of the second day, were picked up, 42 hares, 65 pheasants, and 103 partridges, in all, 210 head, which could not be found in the heat of action.

In Germany, during the month of September, 1797, Prince Lichtenstein, and eleven other gentlemen, killed in one day, when they were out fourteen hours, 3900 head of game.

Hence it is evident that the slaughter of game on the continent far exceeds any thing of the kind in this country. In the year 1796, the late Duke of Bedford and 6 other gentlemen killed, in one day, upon the estates of Mr. Colquhoun, at Writham, in Norfolk, 80 cock pheasants and 40 hares, besides partridges.

At Houghton, in the same county, the late Duke of Bedford and seven others, killed, in the same space, 165 hares, 42 pheasants, 5 rabbits, a couple of woodcocks, and a brace of partridges.

Many other instances might be brought forward, but, as they are of a similar complexion, they are therefore no way necessary. Numerous instances of uncommon dexterity are recorded, but as the most extraordinary (the exploits of the Toomers) have been already noticed under another head (SHOOTING) we should deem it a waste of time to introduce any thing further on the subject. However, we cannot but regret that wholesale destruction of game, which has of late years become fashionable among the higher circles in this country; and an excess of this kind appears to us (like all other ex-

cesses) attended with much less real enjoyment than might be derived from moderation.

**SPORTSMAN.** Is the appellation of a man whose partiality for the diversions of the field is universally known. The name of sportsman has ever been considered characteristic of strict honour, true courage, unbounded hospitality, and the most unsullied integrity. While, however, this may be regarded as the general characteristic of a sportsman, there are a few which merit individual notice.

The sportsman of the old school is said to be worn down, and nearly, if not altogether, obliterated: "it was the truly independent country Squire of three or four hundred a year, who plainly appeared in his drab or plush coat, with large silver buttons, and seldom without boots. His hours of leisure and relaxation were dedicated, principally, to the sports of the field, and his travels never exceeded the distance of the county town, and that only at assizes and sessions, or to attend an election. A journey to London from a remote part of the kingdom was then considered almost as great an undertaking, as voyage to the East Indies is at the present time. In the duties of life, he was every way an example to his neighbours, and every description of people who surrounded him; acting conscientiously, he conceived his presence at church could not be dispensed with, and therefore he never failed to appear. Cards he never played at, or permitted, except at Christmas; when he also exchanged his usual beverage of ale for a bowl of potent brandy punch, garnished with toast and nutmeg." This is all well enough in its way; but as there is well known to be a propensity in some to admire and prefer every thing that savours of antiquity, so we need not be surprised that a jaundiced preference is given to the old school of sporting. In fact, like every thing else, the diversions of the field have experienced a regular progressive improvement; and although in some matters they may be occasionally overstrained, yet they must be wilfully blind, or very weak sighted indeed, who do not perceive the superior beauties of modern sporting.

We have an excellent portrait of a sportsman of the old school from the pen of the Lord Chancellor Shaftesbury. But while we profess ourselves advocates for fair play, we must in justice remark that the picture we are about to introduce was not a general likeness of sportsmen of the

same period, but one of those eccentric characters who occasionally present themselves in all ages:—"In the year 1638 (says the noble author) lived Mr. Hastings, at Woodlands, in the county of Southampton; by his quality, son, brother, and uncle to the Earls of Huntingdon. He was, peradventure, an original in our age, or rather, the copy of our ancient nobility in hunting, not in warlike times. He was very low, strong, and active, with reddish flaxen hair. His clothes, which, when new, were never worth five pounds, were of green cloth. His house was perfectly old fashioned, in the midst of a large park, well stocked with deer and rabbits; many fish ponds, a great store of wood and timber, a bowling green in it, long, but narrow, full of high ridges, never having been levelled since it was ploughed; round sand bowls were used, and it had a banqueting house, like a stand, built in a tree.

Mr. Hastings kept all manner of hounds, that ran buck, fox, hare, otter, and badger; hawks, both long and short winged. He had all sorts of nets for fish; a walk in the New Forest, and the manor of Christchurch: this last supplied him with red deer, sea, and river fish; and, indeed, all his neighbour's grounds and royalties were free to him, who bestowed all his time on these sports, but what he borrowed to caress his neighbours' wives and daughters, there not being a woman in all his walks, of the degree of a yeoman's wife (and under the age of forty) but it was extremely her own fault if he was not intimately acquainted with her. This made him popular, always speaking kindly to the husband, brother, or father, and making them welcome at his mansion, where they found beef, pudding, and beer, and a house not so neatly kept as to shame him or his dirty shoes; the great hall strewed with marrow bones, full of hawks, perches, hounds, spaniels, and terriers; the upper side of the hall hung with the fox skins of this and the last year's killing, here and there a martin cat intermixed, with gamekeepers' and hunters' poles in abundance. The parlour was a large room, as properly furnished; on the hearth, paved with brick, lay some terriers, and the choicest hounds and spaniels. Seldom less than two of the great chairs had litters of kittens in them, which were not to be disturbed, he always having three or four cats attending him at dinner; and, to defend such meat as he had no mind to part with, he

always kept order with a short white stick that he kept lying by him for that purpose.

The windows, which were very large, served for places to lay his arrows, crossbows, and other such accoutrements. The corners of the room were full of the best chosen hunting and hawking poles; an oyster table at the lower end, which was in constant use twice a day all the year round, for he never failed to eat oysters before dinner and supper through all seasons. In the upper part of the room were two small tables and a desk; on the one side of the desk was the church bible, and, on the other, the book of martyrs. Upon the tables were hawks' hoods, bells, &c. Two or three old green hats with their crowns thrust in, so as to hold ten or a dozen eggs, which were of the pheasant kind of poultry; these he took much care of and fed himself. Tables, boxes, dice, and cards, were not wanting; and in the holes of the desk was a store of old used tobacco pipes. On one side of this end of the room, was the door of a closet, wherein stood the strong beer and wine, which never came thence but in single glasses, that being the rule of the house exactly observed; for he never exceeded in drinking, nor ever permitted it.

On the other side, was the door into an old chapel, not used for devotion. The pulpit, as the safest place, never wanted a cold chine of beef, venison pasty, gammon of bacon, or a great apple pie with a thick crust extremely baked. His table cost him but little, although it was well supplied. His sports furnished all but beef and mutton, except on Fridays, when he had the best of salt as well as every other fish he could get, and this was the day on which his neighbours of the first quality visited him. He never wanted a London pudding, and always sung it in with 'my pert eyes therin a.' He drank a glass or two at meals, very often syrup of gilliflower in his sack, and always a tun glass stood by him, holding a pint of small beer, and this he often stirred with rosemary. He was affable, but soon angry, calling his servants fools and cuckoldy knaves, in one of which he often spoke truth, to his own knowledge, and sometimes both of the same person. He lived to be one hundred years of age, never lost his eye sight, but always read and wrote without spectacles, and got on horseback without help; until past four score years old, he rode up to the death of a stag as well as any man in existence."

Old Draper, the Nimrod of his day, was a real sportsman, but particularly a fox hunter, to which he dedicated the whole of a long life. "In the old, but now ruinous, mansion of Berwick Hall, in the East Riding of Yorkshire, once lived the well known William Draper, Esq. who bred, fed, and hunted, the staunchest pack of fox hounds in Europe. Upon an income of only £700 per annum, he brought up, creditably, eleven sons and daughters; kept a stable of excellent hunters, a kennel of true bred fox hounds, besides a carriage, with horses suitable for my lady and her daughters. He lived in the old honest style of his country, killing every month a good ox of his own feeding, and priding himself on maintaining a substantial table, but with no foreign kickshaws. His general apparel was a long dark drab hunting coat, a belt round his waist, and a strong velvet cap on his head. In his humour, he was very facetious, always having some pleasant story, both in the field and in the hall, so that his company was much sought after by persons of good condition, and which was of great use to him in the subsequent advancement of his own children. His stables and kennels were kept in such order, that sportsmen observed them as schools for grooms and huntsmen, who were glad to come there without wages, merely to learn their business. When they had obtained proper instruction, he recommended them to other gentlemen, who wished for no better character than a recommendation from 'Squire Draper. He was always up, during the hunting season, at four in the morning, mounted on one of his nags at five o'clock, himself bringing forth his hounds, who knew every note of their old master's voice. In the field he rode with judgment, avoiding what was unnecessary, and helping his hounds when they were at fault. His daughter Di, who was equally famous at riding, used to assist him, cheering the hounds with her voice. She died at York in a good old age; and what was wonderful to many sportsmen who dared not follow her, she died with whole bones, in her bed.

After the fatigues of the day, which were generally crowned with the brushes of a brace of foxes, he entertained those who would return with him, and which was sometimes thirty miles' distance, with old English hospitality. Good old *October* was the liquor drank; and his first fox hunting toast was, '*All the brushes in*

*Christendom.*' At the age of eighty years, this gentleman died, as he chiefly lived, for he died on horseback. As he was going to give some instructions to a friend, who was rearing up a pack of fox hounds, he was seized with a fit, and, dropping from his old favourite pony, expired! There was no man, rich or poor in his neighbourhood, but what lamented his death; and the *foxes* were the only things that had occasion to be glad that 'Squire Draper was no more!"

A picture of a somewhat different colouring and more modern date, is presented in Mr. Carter, a gentleman who possessed a respectable estate near Witney, in Gloucestershire, and could boast the best hounds and horses in that part of the country. In his dress, manners, and conversation, the huntsman and whipper-in where the evident models of his imitation. Amidst the intercourse of friendship, and in the endearments of domestic life, the language of the chase was never forgotten; even his nearest relations were esteemed only in proportion to their attachment to his darling amusement: those who were anxious for his affections, had no hopes of success, but by riding themselves into them over five barred gates; in short, throughout the surrounding country, *L'ox-hunting Carter* was the epithet by which he was universally known and distinguished. When he was one day endeavouring to leap a gate of unusual height, the leg of his favourite hunter caught between the upper bars, threw him on the other side, and tumbling with all his weight upon him, fractured one of his legs in such a manner as to leave the sufferer only the dreadful alternative of amputation or death. Mr. Carter was not long in deliberating upon the choice:—recollecting that he never should be able to keep the saddle at a fox chase with a wooden leg, he swore that he came into the world with two legs, and with two he would go out of it. In this determination he persevered, and, after languishing for some time, he departed this life, as he would have ended the pursuit of a fox, with the exulting shout of the death halloo; having previously bequeathed his estates (except an annuity of two hundred pounds to his wife) to his favourite nephew, for no other reason than because whilst a boy, he used to follow him through all the dangers and delights of the chase.

A farmer of Goodleigh, in Devonshire (Mr. Henry Stebbing) who had collected

as many pads of foxes, of which he had been in at the death, as covered the stable door and door posts, was, at his own particular request, buried with a pad in each hand; and when interred in the parish church of Stoke, he was attended by all the huntsmen and whippers-in belonging to the different packs with which he had hunted, equipped in their proper hunting dress.

A passion for the chase does not, like many other inclinations, wear away with years. Sportsmen seldom give up the pursuit while they have strength sufficient to creep into the fields. The late Sir John Hill, of Hawkstone Hall, Shropshire, followed the fox hounds till within a few months of his death, and he did not depart this life till he had attained something more than ninety years of age—we believe ninety-three.

Earl Fitzwilliam, though upwards of eighty, still goes out with his own fox hounds; and the Marquis of Cleveland, nearly as old, hunts his own hounds. Many other similar instances might be produced. Hunting, in fact, is a passion which seems scarcely ever to fade or to become extinct.

**SPRAIN OR STRAIN**, in whatever part of a horse, is a distension of the muscles, and proceeds from either slips or blows, or from hard riding.

It is necessary to observe, that, in all strains, the muscular or tendinous fibres are overstretched, and sometimes ruptured or broken. To form a true idea of these disorders, let us first consider every muscle and tendon as composed of elastic fibres, which have a proper power of their own, to contract and extend themselves; and that this function has been forcibly impaired.

In all violent strains of either tendon or muscles, whatever opinion we may entertain of bathing and anointing with favourite nostrums, which often succeed in slight cases, where, perhaps, bandage alone would have done; yet it is the latter, with proper resting the relaxed fibres till they have thoroughly recovered their tone, that are the chief things to be depended on; and frequently some months are necessary for effecting the cure.

All violent strains of the ligaments, which connect the bones together, especially those of the thigh, require time, and turning out to grass, to perfect a recovery. External application can avail but little here; the parts affected lying too deep, and so surrounded with muscles, that

medicine cannot penetrate to them. The sooner, in these cases, the horse is turned out to grass, the better, as the gentle motion in the field will prevent the ligaments from thickening, and, of course, the joint itself from growing stiff; nor do we believe that firing, so commonly practised in this case, is of half the consequence as rest, and turning out for a considerable time, which, by the bye, is always advised at the time the horse is fired.

When a horse's shoulder is over-strained, he does not put out the leg as the other; but, to prevent pain, sets the sound foot hardily on the ground, to save the other; even though he be turned short on the lame side, which motion tries him the most of any. When trotted in hand, instead of pulling his leg forwards in a right line, he forms a circle with the lame leg; and when he stands in the stable, that leg is advanced before the other. In order to cure this lameness, first bleed him, and let the whole shoulder be well bathed three times a day with hot verjuice, or vinegar: but if the lameness continue without swelling or inflammation, after resting two or three days, Bartlet orders the muscles to be well rubbed for a considerable time with opodeldoc, or either of the following mixtures.

Take of Camphorated spirit of wine,  
two ounces;

Oil of turpentine, one ounce.

Mix.

This proportion will prevent the hair coming off.

Or,

Take of the best vinegar, half a pint;

Spirit of vitriol,

Camphorated spirit of wine, of each two ounces. Mix.

When the shoulder is very much swelled, it should be fomented with woollen cloths (large enough to cover the whole) wrung out of hot verjuice.

A rowel in the point of the shoulder in this case does great service, especially if the strain has been very violent, and the swelling very large: but as to boring up the shoulder with a hot iron, and afterwards inflating it, it is both a cruel and absurd treatment; and the pegging up the sound foot, or setting on a patten-shoe, to bring the lame shoulder on a stretch, is a most preposterous practice, and directly calculated to render a horse incurably lame; for it can only be necessary in cases the very opposite to this, where the muscles have been long contracted, and

we want to stretch them out. When the parts are in a state of inflammation, *i. e.* when the accident is recent, poultices, if they can be applied, are very effectual, after bathing with hot vinegar, or verjuice. These are to be preferred greatly to cold charges, which, by drying soon on the part, keep it stiff and uneasy. Let them be prepared with linseed or oatmeal, rye-flour, or bran, boiled up in vinegar, strong beer, or red wine lees, with just lard enough to prevent their growing stiff. When, by these means, the inflammation and swelling are brought down, we may bathe the part twice a-day with either of the above mixtures, opodeldoc, or camphorated spirits of wine; and roll the part three or four inches both above and below, with a strong linen roller, of about two fingers width, which will contribute not a little to the recovery, by bringing up the relaxed parts; and perhaps that strengthening is more to be depended on than the applications themselves.

In strains of the coffin-joint, that have not been discovered in time, there will occur such a stiffness in the joint, that the horse will only touch the ground with his toe, and the joint cannot be played with the hand. The only method here is repeated blistering, and then firing superficially.

For strains in the back sinew, the knee, and fetlock, Mr. Denny says "Take away three or four pints of blood from the plate vein; and, for the first three or four days, the only necessary application is a Goulard poultice, sufficiently large to cover the limb from the knee to the hoof. This may be secured by a fillet attached to the bag, and passing over the shoulder. Goulard's water may be frequently added to the poultice. Or, instead of the poultice, a flannel roller may be applied round the leg, and kept constantly moistened with the following embrocation:

Take of Crude sal ammoniac, two oz.  
Common vinegar, one pint;  
Water, two quarts;  
Extract of lead, two ounces.  
Mix them.

When the inflammation is removed, he says, the parts may be strengthened with camphorated embrocation. Walking exercise should be allowed, and increased as the animal recovers. And should any swelling remain, after the lameness is removed, the cure may be completed by applying a mild blister, and repeating it, if necessary.

Strains of the hinder extremities are,

of course, to be treated in the same manner."

SPRINGER. See SPANIEL.

SPUR is the well known weapon with which the heel of the horseman is armed to enforce his authority.

SQUARE. In the manege, is used for working in a square. The piste or tread of a volt, instead of being always circular, and traced upon a circumference round a centre, ought to be imagined as if it formed four straight equal lines laid in a square, and equally removed from the centre, or the pillar, which represents it in the middle of the manege ground; so that to work in a square, is to ride along each of these four lines, turning the hand at every corner, and so passing from one line to another.

SQUIRT. A chesnut horse, foaled in 1732, bred by William Metcalf, Esq. near Beverley, Yorkshire; and sold to the Earl of Portmore.

Squirt was got by Mr. Bartlet's Childers, out of the Snake mare that was the dam of Shock.

At Newmarket in Oct. 1737, Squirt, 8st. 7lb. beat Lord Lonsdale's Sultan, 8st. 2lb. four miles, 200gs. At Newmarket in April, 1739, at 8st. 5lb. he beat the Duke of Bridgewater's Poker, 8st. 1lb. four miles, 200gs. After which he won 40gs. at Epsom, beating Mr. Grisewood's Ladythigh; 50gs. 10st. at Stamford, beating Mr. Major's Miss Tippet; and 30l. (10st.) at Winchester, beating Mr. Grisewood's Ladythigh, and two others. In 1740, he won the give-and-take plate at Salisbury, beating Sir Robert Fagg's Pretty Sally, and Mr. Hearley's Gainsborough.

Squirt became a stallion, and when in Sir Harry Harpur's stud, was ordered to be shot, but when Miles Thistlewaite was leading him out to the dog-kennel, he was begged off by Sir Harry's groom; after which, he got Marsk, Syphon, Mr. Pratt's famous old mare, that bred Pumpkin, Maiden, Purity, &c.—Marsk was sire of Eclipse, &c. and Syphon, got Sweetbriar, Sweetwilliam, Tandem, Daisy, &c.—Squirt was sire of several good runners, though he covered few well bred mares.

STABLE, THE. In the first place it may be observed, with respect to a stable, that it should be formed or regulated according to the description of horse which it is intended to contain, since high bred or blood horses cannot endure cold like the cart horse; a circumstance for which

an obvious reason presents itself; namely, that as his coat is much thinner and finer, he is consequently much more susceptible of the chilling atmosphere, which may be said to predominate in this country. It is asserted by many (and perhaps truly) that warm stables are productive of disease; but I know from experience that, unless the atmosphere of the stable be something more than fifty degrees in winter, it will be vain to expect either a fine coat or good condition: warmth is certainly very congenial to blood horses notwithstanding all that has been urged against it by the prejudices of the old school. It is said that horses kept in a warm stable are very liable to "*catch cold*;" surely then a human being who has been sitting over a good fire in a warm comfortable room, must run a similar, if not a greater, risk. If a stable be kept very cool in winter, the horse will not derive so much benefit from his food, he will not rest so well, as if he reposed in a warm temperature; and his coat will stare. At the same time, the stable should be well ventilated, and the ventilators placed at, or as near as possible to, the top, as the foul air uniformly ascends; and when the horses are taken out for exercise, I would have the doors and windows thrown open, by which means the stable will be completely purified.

A very good method of ventilation is by tubes or funnels, one or more, according to the size of the stable, which should be let into the ceiling by a larger end of twelve or fifteen inches square, which should narrow as it ascends, so as to become about four or five inches at its summit; this should pass out at the roof of the stable, and should be covered with a raised cap, to prevent the wet from descending. This method I consider much superior to ventilators, which revolve rapidly on their own centres; as the latter occasion a considerable draught of air. Windows should be so constructed as to admit air, when necessary, but not directly upon the horse: its current should be so broken, as to disperse the air equally throughout the stable. No stable should be formed without windows, since light is essentially necessary to its inmates. If otherwise, when the horse is taken suddenly out of the stable, the light causes a painful sensation: his imperfect vision may make him stumble or start; and although the light of the stable should not be very brilliant, but rather dusky, yet it should be suf-

ficient to prevent the ill effects arising from a sudden transition from darkness to light. The ceiling of the stable should be kept in good repair, in order to prevent the dust from the hayloft from falling upon the horses, and perhaps getting into their eyes; as also to prevent the impure air, which always ascends, from lodging in the hay. But indeed, both the hay and corn would be much better by being kept out of the stable altogether till they are required for consumption. The stalls ought to be six feet wide; and, when they are less, horses should never be turned round in them, but backed out, or serious mischief may ensue. The best mode of forming the stalls is to have them something more than six feet wide, and contrived in such a way that they can be converted into loose boxes at pleasure. Some of the stalls, at least, upon this plan are highly advisable, as they will be found extremely useful in cases of sickness, as well as on other occasions.

Bars or bails are very unsightly, and are objectionable for several reasons: the horses can play with each other when so superficially separated, as well as kick; moreover, as it generally happens that one horse will eat faster than another, the slow feeder is thus deprived of his proper share of corn. Bars are seldom seen, except in stables where stage-coach horses are kept. More horses may be, in this manner, crowded into the same space, than if divided from each other by regular partitions; (which is, of course, the principal reason for using bars;) but the animals are rendered much more uncomfortable.

Some writers, in speaking of stables, hold the following language:—"The acclivity of the generality of stalls is also a very serious objection to them, for they occasion a horse to stand unequally; and an undue proportion of weight is thrown on the hinder extremities, and the appui, or bearing of both hind and fore, becomes incorrectly placed; by which the flexor tendons, or back sinews, are put on the stretch to correct this departure from the true perpendicular of the limbs; to which circumstance, there is little reason to doubt, many of the lamenesses of horses are attributable." Now, I must honestly confess, that I never saw a stable the stalls of which were calculated to produce any such effects. A gentle slope is highly to be recommended for the stalls of all stables, which, I feel well convinced, is attended with the most beneficial effects

to the general health of the horse without placing his back sinews upon any thing like an injurious stretch. I am aware that the propagation of this ill-digested notion has induced some persons to form the floor of the stalls with an inclination towards the middle of the stall, and a small grating in the centre to receive the urine, the effluvium from which, could not fail to have an injurious influence upon the health of a horse, while for a mare, such a formation would appear entirely useless. The stalls, therefore, should be made with a gentle slope, and so contrived either with gratings or gutters, or both, so as to carry the urine completely away, if possible. In fact, cleanliness, in its most extended meaning, should be observed in every stable.

In regard to allowing horses to stand on litter during the day, there is some diversity of opinion. Litter entices a horse to lie down during the day, which, when in hard or constant work, is highly desirable; but care should be taken to remove the stained litter, and, indeed, all filth, from under him. But cases are not wanting, where constant standing upon litter produces swelling in the horse's legs; and, consequently, for an animal of this description, such a practice cannot fail to be highly injurious: it therefore follows, that, in this respect, the groom must be governed by circumstances; and a little attention will enable him to adopt the correct system. Generally speaking, I am no advocate for litter remaining under the horse during the day: it is perhaps the first and most fruitful source of contraction in the feet; and is said by some to bring on this ruinous affection with more certainty than the hardest work. Horn has a natural tendency to contraction wherever heat is applied; and the feet, by being more hotly placed in litter than on the bare and moist ground, the horny hoof is, consequently, more liable to contract. I have no objection to place a little litter under the hind feet, which are not inclined to contraction; but the case is very different with the fore feet.

The rack should be placed upright in preference to the general sloping position, and less elevated than they are usually found. When the rack is placed very high, the horse's neck is almost continually on the stretch, which must have a tendency to congest the blood within the head, and perhaps to lay the foundation for disease. If we reflect upon the matter, we shall easily perceive that such a

mode is directly the reverse of the method by which nature intended the horse should receive his food; and although we have forced this highly elegant quadruped into a sort of artificial mode of life, yet, in all our treatment of him, nature should never be altogether forgotten.

A horse should not be taken into the stable while he is very warm; but should be moved about gently till he becomes cool. The legs and feet should be washed clean, and rubbed completely dry; the feet picked out: a box attached to the stable will, for such operations, be found a very convenient appendage.

*The appointments of the horse.*—In attending to these, some things are essential to the health of the horse, such as the airing of every thing belonging to him. When a horse comes in hot from a journey, his saddle must have absorbed a very considerable quantity of moisture, and consequently should be well dried and aired. A similar observation will sometimes apply to his body clothes, &c. But, in fact, it only requires a little common sense to perceive that any thing damp applied to the body of the horse can scarcely fail to be attended with unpleasant consequences. Saddles, bridles, and indeed every thing appertaining to the horse should be kept as clean as possible; and, if attended to in proper time, are much less trouble than might be hastily supposed. When a horse comes in from hunting, or from a fatiguing journey, and, indeed, generally speaking, upon all occasions, the groom should not leave him till he is thoroughly dry, clean, and rendered as comfortable as possible.

Either in the stables, or very contiguous to them, a place should always be provided for the reception of harness and other articles of the same kind; and likewise a suitable and well-secured place for a corn-bin. If the stable be small, and it is, of course, most convenient to have the corn-bin in the room above, it should be so constructed as that the proper feed may be regulated and received from a spout in the lower part of the stable. This method saves much time and trouble in going to the bin, measuring, &c. as well as in many instances much corn.

Hitherto I have had in view, stables for hunters and the superior kinds of horses; but for husbandry horses and others, a more economical mode may be adopted. The stalls, for instance, may be reduced in width to four feet and a half or five feet. The divisions between them

should be high, so that strange horses may not see each other. And where stallions are kept, or young horses required to be left loose in a stall, they should be so inclosed as to be incapable of doing mischief. For these purposes, one or more stalls may be sparred to the top, or doors provided, which may be hung to the back posts of the stable. Where this last method is followed, the stalls serve extremely well for keeping different mares and their foals separate from others.

*Stables.*—In the construction and fitting up of stables for farm horses, it is not necessary to attend so particularly to elegance as in those which are intended for the reception of horses of other descriptions. It is, perhaps, sufficient to provide them comfortable and convenient habitations: working horses should not, however be kept in such low dirty hovels as they frequently are; as nothing tends so much to the keeping of these animals in health, as their having dry, clean, and well ventilated stables. They should, therefore, be constructed in such a manner as to keep out the severe cold of winter and the intense heat of summer, and be provided with proper drains for conveying away every kind of moisture and nastiness. The number and size of the windows should be proportioned to the extent of the stable, and be so contrived as to open and shut at pleasure. When it is necessary to save expense, shutters may be adapted to, and suspended in, the windows by iron pins, on which they may be turned as occasion requires.

In the contriving of racks and mangers, regard should be had to economy and convenience. The common and too general mode of making them extend quite across the upper end of the stall, is not only a bad, but by no means a cheap, method of constructing them. Besides, in order to save trouble, servants are extremely apt to stuff racks full of hay, however large they may be; from which various bad consequences proceed, and much hay is wasted and destroyed, by being either pulled down and mixed with the litter, or trodden under the feet of the horses.

The pernicious effects resulting from the practice of suffering horses to be continually stuffing themselves with hay, are well known to those who are acquainted with the proper management of such animals, under whose directions they are never allowed to have much hay in their racks at a time. There is also another disadvantage in this plan of fitting up

stalls, especially to farmers, as it ought to be their object to preserve every thing;—the hay-seeds are totally lost, which, if good, and carefully secured, might be of great utility and value. By the racks having so much inclination outwards, the seeds are also extremely apt to fall into the horses' ears and eyes, which often produce disagreeable effects. From these considerations it would seem that racks should have a more perpendicular direction than is commonly given them, not having a space of more than fourteen or sixteen inches from the wall; the bottom should also be sparred, in order to let the seeds fall down below, whence they may be removed by a sliding shutter or small door. The same advantages may also be obtained by leaving niches in the walls for the racks, on which plan the spars will be equal with the insides of the walls. If the niches and racks be made in the middle of the stalls, two feet or two feet and a half wide, they will in most cases be sufficient; they should, however, be carried down low enough to admit of a small box or drawer being placed under them, for the reception of the hay-seeds. Racks of this sort may likewise be placed in the corners of the stalls, and be made in such a way as that one niche may serve two stalls. They may also be placed in the angles of the stalls without having any niche, and be made of a semicircular form. But in whatever way they are made, there should constantly be a division betwixt them, which is, probably, best made of deal. By this means the farmer will be able to know, with precision, what each horse eats; which cannot be done in any other way. Where the racks are put in the corners of the stalls, it may, perhaps, be more advantageous to have them straight than circular; but in whichever way they are formed, the farmer should always have a hatch fixed for each stall, as by that means a great deal of time may be saved in feeding his horses.

It is equally unnecessary in the making of the manger to have it the same width of the stall; as a box or drawer sixteen or eighteen inches long, and twelve or fourteen inches wide, will answer every purpose. It should be so contrived that it may be readily taken out and cleaned whenever it is fouled or becomes furrowed with dirt. With the fixed mangers this can never be done, however they may be daubed by the saliva issuing from the horse's mouth during the time of feeding, or the discharges

proceeding from his nostrils when labouring under colds or other more dangerous disorders.

There is another method of making stalls, which, as being cheaper and more economical, deserves to be noticed: on this plan, the stable has neither racks nor mangers; the head of the stall is boarded about three feet from the ground, having a space of about two feet from the wall, in which the hay is to be deposited, the horse pulling his hay from below, instead of drawing it from above; which is not only more natural, but prevents the waste of hay, much of which drops down and is lost when the horse eats from the rack; but, by this method, whatever falls is again received among that from which it was taken. But even on this construction it will be necessary to have the bottom sparred, within eight or ten inches of the ground, and a box, hopper, or hay-manger, and drawer, so contrived as to

receive the seeds of the hay; where there are double stalls, the boxes may be divided in the middle. Single stalls, where they can be conveniently made, should, however, always be preferred, as more safe.

All stables should be white, or lime-washed every year; the early part of summer being the time best calculated for the operation. And, in every thing relative to horses, let cleanliness be the order of the day.

**STABLE STAND.** A term used in the forest law, when a man is found at his stand in the forest, ready to shoot at deer, or else standing close by a tree with dogs ready to slip. This is one of the four evidences or presumptions, by which a man is convicted of intending to steal the king's deer, the other three being back-berond, bloody-hand, and dog-draw.

**STAG.** If we compare the stag and the bull as to shape and form, few animals are more unlike; and yet, if we examine their internal structure, we shall find a striking similitude between them. Indeed, their difference, except to a nice observer, will scarcely be perceptible. All of the deer kind want the gall bladder; their kidneys are formed differently; their spleen is also proportionably larger; their tail is shorter; and their horns, which are solid, are renewed every year. Such are the slight distinctions between two animals, one of which is amongst the swiftest, and the other, one of the most sluggish, of the brute creation.

The stag, generally speaking, is one of those innocent and peaceful animals that seems made to embellish the forest, and animate the solitudes of nature. The easy elegance of his form, the lightness of his motions, those large branches that seem made rather for the ornament of its head than its defence, the size, the strength, and the swiftness of this beautiful creature, all sufficiently rank him among the first quadrupeds, among the most noted objects of human curiosity.

The stag or hart, whose female is called a *hind*, and the young a *calf*, differs in size and in horns from the fallow deer. He is much larger, and his horns are round; whereas, in the fallow kind, they are broad and palmated. By these the animal's age is known. The first year the stag has no horns, but a horny excrescence, which is short, rough, and covered with a thin, hairy skin. The next year the horns are single and straight; the third year, they have two antlers; three, the fourth; four, the fifth; and five, the sixth: but this number is not certain, for sometimes they have more and often less. When arrived at the sixth year, the antlers do not always increase; and although the number may amount to six or seven on each side, yet the animal's age is then estimated rather from the size of the antlers, and the thickness of the branch which sustains them,

than from their variety. These horns, large as they seem, are, notwithstanding, shed every year, and new ones come in their places. The old horns are of a firm solid texture; but while young, nothing can be more soft and tender: and, the animal, as if conscious of his own imbecility at these times, instantly, upon shedding his former horns, retires from the rest of his fellows, and hides himself in solitudes and thickets, never venturing out to pasture, except by night. During this time, which most usually happens in the spring, the new horns are very painful, and have a quick sensibility of any external impression. When the old horn is fallen off, the new does not immediately appear, but the bones of the skull are seen covered only with a thin transparent periosteum or skin. After a short time, however, this skin begins to swell, and to form a soft tumour, which contains a great deal of blood, and which begins to be covered with a downy substance that presents the feel of velvet. This tumour every day buds forward from the point like the graft of a tree; and rising by degrees from the head, shoots out the antlers on either side, so that, in a few days, in proportion as the animal is in condition, the whole head is completed. The blood vessels supply the growing horns with nourishment. As they creep along the sides of the branches, the prints of them are marked over the whole surface; and the larger the blood vessels, the deeper these marks are found to be;—hence arises the inequality of the surface of the deer's horns, which are furrowed all along the sides, the impressions diminishing towards the point, where the substance is as smooth and as solid as ivory. But it ought to be observed that this substance, of which the horns are composed, begins to harden at the bottom, while the upper part remains soft, and still continues to grow; whence it appears that the horns grow differently in deer from those of sheep or cows, in which they are always seen to increase from the bottom. However, when the whole head has received its full growth, the extremities then begin to acquire their solidity; the velvet covering or bark, with its blood vessels, dries up and then begins to fall; and this the animal hastens by rubbing its antlers against every tree it meets. In this manner, the whole external surface being stripped off by degrees, at length the whole head acquires its complete hardness, expansion, and beauty.

It is said, that if a stag be castrated when its horns are fallen off, they will never grow again; and, on the contrary, if the same operation be performed when they are on, they will never fall off. If only one of his testicles be taken out, he will want the horn on that side; if one of the testicles be only tied up, he will want the horn on the opposite side.—The horns appear, indeed, to resemble a vegetable substance grafted upon the head of an animal; and they will increase, or otherwise, according to the goodness of the pasture, and the ease and security which the creature enjoys. Like a vegetable, they grow from the extremities; like a vegetable, they are for a while covered with a bark that nourishes them; like a vegetable, they have their annual production and decay; and a strong imagina-

tion might suppose, that the leafy productions on which the animal feeds, go once more to vegetate in his horns.

The stag is usually a twelvemonth old before the horns begin to appear, and then a single branch is all that is seen for the year ensuing. The old stags usually shed their horns first, which generally happens towards the latter end of February or the beginning of March. Those of the second head (namely, such as are between five and six years old) shed their horns about the middle or latter end of March; those still younger, in the month of April; and the youngest of all, not till the middle or latter end of May. The horns of the stag generally increase in thickness and in height, from the second year of its age to the eighth. In this state of perfection they continue during their vigour of life; but as the animal grows old, the horns feel the impression of age, and shrink like the rest of the body. No branch bears more than twenty or twenty-two antlers, even in its greatest state of perfection; and the number is subject to great variation. As soon as the stags have shed their horns, they separate from each other, and seek the plainer parts of the country, remote from every other animal, which they are then utterly unable to oppose. In this state of comparative imbecility they continue nearly three months before their heads have acquired their full growth and solidity. Sometime after they have completed their horns, they seek the female, to which they call with a loud tremulous note. At this time their neck is swoln; they appear bold and furious, and desperate battles uniformly ensue. When two stags contend for the female, they paw up the earth, menace each other with their horns, bellow with all their force, and striking in a desperate manner against each other, seem determined upon death or victory. This combat is continued till one of them is defeated or flies; and it often happens that the victor is obliged to fight several of these battles before he becomes undisputed master of the field.

The master stag continues to range from female to female for about three weeks; during which he appears scarcely to eat, sleep, or rest; but continues to pursue, to combat, and to enjoy. At the end of this period of madness, (for such in this animal it appears to be) the creature that was before so fat, sleek, and glossy, becomes lean, feeble, and timid.

As soon as the rutting season is over, the stags seek the company of each other and continue together in the greatest harmony (such at least is the case with those kept in parks); the males and females seek each other only in the rutting season; and scarcely at any other period are a stag and a hind seen together: the stags herd in a separate company, and the hinds do the same.

Some interesting observations on the present subject appeared in the *Annals of Sporting*, vol. vi. page 225. Speaking of Knowsley Park, the writer observes, "Some years ago, the deer in Knowsley Park did not breed well, owing to bad management, and the Earl of Derby was frequently under the necessity of purchasing stags for the purpose of hunting in Surrey; but since Mr. F. Shaw entered

the service of the noble Earl, and superintended these animals, they have been much more prolific, and the Surrey hunt is now amply supplied with stags from the park at Knowsley. In winter, especially in hard weather, deer require considerable attention, the fallow-deer in particular; and if they are not duly supplied with food, many of them will perish. From twenty to thirty stags per season are required for the hunting establishment at the Oaks, in Surrey.

“Among the stags I saw (continues the writer) were several which manifested a more than ordinary degree of familiarity with the keeper, and, upon remarking this circumstance to him, he observed, that this confidence or friendship would continue or increase until the period or season of killing the deer arrived, when these animals would shun him with the utmost possible attention. At this time, he said, the deer would not only run from his sight, but so exquisite was their sense of smell, that they would cautiously avoid his track: if they came upon it unconsciously, they would bound over it with a tremendous leap, and make off; or turn from it and fly away like lightning. Yet, if any other person had gone along, they would pass over the track without manifesting the least concern. *Apropos*, animals of the deer kind have a slit situated at the inner corner of each eye, of which, naturalists have formed an erroneous notion, and have consequently circulated incorrect accounts respecting this extraordinary provision of nature. When these animals drink (say they) ‘they plunge their noses, like some horses, very deep under water, and continue them in that situation for a considerable time; but, to obviate any inconvenience, they can open two vents, one at the inner corner of each eye, which have a communication with the nose. Here seems to be an extraordinary provision of nature, worthy of our attention; for it appears as if these creatures could not be suffocated, though both their mouths and nostrils were stopped. This curious formation of the head may be of service to beasts of chase, by affording them free respiration; and, no doubt, these additional nostrils are thrown open when they are hard run.’ To this account, which was addressed by the Rev. Mr. White, in a letter to Mr. Pennant, that gentleman thus replied:—‘I was much surprised to find in the antelope, something analogous to what you mention as so remarkable in deer. This animal has also a long slit beneath each eye, which can be opened and shut at pleasure. On holding an orange to one, the creature made the same use of those orifices as of his nostrils, applying them to the fruit, and seeming to smell it through them.’

“The information I obtained on this subject, from the intelligent keeper who accompanied me (Mr. F. Shaw) and who has had almost innumerable opportunities of observing the slits in question, during a period of fifty years, is in opposition to the doctrine just promulgated. These slits have no communication whatever with the nose, nor is it easy to ascertain for what purpose they are designed. When the animal is irritated, they are opened and distended to the utmost; they will also be found frequently to contain a mucous discharge, as if the defluxions from the eyes and head were thus carried off.

These creatures evince a most capricious disposition, and are equally remarkable for a very peculiar animal economy. A stag in Knowsley Park, a few years back, had its leg broken by accident, the lower part of which ultimately dropped off; yet the animal continued apparently in health, except that its horns presented a new appearance; they were by no means so large as usual, were almost destitute of antlers, and as much like the horns of a goat as those of a deer."

Of all the animals that are natives of this climate, there is none that has so beautiful an eye as the stag: it is sparkling, soft, and sensible. His senses of smelling and hearing are in no less perfection. When he is in the least alarmed, he lifts the head and erects the ears, standing for a few minutes as if in a listening posture. Whenever he ventures upon some unknown ground, or quits his native covering, he first stops at the skirt of the plain to examine all around; he next turns against the wind to examine by the smell, if there be any enemy approaching. If a person should happen to whistle or call out, at a distance, the stag is seen to stop short in his slow, measured pace, and gazes upon the stranger with a kind of awkward admiration: if the cunning animal perceives neither dogs nor fire arms preparing against him, he goes forward, quite unconcerned, and slowly proceeds, without offering to fly.

The stag eats slowly and is very delicate in the choice of his pasture. When he has eaten a sufficiency, he then retires to the covert of some thicket to chew the cud in security. His rumination, however, seems performed with much greater difficulty than with the cow or the sheep; as the grass is not returned from the first stomach without much straining and a kind of hiccup, which is easily perceived during the whole time it continues.

The animal's voice is much stronger, louder, and more tremulous, as he advances in age; and in the time of rut it is even terrible. The cry of the hind or female is not so loud as that of the male, and is never exerted but by apprehension for herself or her young. It need scarce be mentioned that she has no horns, or that she is more feeble and unfit for hunting than the male. The time of gestation continues between eight and nine months, and they seldom produce more than one at a time. Their usual season for bringing forth is about the month of May, or the beginning of June, during which they take care to hide their young in the most obscure thickets, from their numerous enemies, amongst the most formidable of which, may be included the stag himself.

In the present cultivated state of this country, the stag is little known in its natural wild state. The few that still remain wild are principally to be found in Devonshire and Cornwall. They are still met with in a state of unlimited freedom in some parts of Ireland, as well as in the Highlands of Scotland, for the most part in the neighbourhood of Blair Athol.

The stag, from the elegance of his form and the lightness of his motions, is, of all the deer kind, the most beautiful. His colour is generally a reddish brown, with some black about the face, and a list of the same down the hind part of the neck, and between the shoul-

ders; he grows to a large size; and one which was killed in the neighbourhood of Aberdeen, weighed three hundred and eighteen pounds, exclusive of the entrails, head, and skin; but those found in Bavaria, far exceed this bulk. Houdins, a German geographer, relates, that on the 22nd of August, 1560, a stag was hunted and taken, which weighed 625lbs. In 886, we are told, that Basilius was attacked by a vast stag; this enormous beast lifted the emperor from his horse, on one of his horns, by his belt, and bruised his inside so much as to occasion his death.

**STAG HUNTING.** By sportsmen, the stag is called, the first year, a *calf* or *hind-calf*; the second year, a *knobber*; the third, a *brock*; the fourth, a *stagg-nard*; the fifth, a *stag*; the sixth, a *hart*. The female is called a *hind*: the first year she is a *calf*; the second, a *hearse*; the third, a *hind*. This animal is said to *harbour* in the place where he resides. When he cries, he is said to *bell*; the print of the foot is called the *slot*; his tail is called the *single*; his excrements, the *fewmets*; his horns are called his *head*; when simple, the first year, they are called *broches*; the third year, *spears*; the fourth year, that part which bears the antlers, is called the *beam*; and the little impressions upon its surface, *glitters*; those which rise from the crust of the beam, are called *pearls*. The antlers, also, have distinct names: the first that branches off, is called the *antler*; the second, the *sur-antler*; all the rest which grow afterwards till you come to the top, are called *croches*. The impression of the place where the stag has lain, is called the *layer*, or *lair*. If it be in covert or a thicket, it is called his *harbour*. When a deer has passed into a thicket, leaving marks whereby his bulk may be guessed,

it is called an *entry*. When they cast their heads, they are said to *mew*. When they rub their heads against trees to bring off the peel of their horns, they are said to *fray*. When a stag, hard hunted, takes to swimming in the water, he is said to *take soil*; when he turns his head against the hounds, he is said to stand at *bay*; and when the hounds pursue upon the scent until they have unharboured the stag, they are said to *draw on the slot*.

The Highland chieftains used to hunt the stag with the utmost magnificence; they assembled some thousands of their clans, who surrounded a great tract of country, and drove the deer to the spot where the chieftains were situated, when a sort of indiscriminate slaughter commenced—not of all the deer; for, although several hundreds might be driven to a particular spot, yet, from the peculiar rush of the animals, on finding themselves in danger, a comparative few only were killed. The author of Waverley has noticed the mode of hunting deer in the Highlands of Scotland.

One of the best descriptions of the ancient manner of hart or stag hunting is the following:—

I am the hunt, which rathe and early rise,  
(My bottell filde with wine in any wise)  
Two draughts I drinke, to stay my steps withall,  
For each foote one, because I would not fall.  
Then take my hound, in liane me behind,  
The stately hart in fryth or fell to find.  
And whiles I seeke his slotte, where he has fedde,  
The sweet byrdes sing to clear my drowsie head.  
And when my hound doth straine upon good vent,  
I must confesse, the same doth me content.  
But when I have my coverts walkt about,  
And harbred fast, the hart for coming out:  
Then I returne, to make a grave report,  
Whereas I find th' assembly doth resort.  
And lowe I crouch, before the lordings all,  
Out of my horne, the fewmets let I fall;  
And other signs and tokens do I tell,  
To make them hope the hart may like them well.

Then they command that I the wine should taste,  
 So biddes mine art ; and so my throate I baste.  
 The dinner done, I go straight wayes againe,  
 Unto my markes, and shew my master plaine.  
 Then put my hound upon the view to drawe.  
 And rouze the hart out of his layre by lawe.  
 O gamesters all, a little by your leave,  
 Can you such joyes in trifling games conceive ?

This shews, in the first place, that the sportsmen were much addicted to their cups ; and that the huntsman, in this respect, copied his master ; it further shews that the latter rose at early morn to track the deer to his lair, and then, being sure of his game, returned to the sportsmen ; whom, it would appear, dined at about the same hour which it is now the custom to breakfast ; and it would further appear, that, after dinner, they prepared for the chase.

Respecting the chase of this animal, we find the following circumstance upon record. In early times, the family of the St. Clairs settled in Scotland. They were of Norman extraction, being descended from William de St. Clair, and Margaret, daughter of Richard, Duke of Normandy. One of them, for his fair deportment, was called the *seemly St. Clair*, and the family settling in Scotland during the reign of Malcom Ceanmore, obtained large grants of land in Mid Lothian. These domains were increased by the liberality of succeeding monarchs, to the descendants of the family, and comprehended the baronies of Ross-shire, Pentland, Cowsland, Cardaine, and several others. It is said a large addition was obtained from Robert Bruce, owing to the following circumstance :—The king, in following the chase upon the Pentland Hills, had often started a "*white faunch deer*," which had always escaped from his hounds ; and he asked the nobles, who were assembled around him, whether any of them had dogs which they thought might be more successful. No courtier would affirm that his hounds were fleetier than those of the king, until Sir William

St. Clair, of Rosline, unceremoniously said, he would wager his head that his two favourite dogs "*Help and Hold*," would kill the deer before she could cross the March-burn. The king instantly caught at his unwary offer, and betted the Forest of Pentland Moor against the life of Sir William St. Clair. All the dogs were tied up except a few slow hounds to rouse the deer ; while St. Clair, posting himself in the best situation for slipping his dogs, prayed devoutly to Christ, the Blessed Virgin, and St. Catherine. The deer was shortly after roused, and the hounds were slipped, St. Clair following on horseback to cheer his dogs. The hind, however, reached the middle of the brook, upon which St. Clair threw himself from his horse in despair. At this critical moment, Hold stopped her in the brook ; and Help coming up, turned her back, and killed her on St. Clair's side. The king descended from the hill, embraced Sir William St. Clair, and afterwards bestowed on him the lands of Kirkton, Loganhouse, Earncraig, &c. in free forestrie. St. Clair, in acknowledgement of St. Catherine's intercession, built the Chapel of St. Catherine in the Hopes, the chapel yard of which is still to be seen. The hill from which Robert Bruce beheld this extraordinary chase, is still called the King's Hill ; the place where St. Clair hunted, is called the Knight's Field ; and the tomb of Sir William St. Clair, is still to be seen, on which he appears sculptured in armour with a hound at his feet.

The following beautiful lines were written by Sir Walter Scott (and appear in the *Lady of the Lake*) :—The imprisoned huntsman :

My hawk is tired of perch and hood,  
 My idle greyhound loathes his food,  
 My horse is weary in his stall,  
 And I am sick of captive thrall.  
 I wish I were as I have been,  
 Hunting the hart in forests green,  
 With bended bow and blood hound free,  
 For that's the life is meet for me.

I hate to learn the ebb of time  
 From yon dull steeple's drowsy chime,

Or mark it, as the sun beams crawl,  
 Inch after inch, along the wall;  
 The lark was wont my matins ring,  
 The sable rook my vespers sing;  
 These towers, although a king's they be,  
 Have not a hall of joy for me.

No more at dawning morn I rise,  
 And sun myself in Ellen's eyes,  
 Drive the fleet deer the forest through,  
 And homeward wend with evening dew;  
 A blithesome welcome, blithely meet,  
 And lay my trophies at her feet,  
 While fled the eve on wings of glee,  
 That life is lost to love and me.

The subject of stag hunting induces us to relate an anecdote, or rather one of the most extraordinary plans that was ever practised against the life of a human being. King William III. was passionately fond of hunting, and made it a point of honour never to be outdone in any leap, however dangerous. A gentleman of the name of Cherry, who was devoted to the exiled family, regularly joined the royal hounds, put himself foremost, and took the most desperate leaps, in the hope that the king might break his neck in following him. One day, however, he accomplished one so imminently dangerous, that the king when he came to the spot shook his head and drew back.

Queen Elizabeth was much attached to stag hunting; and it is said that Queen Anne, as she was journeying to Portsmouth, came out of the great road at Lippock, and reposing herself on a bank smoothed for that purpose (which still retains the name of Queen's Bank, and is about half a mile from Wolmer Pond) there saw, with great complacency and satisfaction, the whole herd of red deer brought by the keepers along the vale before her, consisting of about five hundred head. These deer belonged to Wolmer Forest, which, by the deer stealers, were, in the course of some years after, reduced to fifty; they continued decreasing, in fact, until the time of the old Duke of Cumberland, who sent down the stag hounds and their attendants, who took, in one summer, every stag, and conveyed them in carts to Windsor. In the winter following, the hinds were also caught and conveyed away in the same manner.

As there are scarcely any wild deer to be met with in this country, there are but few establishments of stag hounds. Those belonging to the king are entitled to notice: The kennel in which the royal

hounds are kept is situate upon Ascot Heath, near the race course, about six miles from Windsor castle. At about a mile distant from the kennel is Swinley Lodge, the official residence of the master of the stag hounds. But the presence of the master of the hounds at all times in the field is not a matter of necessity, unless when his majesty hunts, and then his personal attendance is indispensable, appearing invariably with his badge of office, a pair of gold couples, which hang suspended from a hunting belt on the left side.

His late Majesty Geo. III. was frequently out with the stag hounds, and he seemed very much to enjoy the diversion. He rode tolerably well; but of course never attempted to take any extraordinary or *rasping* leaps: he was, however, a pleasant, good tempered sportsman; and his condescending affability endeared him to all those who were in the habit of attending the hounds. On the day appointed for hunting, the deer was conveyed in a cart from the paddocks of his majesty at Swinley Lodge, to the appointed spot. Ten o'clock was generally the hour of meeting; and at the distance of one third of a mile from the cart containing the deer, the hounds, attended by the huntsman and his assistants, waited the arrival of his majesty. The huntsman and his assistants (called yeomen prick-ers) were richly apparelled in short hunting jackets of scarlet and gold; part of them having French horns appropriate to the chase.

George III. was generally very punctual. In a short time after the arrival of the hounds, he was seen approaching, attended by the master of the horse and the two equerries in waiting. On these occasions, of course, the master of the hounds was in attendance ready to receive his

majesty. As soon as his majesty had exchanged his hackney for his hunter, a signal was given for the liberation of the deer, and five or ten minutes were allowed for his going away. During this interval, the strains of the horns and the music of the pack, formed a chorus by no means unpleasing to a sportsman. The anxious moment at length arrived, and the hounds were laid on the scent.

When the deer first goes off, two of the yeomen prickers accompany him in two parallel lines, right and left, so as not to lose sight of the direction he takes so long as they can keep him in view; by which means they were generally forward to assist in stopping the hounds at any point required, more particularly if they happened to get too much a-head of the horsemen; and thus afford his majesty and others an opportunity of coming up.

When his majesty (and most likely the great body of the company) was left at a considerable distance behind, the hounds were headed and stopped, to enable the slow riders to come up, and also to allow the deer time to get second wind; as there are few of these animals, bred in parks, which would stand up long before hounds without such indulgence. Thus the pursuit is continued till the deer is taken or killed; the latter, however, seldom occurs, as every effort is made to secure him for future diversion. Although chases like these form only secondary sort of sport, and are poor indeed in the estimation of a fox hunter, yet sometimes long runs occur.

In the Easter week of 1796, the sport of the three days was excellent.—The concourse of people present on the Monday on turning out the deer on Ascot Heath, was great almost beyond comparison, and the run proved destructive to several of the horses (most likely from injudicious riding). Almost as soon as the deer had been liberated, the hounds suddenly broke away, and continued the chase in such unusual style, that in the first burst of ten miles the slow going gentry formed a tail line of full four miles; upon reaching London Blackwater, in the great Western Road, the deer turned to the right, through Sandhurst and Finchampstead, till nearly reaching Wokingham town end, and suddenly turning to the left, he continued his course in a most gallant manner through the parishes of Barkham, Arbonfield, over Farley Hill, Swallowfield, Mortimer, through the river Kennet, and to Aldermaston, near New-

bury; where he was taken after a run, *it was supposed*, of nearly fifty miles.

On the following Thursday, a deer called Sir Henry Gotte was turned out (having been presented to his majesty by a Buckinghamshire knight of that name) and went off in the most gallant style imaginable. Ten minutes' law were allowed him; and as the scent was uncommonly good, the hounds ran breast high, and could only be stopped once during the first hour and a half. The deer ran over nearly the same ground as the stag which had been turned out on Monday, till he reached Wokingham, the gardens of which town he passed through, and made away over Froghall Green, through the parishes of Binfield, Warfield, the Hazes, and Shotsbrook-coverts, Braywick, and was taken at Holyport, after a chase of four hours as fine running as possible.

On Saturday in the same week, a stag, the brother to Sir Henry Gotte, was turned out near the race course, at eleven o'clock; and facing the open country, went away in a style that seemed to bid defiance to his pursuers. After a circle of some few miles upon the heath and by Sunning Hill Park, he passed Sunning Hill Wells, Brummel Hut, and through Patnell's Warren, where he turned to the left, and reached the bridge at Virginia Water; here he waited till the hounds came nearly up to him, when surveying the approach of the field for a few seconds, he broke away and took the whole of the swampy country, and over the large fences to Thorpe Green; leaving Chertsey to the right, he passed through the meadows and crossed the Thames, continuing his course over the fields to Staines. Here he amused the inhabitants in their gardens and orchards, where he and the hounds were repeatedly together and his escape from destruction appeared almost impossible; but by clearing some most surprising leaps, he once more broke away, crossed the western turnpike road, and again led the chase in a very gallant style. Crossing the intervening inclosures to Wyradsbury, and nearly reaching Colnbrook, he made away to the right, and was taken near the seat of Sir W. Gibbons, at Stanwell, after a fine run of two hours and a half.

The royal stag hounds are still kept up in the same style of splendour and magnificence (and indeed a pack of harriers has been added to the hunting establishment), though his late majesty, Geo. IV.

seldom, we believe, if ever, attended the meetings; nor indeed does any part of the royal family appear to have imbibed the passion for hunting, which distinguished George III.

The Earl of Derby supported an extensive stag hunting establishment, which, during the hunting season, continued at the Oaks in Surrey; the rest of the year, the horses, hounds, &c. were at Knowsley, near Liverpool. The writer saw the stag hounds belonging to this nobleman, in the year 1824. These hounds did not appear so large as the royal hounds; they were, in fact, fox hounds in appearance, narrow nosed fleet animals, evidently possessing more than ordinary speed. There was one bitch in particular to which the huntsman drew our attention, and exultingly remarked that she would run four miles in less time than a greyhound! as, however, no trial had taken place, to demonstrate the truth of this position, we are free to confess that the huntsman's assertions did not exactly convince us. There were about thirty beautiful hunters in the stables; and the establishment altogether was on a scale of princely splendour.

There are, we believe, several other stag hunting establishments; but of minor consideration. In Devonshire, up to the year 1824, stag hounds, latterly under the direction of Mr. Lucas, were kept for the purpose of hunting the wild deer which still continued to exist in a state of unlimited freedom in that country; the establishment was, however, broken up in 1824; the wild deer have most likely disappeared ere this; and consequently no similar establishment is likely again to exist in this country.

It is upon the continent we are to look for stag hunting; but the system of the chase is different, and not exactly in unison with the feelings of an Englishman on the subject.

In September, 1686, (during the rutting season) as Frederick William, Elector of Brandenburg, and his Electress Dorothea, were hunting after dinner, in an open chair, at Gotze, about half a mile from Custrim, on the Oder, they saw, about one hundred paces off, a very stately stag, standing with his head pointing from them, but his left side presented towards the left side of the chair. Her most serene Highness taking aim, shot him with a leaden bullet, whereupon he moved off slowly to the distance of three or four hundred paces, losing a great quantity of

blood in his way, and tottering from weakness: he took refuge in a ditch, where M. Consart, by the help of his spaniel, found him in a standing position; and, at thirty paces distant, by the Elector's order, lodged another ball in the back part of his head; and, finding him still to keep his legs, advanced six paces nearer, and lodged a third under his left ear, when the deer instantly dropped, and lay without motion. In this condition, Conrad, a forester, and Frobenius, the Elector's master of the horse, drew him out of the ditch, and brought him near the chair, which was now come up. The Elector commanded Frobenius and Conrad to look for the wound the Electress had first given him, and they found the ball had entered close by the upper end of the bone of the left fore leg, just under the shoulder blade; they traced it with their fingers into the cavity of the breast, on towards the right side.

The forester, at this time, was sent to obtain a cart from some rustics in the neighbourhood, but it did not arrive in less than three quarters of an hour, during which time, the stag continued lying on the ground, to all appearance, lifeless. The countrymen, who came with the cart, turned him from one side upon his belly, and, laying hold of his horns, lifted his head into the cart, when, just as they were upon the point of raising the body, the stag jumped upon his feet, sprang away from them, and to the amazement and consternation of every one present, traversed the country with incredible swiftness. They then pursued him near two miles towards the Oder with hounds, which, coming up with him, stopped his progress; the forester coming up, shot him in the hinder part of the back; notwithstanding which, he made an effort towards a further escape, but was at last pulled down and killed by the dogs: he was brought to the Elector's lodge at Gotze, where the hunters opened the carcase, and, to their great astonishment, found the heart entirely perforated (the ball having passed quite through), which, as a most surprising circumstance, they represented to their most serene highnesses, who gave directions that it should be carefully examined by their physicians, Doctors Willich and March. These gentlemen reported that the ball had penetrated the posterior part of the heart, and passed through the middle of the right, a portion of the left ventricle, and made its exit through the anterior part of the heart,

under the right auricle ; the wound being large enough to admit a finger, and that the fleshy fibres of the surrounding parts were considerably lacerated and contused.

Some years ago, a stag was turned out of Whinfield Park, and hunted by the hounds of the Earl of Thanet, till, by fatigue, the whole pack were thrown out, except two staunch hounds, which continued the pursuit through the greater part of the day. The stag returned to the park, whence he had started, and, as his last effort, leaped the wall, and expired immediately. One of the hounds brought the scent up to the wall, but was so exhausted that he died on the spot; and the other hound was found dead at a short distance behind him. The length of the chase could not be exactly ascertained; but, as they were seen at Red Kirks, near Annan, in Scotland, distant by the post road about forty-six miles, it was supposed that the run could not have been less than seventy or eighty miles. In commemoration of this fact, the horns of the stag, which were the largest of any seen in that part of the country, were placed on a tree of a most enormous size in the park, and afterwards called the *hart-horn tree*. The horns have since been removed, and are now at Julian's Bower, in the same county.

In early times, when the king lost a stag, open proclamation was made in all towns and villages, near where the deer was supposed to remain, that no person should kill, hunt, or chase him, that he might safely return to the forest again, and the foresters were ordered to harbour the said hart, and by degrees bring him back to the forest; and that deer was ever after called a *hart royal proclaimed*. Some years since, an old record remained in Nottingham Castle, stating, that in 1194, Richard I. chased a stag from Sherwood Forest to Barnsdale, in Yorkshire, and there lost him. He made proclamation at Tun Hill, in Yorkshire, and divers other places in the neighbourhood of Barnsdale, that no person should chase, kill, or hunt, the said deer, that he might return to his lair in the forest of Sherwood.

The stag is an animal of great courage, as was proved by the attempt made at the instance of the late Duke of Cumberland, where a stag was inclosed in an area with a hunting tiger. It occur-

red in Ascot Race week, and this novelty attracted an additional concourse of people. On a lawn by the road side, a space was fenced in with very strong toiling fifteen feet high, into which an old stag was turned, and shortly after a hunting tiger was led in hood-winked, by two blacks that had the care of him, and his eyes and himself at once set at liberty. The instant he saw the stag, he crouched on his belly after the manner of a cat, watching an opportunity to seize his antagonist. The stag presented his brow antlers, and warily turned as he perceived the tiger creeping to get into his rear. Thus the two animals continued, the tiger endeavouring to turn the enemy's flank, and the stag equally cautious to face him; till the Duke becoming impatient, asked if by irritating the tiger, the combat could not be produced. He was told the attempt would be dangerous; but he ordered it, nevertheless, to be made: the keepers approached the tiger and did as they were ordered; when the enraged animal, instead of attacking the deer, made a furious spring and cleared the toiling that inclosed him. Great indeed was the confusion amongst the multitude, but the tiger, without molesting any one, crossed the road, and, rushing into the opposite wood, seized on a fallow deer, a herd of which happened to be near the scene of action. His keepers, after some hesitation, ventured to approach the tiger; and after cutting the deer's throat, separated the haunch, on which the animal had seized, and which he continued to hold, hood-winked him, and led him away with the venison in his mouth.

The stag was formerly used on the the continent as an instrument for punishing offenders. In the sixteenth century, a man was seen to pass through the neighbourhood of Friedberg fastened to the back of a stag: he was distinctly heard to cry for assistance, saying he had been three days in that horrid situation, the stag having brought him all the way from Saxony. Some time after, the man and the stag were both found, almost torn to pieces, near the city of Solms.

We shall close the present subject with an animated poetical description of the chase of the stag, applicable to the period when stags were found in a state of nature:—

The stag, too, singled from the herd, where long  
He rang'd the branching monarch of the shades,

Before the tempest drives. At first in speed  
 He, sprightly, puts his faith; and, rous'd by fear,  
 Gives all his swift aerial soul to flight.  
 Against the breeze he darts, that way the more  
 To leave the lessening murderous cry behind.  
 Deception short! though fleetier than the winds  
 Blown o'er the keen-air'd mountains by the north,  
 He bursts the thickets, glances through the glades,  
 And plunges deep into the wildest wood.  
 If slow, yet sure, adhesive to the track,  
 Hot streaming, up behind him come again  
 Th' exulting pack, and from the shady depth  
 Expel him, circling through his every shift.  
 He sweeps the forest oft, and, sobbing, sees  
 The glades mild opening to the golden day;  
 Where, in fierce contest, with his butting friends  
 He wont to struggle, or his loves enjoy.  
 Oft in the full descending flood he tries  
 To lose the scent, and lave his burning sides;  
 Oft seeks the herd: the watchful herd, alarm'd,  
 With selfish care, avoid a brother's woe.  
 What shall he do? His once so vivid nerves,  
 So full of buoyant spirit, now no more  
 Inspire the course; but fainting breathless toil,  
 Sick, seizes on his heart; he stands at bay;  
 And puts his last weak refuge in despair.  
 The big round tears run down his dappled face;  
 He groans in anguish, while the growling pack,  
 Blood happy, hang at his fair jutting chest  
 And mark his beauteous chequer'd sides with gore.

**STAG.**—Term for a young game cock during his second year. For the whole of the first year, he is called a chicken; from which time to the completion of the second, he is a stag; and from thence forward, a cock. In regular matches and mains for considerable sums of money, very few are brought to pit before they are of that age; unless it is made, and so agreed on both sides, in which case it is called a stag main, or main of stags.

**STAGGERS.**—For example, the mad-staggers (says Osmer) has been treated by all the old writers as an apoplectic or nervous disorder; which alleged nervous disorder is a something they know not what; but is clearly a kind of subterfuge for what they do not know. But the mad-staggers is in reality a fever, of which I have cured many horses by the same means as those directed for the fever, called distemper. In like manner, all the different diseases called by the names of convulsions, epilepsy, vertigo, and apoplexy, are, nineteen times in twenty, no other than secondary effects, or symptoms of fever. Just so it is amongst men, some of whom have with a fever the concomitant symptoms of coma, or sleepiness, delirium, or madness, spasms, convulsions,

&c. yet these affections in the horse are always treated as original diseases by our farriers; who, to give the strongest proofs they can, of their ignorance in these matters, have lately found out a new way, by which they expect to cure these disorders, that is, by giving the horse a drench through the nose instead of the mouth!—if horses were to doctor men, could they act with less rationality?

But, so far from depending on the nervous system, some of those symptoms that acquire the names of vertigo, apoplexy, and epilepsy, may happen to the horse simply from repletion, when there is no apparent fever, and from various other causes; for instance, the worms in horses, as well as in men, will occasionally produce the appearance of all other diseases. Now those concomitant symptoms of delirium, coma, convulsions, &c. do not require our particular attention in horses as in men; but when the fever is attended with any of those symptoms, large and repeated bleeding is our chief dependance, more especially if the jaws are shut so fast as to render it impossible to give the horse any internal medicine. Here again, incisions of the skin, before recommended, (No. 1 or 2,) as drains, and clysters should

be used, and nitre given internally, as soon as the horse's closed mouth relaxes, taking care to join some laxative salts with it, to keep the patient's body open, or rather loose.

*Fever Powder, No. 1.*

Nitre, powdered, one ounce ;

Camphor, two drachms ;

mix, and give in mucilage of gum arabic ; or the whole in oatmeal gruel, twice a day, and give until the water produced is abundant.

*Fever Ball, No. 2.*

Nitre, powdered, six drachms ;

Camphor, one drachm ;

Tartrate of antimony, one drachm ;

Liquorice powder, two drachms ;

mix, for one dose, with mucilage of gum arabic and meal, enough to form the ball ; give a horn of gruel upon the ball.

Nitre should always be accompanied by the gum, lest it occasions pain in the horse's stomach. When much water is passed, cease the nitre altogether.

A case of staggers occurred in my practice which convinced me, more than ever, of the value of salts in the cure of horses' diseases, and this particular ailment eminently so. It so happened, that a horse, mad with the staggers, (caused by walking round and round, generally) broke out of a stable belonging to a gunpowder-mill, and got to a large cistern of water, in which so much saltpetre was dissolved, that it was barely in a state of fluidity. Hereof he drank, or rather swallowed, several gallons ; this soon promoted a very copious secretion by the urinary passages, after which, he became immediately well, without any other assistance. This case is mentioned here to shew the good effects of nitre in fevers, and that some horses are able to take any quantity of this salt ; and yet others, from a difference of constitution, more particularly when they eat grass, shall not be able to take the smallest quantity, without being affected with gripes or cholic ; therefore, it is always best to begin with a small quantity, not less than an ounce, which should be mixed, and made into a ball, with some mucilage of gum arabic and meal ; and if the horse be not affected with cholicky pains, the dose may, by degrees, be increased to a greater quantity, according to the different age and symptoms. But when gripes ensue from the use of this salt given in small quantities, you will find that tartar soluble, sal regeneratum, or any such kind of neutral salt, will answer your purpose, given twice or thrice

a day in such quantities as you would use nitre.

**STALING.**—A term used to signify, in a horse or mare, the act of evacuating the urinary bladder. It is a humane and necessary practice to suffer horses to void their urine at full leasure ; and to encourage them to it by whistling, or any other of the soothing methods which they may understand.

Horses are seldom subject to stale blood, unless when they have received some strain in the kidneys, or when some blood-vessel has been ruptured about the neck of the bladder, or from some erosion either there or in the urethra, by which some of the small blood-vessels may have been laid open and send forth a bloody discharge ; but when this happens, it is generally very small in quantity, and often goes off without the help of medicine. These effects may also proceed from sharp rugged stones in the kidneys, ureters, or about the neck of the bladder ; though, from what authors have hitherto observed on the subject, horses are not very frequently so affected from this cause, but, for the most part, in consequence of very hard labour, or some other ill usage.

In this case the urine becomes bloody, and sometimes even clear blood will pass off just after staling. In order to effect a cure, if the horse be fat and lusty, it will be proper to bleed plentifully, but if he be low in flesh, more sparingly, or not at all. It has been the practice to follow this by the internal use of mild astringents, such as the following, from Gibson :

Take Conserve of red roses,

Locatelli's balsam, of each six drs ;

Spermaceti, half an ounce ;

Nitre in powder,

Irish slate, of each two drachms ;

Syrup of poppies, sufficient to make it into a ball.

This, he says, generally cures any horse that stales blood, while the disorder is recent, and when the blood does not proceed from some inward ulceration. It may be repeated until the symptoms go off and the horse stales freely. If the bloodiness of the urine proceed from an affection of the kidneys, neck of the bladder, or urethra, which may be known by pain and interruption in staling, and by a purulent sediment in the urine, it must be treated as under those heads, and, if obstinate, with mercurials and such other medicines as may be required.

The most remarkable case I ever met with of this kind, says Gibson, was that of

a troop horse, that happened to be overstrained in riding, perhaps at a time when his bladder was full and wanting to stale. When he came home, I found him much out of order, drooping, hanging his head, and off his stomach, and after staling, voiding sometimes about a gill, sometimes about half a pint or more, of fresh blood, which I saw several times lie clotted on the pavement or among his litter. This horse was treated with rowelling, bleeding, and the use of the last-mentioned prescription, which soon relieved him, and was repeated till all the symptoms were removed. After which, some mild purges were exhibited, whereby he was enabled to do his work as usual. Yet after two years, upon some other occasion, the same symptoms returned, but not so violent, and were soon cured with the use of the same remedies.

Modern veterinarians will not be inclined to attribute much of the credit of the cure, in the cases here cited, to the balls prescribed by Gibson. Bleeding, rest, and the use of diluents, were probably the actual causes of restoration. If any thing would have contributed to the further success of this plan, it is, perhaps, the free use of mucilaginous solutions, as those of gum arabic, &c. as in the strangury. See STRANGURY.

**STALKING HORSE.**—A device formerly made use of for the purpose of approaching wild fowl. Sometimes a real horse was used, sometimes the skin of one stuffed. This device has, however, been laid aside. The mode of operation was for the fowler to approach his object so as not to be seen, as birds are not alarmed at the sight of a horse. The horse formerly used for driving partridges into the tunnel net has also given way to more expeditious methods.

**STALL.** The partitions into which a stable is divided are denominated stalls; and the space allotted to each horse is called a stall. These, in stables constructed with judgment, and erected with a necessary respect to health and convenience, should never be less than nine or ten feet high, and six feet wide; the height will contribute much to the equal temperature of the air; and the width will contribute to the comfort of the horse in an occasional extension of his extremities, as well as prevent many of those injuries sustained in too suddenly turning in narrow and confined stalls, particularly in the common livery stables of the metropolis. In large establishments there are single stalls (called loose boxes)

of such dimensions as are adapted to the accommodation of horses either sick or lame, where they are then at liberty to expand at full length, and enabled to roll at their ease; these are of great utility, and few sportsmen continue long without them.

**STALLION** is the appellation given to a perfect horse, not mutilated by the operation of castration, but preserved in a state of nature, for the purpose of propagation. Stallions should be of great strength, according to the distinct breed they are intended to promote; of correct shape, uniform make, and corresponding symmetry; free from every kind of hereditary taint; good eyes, long forehead, short back, round barrel, wide chest, straight legs, free from splints before, and spavins behind. Although it is a difficult task to obtain perfection, some little circumspection may be necessary, in coming as near to it as circumstances and situation will permit. Experimental observation has produced demonstration, that stallions really blind, or with eyes defective, have produced colts of a similar description; such defects not appearing in their first two or three years, nor, indeed, till they have been worked, and the powers brought into action. Instances are never wanting of the great number annually disposed to breed, who as annually repent for want of these prudent precautions. Not only the above points, but the temper and disposition of a stallion should be also attended to: vicious and restive horses should be equally avoided; those imperfections are very frequently transmitted from sire to son, and continued to posterity.

**STARS** are distinguishing marks in the foreheads of horses. They are usually white. Solleysel says, the method of making a star is as follows: "if you would have a white one in his forehead, or indeed in any other part of his body, first, with a razor, shave away the hair, of the width or bigness that you would have the star to be; then take a little oil of vitriol in an oyster shell, and dip a feather or piece of stick into it, for it will eat both linen and woollen, and just wet it all over the place that you have shaved, and it will eat away the roots of the hairs, and the next that come will be white. It need not be done above once, and may be healed up with green ointment."

**STARTING.** In horses, is an imperfection, if it becomes habitual, that is of the most dangerous description. It is

exceedingly different from a horse skittish, wanton, and playful only, for which the rider is always prepared; and if a good horseman, it is generally as pleasing to one as to the other. But when a horse is continually in fear, and alarmed at every object unlike himself, he not only sometimes snorts and stops suddenly in the midst of a rapid career of either trot or gallop, but, by an instantaneous spring of five or six feet, brings the rider over his head, or dismounts him on one side or the other. It is not at all matter of surprise, that most of the young horses brought from the country, should at first be alarmed at the infinite variety and velocity of carriages, as well as with other strange and unaccountable objects, to which they must have been entirely unaccustomed before they reached the environs of the metropolis. Horses of this

description, (good tempered, and not viciously inclined,) are never known to be long so disposed, provided they are treated tenderly, and encouraged mildly to pass the object by which they have been so suddenly, accidentally, and perhaps unnecessarily, alarmed: but when the persons who ride them, permit passion and inhumanity to predominate over reason, obstinacy on one side often begets opposition on the other, and accident or death frequently ensues.

STERN. The tail of a hound, greyhound, or pointer, is sportingly so called.

STEW is a small reservoir of water, to which fish are brought from larger receptacles where they are bred or caught, and there deposited for the daily use of the family, the supply being constantly kept up in proportion to the domestic consumption.

STOAT. The stoat or ermine differs from the weasel in size, but not in disposition: it is usually nine inches long; the weasel is not much above six. The tail of the stoat is always tipped with black, and is longer in proportion to its body than that of the weasel. The edges of the ears and the ends of the toes in this animal, are of a yellowish white; and although it is of the same colour with the weasel, being of a lightish brown, and although this animal, as well as the weasel, in the most northern parts of Europe, changes its colour in winter, and becomes white, yet even the weasel may be easily distinguished from the stoat, by the tip of the tail, which, in the latter is always black.

The stoat is sometimes found white during the winter season in Great Britain, and is then generally called the *white weasel*. Its fur, however, having neither the whiteness, the closeness, or the thickness of those which come from Siberia, is with us, of little value.

In Norway, the stoat, or ermine, lives among the rocks, catches mice like a cat; is particularly fond of eggs, and when the sea is calm, it will swim over to the islands which lie near the coast of Norway, where there are vast quantities of sea fowl, in order to plunder the nests. Pontopiddan remarks, that "this animal, although small, kills those of a much larger size, as the rein-deer and bear. He jumps into one of their ears when they are asleep, and adheres so fast by his teeth, that the creatures cannot disengage him. He likewise surprises eagles and heathcocks, by fixing on them, and never quitting them, even when they mount in the air, until the loss of blood makes them fall down."

The Norwegian bishop, we are aware, dealt occasionally in the marvellous; but whatever credit may be given to what we have just quoted from him, it is well known that, in this country, nothing is more destructive to game than the stoat. It is uncommonly destruc-

tive in a rabbit warren; it will seize hares, and unerringly destroy them:—it seems never satiated with blood:—it is in vain that the hare attempts to escape by flight, her deadly enemy adheres with all the tenacity of a leech, and, where it can obtain a sufficient supply, the stoat will merely suck the blood and leave the carcase untouched. It will also seize partridges and pheasants on the nest, will destroy their eggs; and, in fact, on the score of depredation amongst them (as we have already observed) it has scarcely an equal.

When a domestic hen happens to deposit her eggs at a distance from the house, it sometimes happens that a stoat and a crow contend for the prize. From having been in the habit of committing depredations of this kind, they are perfectly aware of the signal (the cackling of the hen): therefore, while the hen is sitting on the nest, a crow may sometimes be seen on a neighbouring tree, and a stoat at the mouth of his hole waiting the important moment with anxious expectation. The moment the hen cackles, a race commences between the winged competitor and the little quadruped just mentioned, and whichever reaches the spot first, bears off the prize in triumph.

As the stoat is so destructive to game, all keepers should make it a primary consideration to rid their manors of a creature so mischievous. Stoats are easily caught in traps, particularly, it is said, if the bait be rubbed with musk. But even the stoat, destructive as it is to the hopes of the sportsman, is not without its redeeming qualities:—it will pursue the rat as eagerly and as fiercely as the ferret; and on this account it is sometimes a favourite with the farmer. It kills mice also, and all the smaller kinds of birds which it is able to surprise.

There are some dogs, that, though they will worry rats, will not touch the stoat; and whenever these creatures are killed, like most others of the weasel kind, they emit a very offensive fetid effluvium.

**STONE.** A term upon the turf, and used in matches, plates, and sweepstakes, to denote or imply what weight each horse is to carry; that is, so many stone, so many pounds. Every stone is fourteen pounds, and this is called horseman's weight.

**STOP.** In the manege, a pause, or discontinuation of going. In order to stop a horse, the rider should, in the first place, bring-to the calves of his legs; and bending his body backwards, raise the bridle hand, without moving the elbow; then vigorously extend the hams, and rest upon the stirrups, to make him form the times or motions of his stop, in fal-cading, with his haunches, three or four times. The opposite term to stop is parting. Formerly, the stop of a horse was called parade.

**STOPPING.** The filling the hollow of a horse's foot with poultice, cow-dung, or any other moist application. It has

the effect of softening the sole, and, on some occasions, may be advantageous, though it is frequently misapplied.

**STRAIN.** See **SPRAIN**.

**STRANGLES.** The French and other foreign writers have compared the strangles in horses to the small-pox in men; and as the small-pox is more incident to children than to grown persons, so it has been observed by these writers, that the strangles chiefly affects colts and young horses, when they catch inveterate colds; which is very true, for horses are seldom subject to strangles after six years old, though Gibson speaks of some horses that he knew to have had this distemper at seven and eight, and sometimes at nine or ten, though these instances, he says, are not very common. The strangles is also said to resemble the small-pox in this, that it never seizes horses oftener than once; whereas many other distempers, proceeding from common causes

and accidents, will return as often as there are the proper causes to produce them. But however that be, it is probable that the strangles is a critical swelling, which, when it suppurates and breaks, discharges somewhat obnoxious to the constitutions of young horses, as they are usually rendered more healthful than they were before.

The strangles begins with a swelling between the jaw-bones, sometimes pretty low among the muscles of the tongue, attended with great heat, pain, and inflammation, sometimes to such a degree, that a horse is scarcely able to swallow till the tumour suppurates.

Many colts have the strangles at grass, and the tumour comes to maturity and breaks, yielding a very plentiful discharge, without any other help than what nature affords; though in some cases there is very great malignity, with a purulent running at the nose, which is often dangerous. Those colts, however, that escape the strangles at grass, are liable, for the most part, to be seized when they are first taken up and put to business; and we often observe the change of diet, an alteration in the air, &c. bring on the strangles. Other causes may be, their catching cold, shedding their teeth, or whatever may induce pain, or bring on irritation at any critical time upon the throat and jaws.

When the strangles are coming upon a horse, he feels unusually hot, and sometimes very feverish, with a painful cough; some go quite off their stomachs, others are only dainty, or eat and drink with pain in chewing and swallowing. When the swelling begins on the inside of the jaw-bone, it is much longer in coming to maturity than when it begins more towards the middle. When the skin is tight and much stretched over the swelling, and that feels unusually dry, and hot, the swelling will in that case be large before it breaks, and yield a plentiful discharge. When the swelling of the strangles rises between the jaw-bones, under the middle of the tongue, it is always the most favourable; but if it rises upwards among the glands, and is divided into several little tumours, it is not so kindly, but is apt to break in several places and at different times before it sinks, which renders the case more tedious and troublesome.

When the strangles begin directly in the upper part of the throat, towards the head of the wind-pipe and gullet, it hinders a horse sometimes from swallowing

for several days, until the tumour grows full and large on the outside. This degree of the strangles is not altogether without danger of a suffocation. The pressure made upon the head of the wind-pipe makes the horse's eye look fixed, as if he was convulsed, with his nose turned outwards, and his nostrils open for want of breath; which symptom continues till the tumour, growing ripe, breaks and runs off. But the worst and most dangerous kind of strangles is, when at the same time that a horse is swelled under the jaws, he runs also at the nose, which Gibson attributes either to some constitutional malignity, or to bad management; and this is what some call the false or bastard strangles.

This disease seldom proves dangerous, unless the efforts of nature are interrupted. Doing much in this case, says Gibson, is worse than doing too little, for the strangles seldom needs any other help than to assist suppuration, by keeping the swelling always moist with camphorated hog's lard.

Some use poultices to the strangles; but besides the trouble of applying them, and renewing them often, they frequently prove hurtful, by being composed of materials that are too stimulating, as turpentine, &c. Besides, if the poultices are not kept close, they are apt to chill the part, and to repel, rather than promote, a discharge of the humours, and this often leaves a dry and obstinate cough, or endangers the horse's eyes. Another error in the cure of the strangles, is opening the tumour before it comes to maturity, which defeats the purpose of nature, for there are found, in that case, callous swellings under the throat, with a gleeting ulcer, sometimes followed by a plentiful running at the nose, which, without very great care, will end in the glanders. Of this, Gibson speaks of having seen several instances. Therefore, if the strangles proves kindly, and without uncommon symptoms, he insists, there is no need of any other application, besides keeping the part continually moist with some lenient ointment, till the tumour breaks and discharges itself, which, for the most part, happens in about five or six days. Some farriers are apt to open the tumours, or widen the orifice with tents; but this is altogether unnecessary, and often injurious, for nature does the business here effectually, unless the formation of matter has been hindered by some improper application.

If the strangles begin with great pain

and inflammation, as sometimes happens; if the horse's eyes are fixed, and he looks convulsed; his neck much swoln, and his jaws stiff, with his nose turned outwards; it is then necessary to take away a sufficient quantity of blood, to foment and apply a bran poultice to the part, covering it with a thin woollen cloth; and this should be persevered in till it comes to maturity and breaks. Sometimes the inflammation is so great as to destroy the skin that incloses the matter, by which means it falls off in pieces, like an eschar made by a caustic, and exposes the interstices of the muscles, and contiguous glands. But here also nature will effect a cure, without any other help, besides what has been already recommended; for the cavity is soon filled by a new growth of flesh, and covered with skin and hair, as perfect as at first. Sometimes the strangles break inwardly, and the matter is discharged chiefly by the mouth; and when it is so, the horse's mouth may be washed once or twice a-day, with equal parts of brandy and vinegar, with a spoonful of honey to each pint. This, with warm soft diet, will perfect the cure without any other help, and the swelling on the outside will soon wear off.

In some cases, where there is little swelling and inflammation, the horse will eat and drink without pain; and though there be a collection of matter, yet when it is small, it sometimes continues long without breaking. When matter is formed in this way, and may be felt by gentle pressure with the finger, Mr. Denny advises us to open the tumour with a lancet in the most depending part, as this prevents any ulceration of the skin. If the tumour has been very large, he advises that a seton should be introduced, to support the discharge till the cavity be filled up, after which it is to be withdrawn.

If the animal does not recover his strength (says the same writer) but becomes weaker, with the continuance of a fetid discharge from the nose, accompanied with a cough and difficult respiration, the following mixture should be given every four hours, until an alteration takes place:

Take of Peruvian bark, in powder, half  
an ounce;  
Liquorice root, sliced,  
Aniseeds,  
Coriander seeds, bruised, of  
each one ounce;  
Water, two quarts.

Boil them for ten minutes; then strain, and add, of

Tincture of opium, two drs.;  
Honey, two ounces. Mix.

When the danger is removed, discontinue the mixture, and give the following ball every morning and night, with mashes of malt or oatmeal, and bran, to recruit the animal's strength:

Take of Peruvian bark, half an ounce;  
Myrrh, in powder, two drs.  
Gentian,  
Aniseeds, of each half an oz.  
Honey, enough to make them  
into a ball.

The horse must have gentle walking exercise, and good grooming, daily; and after his strength is returned, a dose of mild mercurial physic will be proper."

Gibson observes that horses have derived great benefit from the use of guaiacum, where the glandular discharges have been too liberal. "I had a fine horse (says he) committed to my care, that was sent a journey in wet weather, the day after the strangles broke. He discharged a gleety water from under his jaws, and matter of the same consistence at his nose, and this had continued for several months, so that he was become quite extenuated, and exceedingly weak; for the running under his jaw was so profuse, that the litter was continually wet under him. This horse was soon cured, and restored to perfect health and vigour, by strong decoctions of guaiacum. But I believe such cases as this seldom happen, and, indeed, very few horses would have stood it so long, but this was naturally a horse of great spirit and vigour, which no doubt contributed very much to his recovery." He also speaks of several young horses that had small loose kernels under the jaws, with a running at the nose, of a white matter, sometimes more, sometimes less, for a year or two, and sometimes they would be altogether free from it. In these cases, he says, the guaiacum decoctions were of great benefit.

**STRANGURY.** A disease whose characteristic symptom is a partial suppression of urine, but at the same time unaccompanied by fever, or other general symptoms.

It is the effect of irritation, occasioning a spasmodic contraction about the neck of the bladder. Mr. Denny recommends the following treatment.

"If much irritation prevails, take away four or five pints of blood, and give the following ball and mixture:

Take of Camphor, in powder, two drs.  
 Nitre, in powder,  
 Common soap, of each half an ounce;  
 Balsam of Capivi, enough to make a ball.

Take of Gum arabic, in powder, two ounces;  
 Tincture of opium, half an oz.  
 Simple peppermint water, two pints.

Dissolve the gum first in the mint water, and then add the tincture of opium.

Repeat this in the course of six or eight hours, if necessary; taking the precaution of clearing the bowels with the following clyster:

Take of Tincture of opium, two drs.  
 Oatmeal gruel, three quarts;  
 Common salt, four ounces;  
 Olive oil, half a pint. Mix.

The horse's food should consist of bran mashes, warm water, or gruel. The cure may also be promoted by applying fomentations of chamomile flowers to the perinæum."

When the stoppage of urine proceeds from matter in the bladder, derived from the kidneys, which happens in some colds, or after some kinds of fevers, Gibson recommends a decoction made with roots of marsh-mallows; to which he adds nitre, gum arabic, &c. He says he never observed any stoppages that were insurmountable, either in the neck of the bladder or urethra in horses, as is usual in men, from gritty matter, stones, or ulcers. "These last (says he) are so rare, that among the great numbers I have been concerned with, I can remember only one instance of schirrous and sinuous ulcer, or rather cancerous, in the urethra of a horse, that spread itself through a considerable part of the cavernous body of the penis. This continued several years, but was never cured, neither could it admit of a cure at the time I was made acquainted with it."

**STRIGIL, or STRIGILIS.** An instrument to scrape off the sweat during the gymnastic exercises of the ancients, and in their baths: strigils were made of metals, horn, or ivory, and were curved; some were made of linen. Something of this kind is used to remove the foam and sweat on a horse's body after a race.

**STRING-HALT.** An involuntary and convulsive motion of the muscles, which extend or bend the hough. When it seizes the outside muscles, the horse

straddles, and throws his legs outwards; but when the inside muscles are affected, his legs are twitched up to his belly. Sometimes it is only in one leg; sometimes in both. It generally proceeds from some strain or blow, and the cure is difficult, and seldom attended with success; though, in the beginning, a string-halt may be removed with good rubbing and the use of fomentations, with daily but moderate exercise. The last refuge is usually the fire, which Gibson says has been known to answer at least so far as to prevent absolute lameness.

**STUBBED.**—A horse is said to have sustained this injury, when in hunting amongst the stumps of newly cut coverts and underwood, he is punctured, cut, or bruised, in any part of the foot, coronet, or fetlock, by some of the infinity of stubs with which newly cut copses so plentifully abound. When accidents of this kind happen, the applications must depend entirely upon the magnitude of the injury received. In all slight cases, amounting to little more than simple laceration, friar's balsam, tincture of myrrh, or even common vinegar, may soon close the mouths of the vessels, harden the surface, and effect a cure. Where swelling and inflammation ensue, poultices must follow; and wounds must of course be treated as such.

**STUB NETS.** See **NETS**, page 560.

**STUD** is a term applicable to three distinct meanings, and is so used in its different significations. A stud, in its more extended acceptation, applies to an aggregate collection of horses, without giving priority to any particular sort; as the person having a great number of horses, is said to have a very large stud; but the term, in its divided and sub-divided state, proves more extensively comprehensive. One is in possession of a very expensive racing stud; another has a numerous stud of hunters; and a third, still more opulent, or still more fashionable, shall have a breeding stud to produce an annual supply for the two preceding.

**STUMBLING** is so great an imperfection in a horse, that it affects his intrinsic worth, in proportion to the readiness with which it is perceived. Horses having short forehands, large heads, and thick shoulders, are the most subject to this defect of any other formation: those low at the point of the withers, (which is called being lower before than behind,) in addition to the deficiencies already mentioned, are the worst of stumblers; the whole forming such a combination of bad points,

as not to leave one enlivening hope of reformation.

**SUMPTER HORSE.** A name for a horse that carries provisions and necessities for a journey.

**SUPPLE**, in the manege. To supple a horse is to make him bend his neck, shoulders, and sides, and to render all the parts of his body more pliable.

**SURBATING** has been, till within a very few years, used to signify a hoof so battered, bruised, and worn, with bad shoeing, bad shoes, and sometimes with no shoes at all, that the horse, having hardly any feet to stand upon, was then said to be surbated; which, in more explanatory and comprehensive language, is neither more or less than the sole of the foot so completely destroyed, that a horse in such situation is now said to be foot-fundered, who was formerly said to be surbated.

**SURFEIT**, a term unknown to modern veterinarians, though, with those of the old school, of very extensive import. We must of necessity, therefore, stand indebted to some individuals of the former class for the following explanation of it. Bracken says, a surfeit is principally understood to be all such maladies or distempers as proceed from excessive and immoderate feeding, but especially upon unwholesome food, from cold and hard riding, &c. whereby a horse forsakes his meat, and is infected with hard swellings, which, if they happen to fall upon the joints, will in process of time occasion lameness and many other disorders.

Surfeits arise from various causes, but are commonly the effects of some diseases not attended to; or that have been ill cured. A horse is said to be surfeited, when his coat stares and looks rusty and dirty, though proper means have not been wanting to keep him clean. The skin is full of scales and dander, that lie thick and mealy among the hair, and is constantly supplied with a fresh succession of the same, for want of due transpiration. Some horses have hurdles of various sizes, like peas or tares. Some have dry fixed scabs all over their limbs and bodies; others a moisture attended with heat and inflammation: the humours being so sharp, and violently itching, that the horses rub so incessantly, as to make themselves raw. Some have no eruption at all, but an unwholesome look, and are dull, sluggish, and lazy. Some appear only lean and hide-bound, others have flying pains and lameness, resembling a rheumatism: so that,

in the surfeits of horses, we have almost all the different species of scurvy, and other chronical distempers.

The following method of cure, Gibson says, is usually attended with success in the dry species. First take away about three or four pounds of blood: and then give the following mild purge, which will work as an alterative, and should be repeated once a week or ten days for some time:—

Take of Socotrine aloes, six drachms,  
or one ounce;  
Gum-guaiacum, half an ounce;  
Diaphoretic antimony,  
Myrrh, of each two drachms;  
Make into a ball with syrup of buckthorn.

In the intermediate days, an ounce of the following powder should be given morning and evening in the feeds:—

Take of Cinnabar of antimony, finely powdered, half a pound;  
Crude antimony, in fine powder, four ounces;  
Gum-guaiacum, also in powder, four ounces.

Make into sixteen doses, for eight days.

This medicine must be repeated till the horse's coat is well, and all the symptoms of surfeit disappear. If the horse is of small value, two or three common purges should be given; and half an ounce of antimony, with the same quantity of sulphur, twice a day; or alterative balls, with camphire and nitre.

If the little scabs on the skin do not peel off, anoint them with the mercurial ointment; during the time of using which, it will be proper to keep the horse dry, and to give him warm water. This ointment properly rubbed into the blood, with the assistance of purging physic, has frequently cured these kinds of surfeit without any other assistance.

The wet surfeit, which is no more than a moist running eruption, appears on different parts of the body of a horse, attended sometimes with great heat and inflammation; the neck sometimes swells so in one night's time, that great quantities of hot briny humour issue forth, which, if not allayed, will be apt to collect on the poll or withers, and produce the poll-evil or fistula. This disease also frequently attacks the limbs, where it proves obstinate and hard to cure; and in some horses shews itself spring and fall.

In this case, bleed plentifully; avoid externally all repellers, and give cooling physic twice a week, as four ounces of le-

nitive electuary, with the same quantity of cream of tartar ; or the latter with four ounces of Glauber's salts, quickened, if thought proper, with two or three drachms of powder of jalap dissolved in water gruel, and given in the morning fasting. After three or four of these purges, two ounces of nitre made into a ball with honey may be given every morning, for a fortnight ; and, if attended with success, repeated for a fortnight longer. The powder above mentioned may be given with the horse's corn, or a strong decoction of guaiacum shavings, or logwood, may be given alone to the quantity of two quarts a day. These, and indeed all alterative medicines, must be continued for a long time, where the disorder proves obstinate.

The diet should be cool and opening, or scalded bran or barley ; and if the horse is hide-bound, an ounce of fenugreek seeds mixed with his feeds should be given for a month or longer ; and as this disorder often proceeds from worms, give the mercurial physic too, and afterwards the cinabar powders as already directed ; but as, in general, it is not an original disease, but a symptom only of many, in the cure, regard must be had to the first cause : thus, as it is an attendant on fevers, worms, &c. the removal of this complaint must be variously effected.

SWAINMOTE is a peculiar court, appertaining solely to the laws of a forest, and held three times within the year. In this court the verderers preside in the official capacity of judges ; for although the warden, or his deputy, may take their seats in the court, they have no judicial authority there. The court of swainmote may enquire of offences, receive informations, and proceed to conviction ; but judgment is not within the limits of this court ; their province extends no farther than to hear and to convict ; judgment cannot be given but from the judgment seat, where the justice in eyre presides as chief officer ; and all associated with him are called justices of the forest. This court being a court of record, can fine and imprison for offences within the forest ; and therefore if the judgment is conceived erroneous, the record may be removed by writ of error into the court of King's Bench.

SWALLOWING, the act by which food is passed into the stomach of an ani-

mal. The superior part of the œsophagus in a horse is called pharynx, and is expanded at its top. Near this the œsophagus is situated more closely to the spine than the trachea, but about the fourth cervical vertebra, and appears parallel or below it. The œsophagus is continued into the chest, when it penetrates the diaphragm about the last true rib. The human œsophagus has been divided into circular and longitudinal fibres. In the horse we distinguish two parts—an internal merely cuticular, with little or no feeling or vascularity, and an external, which is powerfully muscular, and supplied with blood-vessels. The cuticular coat lines the pharynx, and is continued in the horse through the œsophagus, and afterwards covers that part of the stomach called the insensible. See STOMACH.

Mr. Lawrence gives the following account of the "swallowing of leeches, or hen's dung," by horses. He says—This accident frequently happens to country cart horses, passing off with a slight sickness, and without notice. Whilst the horses are absent, the poultry will always watch the opportunity of examining the mangers, where they leave both dung and feathers, which ought ever to be carefully swept away, previous to feeding the horses. Horses drinking at ponds will often suck in a variety of filth and vermin. The signs of having swallowed leeches, or other vermin, are, hanging the head to the ground, and a discharge of impure saliva, sometimes mixed with blood. Give a pint of sweet oil warmed, with a glass of brandy, and a drachm of ground ginger. Scalded bran and gruel, and the oil may be repeated, if needful. A mild dose of aloes and rhubarb, with one ounce of diapente, may be given in warm ale.

When any considerable quantity of fowls' dung and feathers has been swallowed, the horse will lose his appetite, swell in his body, and void fetid slimy matter from his fundament. The same medicines and treatment, with the addition of honey, are proper, with walking exercise, the horse clothed. Sow-thistle dried and powdered, smallage seed bruised, marjoram, and the ashes of the root, leaves, and fruit, of briony, were the specifics of former times.

SWAN, THE WHISTLING. The whistling or wild swan is somewhat smaller than the tame species. The bill is three inches

long; yellowish white to the middle, but black at the end. The whole plumage is white, and the legs are black.

This species is an inhabitant of the northern regions; never appearing in England except in hard winters, when flocks of five or six are now and then seen. Martin says, that in the month of October, swans come in great numbers to Lingey, one of the Western isles, and continue till March, when they return northward to breed. A few continue in Mainland, one of the Orkneys, and breed in the little islands of the fresh-water lochs; but the principal part of them retire at the approach of spring. They are called the countryman's almanack; for their quitting the isle is said to presage good weather, and their arrival the reverse.

In Iceland these birds are an object of chase. In the month of August they lose their feathers to such a degree as not to be able to fly. The natives, at that season, resort in great numbers to the places where they most abound; and are accompanied with dogs, and active and strong horses, trained to the sport, and capable of passing nimbly over the boggy soil and marshes. The swans will run as fast as a tolerably fleet horse. The greater number are taken by the dogs; which are taught to seize them by the neck—a mode of attack that causes them to lose their balance, and become an easy prey.

Notwithstanding their size, these birds are so extremely swift on the wing, when in full feather, as to make them more difficult to shoot than almost any other; it being frequently necessary to aim ten or twelve feet before their bills. This, however, is only when they are flying before the wind in a brisk gale; at which time they seldom proceed at less than the rate of one hundred miles in an hour; but when flying across the wind or against it, they are not able to make any great progress.

This species has several distinctions from that called by us the tame swan: but the most remarkable one is, the strange form of the windpipe; which falls into the chest, then turns back like a trumpet, and afterwards makes a second bend to join the lungs. By this curious construction, the bird is enabled to utter a loud and shrill note. The other swan, on the contrary, is the most silent of all the feathered tribes; it can do nothing more than hiss, which it does on receiving any provocation.—The vocal swan emits its loud notes only when flying or calling: its sound is, *whoogh, whoogh*, very loud and shrill, but not disagreeable when heard high in the air and modulated by the winds. The Icelanders compare it to the notes of the violin; they hear it at the end of their long and gloomy winter, when the return of the swans announces also the return of summer; every note therefore must be melodious which presages a speedy thaw, and a release from their tedious confinement.

It was from this species alone that the ancients derived their fable of the swan's being endowed with the powers of melody. Embracing the Pythagorean doctrine, they made the body of this bird the mansion of the souls of departed poets; and then attributed to the birds the same faculty of harmony which they had thus possessed in a pre-existent state. And the vulgar, not distinguishing between sweet-

ness of numbers and melody of voice, thought that real which was only intended figuratively,—The mute or tame swan never frequents the Padus; “and I am almost equally certain, (says Mr. Pennant) that it was never seen on the Cayster, in Lydia; each of which are celebrated by the poets for the great resort of swans. The Padus was styled *Oloriferus*, from the numbers of these birds which frequented its waters; and there are few of the poets, either Greek or Latin, who do not make them its inhabitants.”

SWAN, THE TAME OR MUTE. The mute swans are found wild in Russia and Siberia; in England they are very common in a domestic state. They are seen in great plenty on the Thames; where they are esteemed royal property, and it is accounted felony to steal their eggs. In the reign of Edward IV. swans were held in such estimation, that, “no person who did not possess a freehold of the clear yearly value of five marks” was permitted to keep any.

Nothing can exceed the beauty and elegance with which the swan rows itself along in the water, throwing itself into the proudest attitudes imaginable before the spectators; and there is not perhaps in all nature a more lively or striking image of dignity and grace. In the exhibition of its form, we see no broken or harsh lines, no constrained or abrupt motions, but the roundest contour and the easiest transitions imaginable: the eye wanders over every part with pleasure, and every part takes new grace with new postures.

The swan, with arched neck  
Between her white wings mantling, proudly rows  
Her state with oary feet.

It exhibits, however, but an inelegant appearance on land.

The swan will swim faster than a man can walk. It is very strong, and at times extremely fierce: it has not unfrequently been known to throw down and trample upon youths of fifteen or sixteen years of age; and an old swan, we are told, is able to break the leg of a man with a single stroke of its wing. A female, while in the act of sitting, observed a fox swimming towards her from the opposite shore: she instantly darted into the water, and, having kept him at bay for a considerable time with her wings, at last succeeded in drowning him; after which, in the sight of several persons, she returned in triumph. This circumstance took place at Pensey, in Buckinghamshire.

Swans are very long-lived, sometimes arriving at the great age of a hundred years. The flesh of the old birds is hard and ill-tasted; but that of the young, or cygnets, was formerly much esteemed.

The swan makes its nest of grass, among reeds; and in February begins to lay, depositing an egg every other day till there are six or eight. These occupy six weeks in hatching. Dr. Latham says, he knows two females that for three or four years past have agreed to associate; and have had each a brood yearly, bringing up together about eleven young: they sit by turns, and never quarrel.—When in danger, the old birds carry off the young ones on their backs.

**SWAYING OF THE BACK.** A kind of lumbago known by a pain and weakness in the loins of a horse. It may be caused by a fall, the carrying of some heavy burden, or some other violent accident; or a relaxation or spasm of the muscles of the back. The first thing to be done in this case, is to take away plenty of blood; after which a blister is to be applied, and those things given inwardly that promote sweat. Mr. Snape advises that the horse may be sweated in a dung-hill, if the common remedies fail. His diet must be opening, and all imaginable care taken to keep down a fever. He ought to be girt pretty firm over his loins, yet not so as to hinder the motions of his flanks. Gibson says, he ought also to be hung up, or kept in a steady posture; but if the weakness continues, you may proceed to the fire, by piercing the skin above the muscles that lie on each side of the spine, avoiding the flanks, otherwise it will be apt to creat a swelling in the sheath, which would bring on a fever.

**SWEAT** is the transpiration of perspirative matter through the skin by the effect of an increased circulation of the blood. This, in a moderate degree, is so conducive to the promotion of health, that those horses who regularly enjoy exercise to a proper state of perspiration, attain the highest condition; provided they are taken care of in proportion to the exercise each has had, or the work he has undergone. By the appearance of a horse in a high perspiration, immediate judgment may be formed of the property of his blood; and in a collateral degree, of the state of his health; for when a horse in good condition is under a profuse perspiration, the sweat is so congenially incorporated with the coat, (particularly if the horse is well bred,) and the hair lays so uniformly one way, that if the sun happens to shine, it seems a covering of satin: on the contrary, when a horse, after equal (or, in fact, much less) exertion, bears a greasy kind of perspiration upon the surface, with the coat turning in different directions, bearing a gross matted appearance, the blood is in an improper state, and the horse in very bad condition. Sweating a horse in the stable, by the ad-

ministration of medicine, is a practice, the propriety of which has not hitherto been clearly ascertained.

**SWEATING FOR THE TURF.** See **RACE HORSE, TRAINING, THE.**

**SWEATING OF JOCKIES** is a ceremony which every jockey is under the necessity of going through when engaged to ride, and the horse is to carry less than his own natural weight. For the reduction of weight, jockies are obliged to encounter great inconveniencies, particularly when they have much to lose, and a very short time to lose it in. The means of reducing themselves to the weight required are various, and depend upon the greater or lesser quantity they wish to lose in a given time, and have to waste themselves accordingly. If they have but two or three pounds to lose, they will waste that in a single day's abstinence, and a morning and evening's walking: should four or five pounds be required, a gentle laxative, followed by two or three days' extra walking, with an additional waistcoat or two, will generally carry their point: if more is necessary to be lost, it is sometimes a hazardous reduction, and great exertions are made to effect it: additional purgation, continued abstinence, increased perspiration, and almost perpetual exercise, all which, if persevered in to an extreme, tend to undermine the natural stamen by which the frame is supported, and absolutely saps the constitution. Instances have been numerous, where jockies have undertaken to waste fourteen or sixteen pounds, and even more, against the day of running.

**SWELLED LEGS.** See **GREASE, &c.**

**SWELLING IN THE SHEATH OR GROIN** of a horse externally in good health, and without any predominant symptoms of pain or disquietude, is sometimes of little consequence; denoting no more than a general plethora, or distension of the vessels, which immediate bleeding, followed by gentle friction, and moderate evacuants, may be expected to remove: but if it makes its appearance at the crisis of any inflammatory disorder, it may be considered as a very unfavourable prognostic, and the advice of a skillful veterinarian becomes necessary.

## T

**TAIL.** Upon the uniform shape and setting on of a horse's tail, his good or ill appearance greatly depends. When the spine is continued in a curvilinear

direction beyond the rump, and the basis of the tail is formed too low in the quarters, the horse is termed "goose-rumped;" and no nicking or setting, will

ever give him the figure of a handsome horse behind. It has been a long standing maxim, that "a good horse can't be of a bad colour;" and there may probably be some who think a good horse can't have a bad tail; but a little experience in buying and selling will convince them, that the difference between the two will be little less than ten or fifteen pounds in a horse of no more than fifty pounds value. Great losses are sometimes sustained for want of a little circumspection at the moment of making a purchase; and this may sometimes proceed from the horse's having some peculiar points of attraction, in the fascinating survey of which the defects are totally absorbed; hence arises the pecuniary deficiency when the subject becomes again to be sold, particularly if to a more prudent and less hasty purchaser. The old sportsman, when going to buy, looks at the horse as if it was really his own, and he was going to sell; in doing which, he estimates his saleable value with an eye of greater accuracy, makes a tolerably fair calculation what he ought with consistency to bid, that he may sustain no great loss, should he have future occasion to sell.

**TANTERRA.** An obsolete term, formerly applied to a hare when found sitting.

**TARTAR EMETIC** is one of the most powerful, and, in respect to horses, one of the most prostituted medicines in the whole materia medica: its name here is only introduced, and its properties described, that the sporting world, as well as individuals, may be sufficiently guarded against its dangerous effects, if injudiciously administered, or secretly brought into use by practitioners of little knowledge, and less celebrity, who knowing no more of its preparation than its name, know less of its effects than its preparation. With farriers or veterinarians of this description, it is become a favourite medicine upon so many occasions, that it stands entitled to a fair, candid, and unequivocal investigation. Emetic tartar, when administered to the human frame, with a design of producing the forcible effect of a strong emetic, has never, by professional men, of the most learned, distinguished, and experienced ability, exceeded six or seven; and in truly critical cases of dangerous emergency, eight grains may have been given.

Ten grains have been known to operate so violently as to excite convulsions; twelve, to occasion death.

Amidst such incontrovertible facts, it naturally becomes a serious consideration, that men, knowing nothing of the property of medicine, should have the unrestrained privilege and permission, of bringing into use articles of so much dangerous magnitude, not only without knowing their basis, preparation, and peculiar properties, but without the power of prognosticating their probable effects. It is a circumstance worthy the attention of those possessing a number of horses for either business or pleasure, (who must consequently have some occasionally labouring under disease,) how far it may be safe, proper, consistent, or discreet, to give a horse half an ounce of tartar emetic at one dose, which, according to the above ascertained facts, will, if divided accurately into equal proportions, (and the experiments made,) take away the lives of twenty men. Those who have ignorantly adopted this practice, as ignorantly and obstinately assert the impossibility of its doing any harm; without either not possessing the knowledge, or not giving themselves time to recollect, that if seven or eight grains will distress and exhaust the human frame, by every kind of violent and sensible evacuation, to the appearance of, and in some cases to, actual death; what must be the internally destructive ravages of twenty, or thirty times that quantity, thrown into the frame of an animal, who, not having, like the human species, power to regurgitate, or throw off the offending consequence by vomit, has no alternative, but to stand a comparative barrel of combustibles, ready to burst with the effervescent conflagration raised within, and which must, in a variety of cases, be evidently productive of certain death. But such practitioners have no character to support, no reputation to lose; and they likewise well know, that dead horses, any more than dead men, tell no tales.

**TANTIVY.** Compounded, we apprehend, of two Latin words, *tanta* and *vis*, which in the ablative become *tanta vi*; tantivy with as much haste as possible. In hunting, it is used to express full gallop or full speed.

**THE TEAL** is one of the most delicate birds that graces our tables, and has been sold for seven, and frequently sells for five, shillings a couple.

The male teal weighs about twelve ounces, the female nine; the length is fourteen inches, the breadth twenty-three; the bill is a dark lead colour, tipped with black; irides pale hazel; from the bill to the hind part of the head is a broad bar of glossy changeable green, bounded on the under part with a cream coloured white line, and edged on the upper side with pale brown; the rest of the head and the upper part of the neck are of a deep reddish chesnut; forepart of the neck and breast dusky white, marked with roundish black spots; belly white, middle of the vent black; the wing coverts brown, quills dusky; the exterior webs of the lesser marked with a vivid green spot; above that another of black, and edged with white; the legs dirty lead colour. The female is of a brownish ash-colour; the lower part of the neck, and sides over the wing, brown, edged with white; the wing has a green spot like the male; the belly and vent both white.

It was at no very remote period supposed not to breed in England; but Mr. White, in his history of Selborne, has established the fact by some young teals being brought to him, which were taken in a pond on the verge of Wolmer forest. It is also known to breed in the mosses about Carlisle, as well as in Lancashire, and also in several parts of Cumberland. In France, where it stays throughout the year, it makes its nest in April, among the rushes on the edges of ponds, and which is composed of the tenderest stalks of the rushes, with the addition of the pith, and a quantity of feathers. The nest is of a large size, and placed on the surface of the water, so as to rise or fall with it; the eggs, to the number of from twelve to seventeen, are as large as those of a pigeon, of a dirty white, marked with small hazel spots: it is said to feed upon the grass and weeds which grow on the edges of waters it frequents; it will also eat the seeds of the rushes, and small fish; and the insects with which all stagnant waters are so abundantly stored. The teal is found to the north as high as Iceland, and is mentioned as inhabiting the Caspian sea to the south, and is every where deemed most excellent food.

Hearne says, like the mallard, they are found in considerable numbers near the sea coast at Hudson's Bay, but are more plentiful in the interior parts of the country, flying in such large flocks, that he has often killed twelve or fourteen, and has seen both English and Indians kill many more at one shot. At their first arrival they are poor, but generally esteemed good eating. He describes the teal as the most prolific of the water fowl at Hudson's Bay, having often seen the old ones swimming at the head of seventeen young, when not much larger than walnuts. The teal remains in these parts so long as the season will permit; for in his passage from Cumberland House to York Fort, 1775, he, as well as his Indian companions, killed them in the rivers they passed through so late as the twentieth of October; they were then entirely covered with fat, delicately white, and might be truly called a luxury.

TEAZLE, SIR PETER. See SIR PETER TEAZLE.

TEETH. See AGE OF THE HORSE, p. 8.

TEMPER. This, in a horse, is what ought very much to be regarded: because if it be good it very much enhances his

value, whereas, if it be vicious, it exposes him to many accidents. "A sullen ill-conditioned horse," says Gibson, "endangers every one that comes near him; and very often will not spare his best friends. Some are only enemies to men, but with other horses are tractable and quiet. These have not always the most true courage, as I have often observed. They are continually in motion when any one approaches towards them, expecting to be corrected, and are therefore in a constant state of enmity and defence. Others are quiet and tractable to men, and yet are so mischievous to other horses, that they will scarcely suffer any one to come within their reach. Many of this sort have true mettle and courage, but expose both themselves and other horses to kicks and bruises, which prove troublesome, and sometimes expensive to the owner, whereas a horse of the truest courage is usually the best tempered, loving to his master and keeper, and never shews his mettle completely, but when he is urged on by some noble incentive, as in a chase or running match, where there are other competitors; for when he carries a good horseman, he will then discover a sort of complacency, and seem to act every way in concert with his rider. But the reader will be apt to question, how it is possible for any one to find out the temper of a horse without trial. It must indeed be confessed, that a man who has had but small experience, can know but very little of the temper of a horse, and even those who have had the most experience, can only guess upon a superficial knowledge of a horse, so as sometimes to avoid buying such when they offered to sale; for some horses are exceedingly sly and subtle, will shew but little of their temper when they are cautiously handled, and yet will take every opportunity to do mischief, as all who have been placed much among horses must have frequently observed. A vicious horse generally lays back his ears close to his poll, though this is not always a sure indication of vice, for sometimes a very harmless horse will lay back his ears merely out of ticklishness, or from a playful disposition, but at the same time, he puts back his ears, will look pleasant with his eyes, and with his mouth catch hold of the crib, whereas a vicious horse, at the same time he lays back his ears, shows the white of his eyes, and looks sullen and dogged. Some vicious horses have a manifest frown, which they discover at all times, and which gives

their countenance such an angry aspect, as will easily enough be discovered by those who have been accustomed to horses. Besides, such horses always stand as it were in a posture of defence, having their heads raised and lofty, and one of their hind legs advanced forwards resting upon the toe, ready to lash out at the first person that offers to come near them; and this may be further observed of a very vicious horse, that he never will give a pleasant look even to the person that feeds him.

Fear is another ingredient in a horse's temper, that must very much lessen his value. A fearful horse both endangers himself and his rider, more than a vicious horse that has courage. Almost every day affords us instances of people being hurt, and sometimes killed, by starting horses, and many such horses are utterly spoiled, by the accidents their fear exposes them to. Besides that, fear in a horse is hardly ever to be overcome until he grows very old and useless, or when he happens to be continually harassed with travelling, in the constant view of all manner of objects, and even then, any thing new and uncommon will still revive his natural failing. A fearful horse may be often known at first sight by his starting, crouching, and creeping.

A horse that is very hot and fretful, is no less to be avoided. But here I would distinguish between an eager horse, that strives to be the first in the chase, the foremost in the field, and one that goes always upon the fret, which is properly what I mean here. The one goes out calmly, and never shews his mettle till a proper opportunity offers. He has those qualities that resemble prudence and courage, the other intemperate heat and rashness. A hot-tempered horse begins to fret the moment he comes out of the stable, and continues in that humour till he has quite fatigued himself, which for the most part soon happens. Such horses are not able to endure much hardship, being for the most part but poor feeders, and when they come to go a journey they soon lose their flesh, have a carrion-like look, and seldom perform it without intervals of rest. They rarely last long, for this temperature exposes them to many accidents and diseases.

A dull phlegmatic horse is the very reverse of one that is hot and fiery, and his qualities are easily known, notwithstanding all the arts of the dealer to put life and spirit into him. A sharp pair of spurs,

the frequent cracking of the whip, a stimulus under his tail, will cause him to shew somewhat of mettle, and carry himself to the best advantage; but still any tolerable judge will easily perceive that all his action is forced, and not natural. He moves as if he was in a hurry, and yet with many tokens of heaviness. Never-

theless, some such horses are of more real value, and last much longer, than those that are hot and fretful, because they are seldom hurt with labour, nor expose themselves much to accidents; and, if they prove unfit for the saddle, they may be serviceable for many other purposes.

**TENCH.** By some the tench is termed the physician of the fish, and who believe, from tradition, that the slime is so healing, that the wounded apply it as a remedy, and that even the pike will spare the tench, on account of its healing powers; but, it is apprehended, this observation has no evidence to support it, and this supposed self-denial of the pike may be fairly attributed to a different cause; namely, that tench are so fond of mud, as to be constantly at the bottom, where they are probably secure from the attacks of their voracious neighbour; for, as all the different species are, in some degree, enemies to each other, it cannot be imagined that so timid a fish as the tench would passively admit the approach of the pike.

Without vouching for the virtue of its slime upon the inhabitants of the water, its flesh is undoubtedly a delicious and wholesome food to those of the earth. The tench does not commonly exceed four or five pounds in weight; Mr. Pennant says he has heard of one that weighed ten, and Salvianus speaks of some that weighed twenty pounds: it is thick in proportion to the length; the scales are very small, and covered with slime; the eyes are large, and of a gold colour; the irides are red; he is leather-mouthed, and sometimes there is a small barb at each corner of the mouth; the colour of the back is dusky, the dorsal and ventral fins of the same hue, and those of the male much bigger than those of the female; the head, sides, and belly of a greenish cast, most beautifully mixed with gold, (especially those taken in rivers) which is in its greatest splendour when the fish is most in season: the tail is quite even at the end, and very broad.

Tench love still waters, and their haunts in rivers are chiefly among weeds, and in places well shaded with bushes or rushes; but they thrive best in standing waters, where they lie under weeds, near sluices, and at pond heads; they are much more numerous in pools and pits, than in rivers, although those taken in the latter are far preferable; they begin to spawn in June, and may be found spawning in some waters till September; their best season is from that period until the end of May.

The tackle, in angling for the tench, should be strong; a swan or goose quill float, except in rivers, where the cork is always to be preferred; the hook, No. 4 to No. 6, whipt to a sound silk worm gut, with two or three shot ten or twelve inches from it; where there are weeds, fish about two feet deep, at mid water, and sometimes rather lower, (according as they are in the humour to take;) frequently drawing the bait gently towards the surface, and letting it sink in the slowest manner: bait with the small red-worms, taken out of rotten tan, without any scouring. Should there be no great quantity of mud at the bottom, use small clay-balls, with lob-worms, as directed

in perch fishing, and let the bait be six inches from the ground; but where the mud is so deep as to cover the clay-balls when sunk, keep to the former method, and bait the spot with bits of lob-worms; when using gentles, (which should be near the ground,) throw in some at the taking of every fish, which will not only entice them to bite, but be a means of keeping them together; they should be allowed time in biting, before they are struck.

Some use the middle-sized lob or marsh worms, well scoured and dipped in tar, (which certainly has the property of alluring them,) previously ground-baiting the place with lob-worm and boiled malt, and fishing at bottom. Other baits for this fish are, the wasp-maggot, earth-bob, green-worm, shaken from the boughs of trees, paste of brown bread mixed with honey, and of white bread, in which a little tar is incorporated: the best time for angling is late and early, an hour before and after the rising and setting of the sun; but in warm, foggy, mizzling weather, with a southerly wind, the tench will bite during the greater part of the day: the tench will live long out of water, and may with safety be removed in dry straw to a considerable distance.

Tench are said to love foul and muddy more than clear water.

A tench taken out of a piece of water, at Thornville Royal, Yorkshire, which had been ordered to be filled up, and wherein wood, rubbish, &c. had been thrown for years, was in November 1801, directed to be cleared out. Persons were accordingly employed, and almost choaked up by weeds and mud, so little water remained, that no person expected to see any fish, except a few eels: yet nearly two hundred brace of tench, of all sizes, and as many perch, were found. After the pond was thought to be quite free, under some roots there seemed to be an animal, which was conjectured to be an otter; the place was surrounded, and on opening an entrance among the roots, a tench was found of most singular form, having literally assumed the shape of the hole, in which he had for many years been confined. His length, from fork to eye, was two feet nine inches; his circumference, almost to the tail, was two feet three inches; his weight, eleven pounds nine ounces and a quarter; the colour was also singular, his belly being that of a charr, or a vermilion. This extraordinary fish, after having been inspected by many gentlemen, was carefully put into a pond; but either from confinement, age, or bulk, it at first merely floated, and at last, with difficulty, swam gently away.

**TENDONS** are the elastic covering of the muscles, composed of an infinity of fibres, which, in their aggregate, form a substance of great strength, and appropriate contraction and elongation, for all the purposes of expansion and flexibility. The tendons in a horse most liable to injury and accident, are those passing down the shank bone of the fore legs, from nearly the back of the knee, to their seat of insertion at the fetlock joint, which are in general known by the name of the back sinews.

A wounded or punctured tendon, by thorn, stub, stable prong, or with any other instrument, is always attended with excruciating pain, and violent inflammation, producing the most dangerous symptoms. In such cases, it has been too much the practice to have immediate recourse to turpentine, and other spirituous applications, which is rendering the remedy worse than the disease. Warm, mild fomentations, emollient poultices, gentle digestives upon lint covered with tow, and

recourse to the most judicious and experienced practitioner to be obtained, constitute the only sound basis upon which even hope of recovery can be entertained.

**TERMS IN SPORTING.** As every sportsman, we have no doubt, feels anxious to become acquainted with the language, so, in our exemplification of sporting terms, we shall be diffuse rather than otherwise, and shall have occasion to introduce words which are become obsolete, as well as others, perhaps, which are only used in some parts of this country.

*Terms for the lodging of beasts of chase.*—A badger *earths*, a boar *couches*, a buck *lodges*, a coney *sits* or *earths*, a fox *ken-*  
*nels*, a roe *beds*, a hare *seats* or *forms*, a hart or stag *harbours*, a martern *trees*, an otter *watches*.

*Terms for dislodging them.*—To *dig* a badger, to *rear* a boar, to *rouse* a buck, to *bolt* a coney, to *unkennel* a fox, to *start* or *move* a hare, to *unharbour* a hart or stag, to *untree* a martern, to *vent* an otter.

*Their noise at rutting time.*—A badger *shrieks*, a boar *breams*, a buck *groans* or *troats*, a fox *barks*, a hare *beats* or *taps*, a hart *belleth* or *bells*, an otter *whines*, a roe *bellows*, a wolf *howls*.

*For their copulation.*—A boar goes to *brim*, a buck goes to *rut*, a coney goes to *buck*, a fox goes a *clicketting*, a hare goes to *buck*, a hart goes to *rut*, an otter *hunts* for his kind, a roe goes to *tourn*, a wolf goes to *match* or *make*.

*Terms when they are in company.*—A herd of harts and all kinds of deer, a *bevy* of roes, a *souder* of swine, a *rout* of wolves, a *richness* of marterns, a *brace* or *leash* of foxes or hares, a *couple* of rabbits or coneys.

*For the mark of their feet.*—The *track* of a boar, the *view* of a buck and fallow deer, the *slot* of a hart or red deer, of all deer, if on the grass and scarcely visible, then it is called the *foiling*; the *print*, or foot of a fox; of a hare diversely, for when she is in open field she is said to *sore*, when she winds about to deceive the hounds she *doubles*, whenever the mark of the foot can be perceived, she is said to *prick*; and in the snow her path is called the *trace*. An otter *marks* or *seals*.

*Terms of the tail.* The *wreath* of a boar, the *single* of a buck, the *scut* of a hare or rabbit, the *brush* of a fox, and the tip at the end is called the *chape*; the *single* of a stag, the *stern* of a wolf. A fox's feet are called *pads*; his head, the *front*.

*For their ordure.*—The *lesses* of a boar,

the *fewmets* of a deer, the *billeting* or *fu-*  
*ants* of a fox, the *buttons* or *crotils* of a hare, the *spraints* of an otter.

*Terms for the noises of hounds.*—When hounds are thrown off, and hit upon a scent, they are said to *challenge*. If they are too busy before they find the scent is good, they are said to *babble*. If they run it endways, making it good, and hold it on well together, they are said to be in *full cry*. When hounds hang behind, and keep too much upon a particular place, they are said to *plod* or *tye*.

When a deer turns his head against the hounds, he is said to *stand at bay*.

Of greyhounds, two make a *brace*; of hounds, a *couple*; and of greyhounds, three make a *leash*; and of hounds, a *couple and a half*: they say let *slip* a greyhound, and *throw off* a hound.

The string or cord by which a greyhound is led, is called a *lease*; and that of a hound, a *leam*, *liam*, or *lyome*.

The greyhound hath his *collar*, and the hound his *couples*.

Of fox hounds, they say a *kennel*; of harriers, a *pack*; though the word *pack* is now used indiscriminately of either one or the other.

Those places are called *entries* where they find a deer has lately passed into thickets, by which also they form an opinion of their size.

When hounds hit the scent of their chase the wrong way, they are said to *draw amiss*; that is, in drawing: as when the game is up and the hounds scent it in the opposite direction, they are then said to run the *heel* or *hunt counter*.

When hounds take a fresh scent they are said to *hunt change*.

When the chase goes off and comes on again, traversing the same ground, it is said they *hunt foil*.

When hounds kill their game, and are suffered to eat the whole or part, it is called a *reward*.

When sportsmen endeavour to find a stag by the *slot*, and examine his step, they say they know him by his *gait*.

If hounds run without making any cry, they are said to run *mute*.

When hounds chase other game than that for which they are intended, and are otherwise unruly, they are said to *run riot*.

If a hare happen to take the ground like a coney, she is said to go to *vault*.

When a fox takes to the ground, if in a regular earth, he is said to be run to *earth*; but, if in a drain or some such place, he is said to be run to *ground*.

Hounds *draw* for a fox, and *quest* for a hare.

When, in running, the dirt sticks to a hare's feet, they say she *carries*.

When hounds find where the chase has attempted to enter, but has returned, it is called a *blemish*.

When the horn is blown to collect the hounds, it is termed a *call*. It is termed a *recheat*, when the horn is blown to recall the hounds from a wrong scent. The *mort* is sounded at the death of a deer.

A hare is called, the first year, a *leveret*, the second year, a *hare*, and afterwards an *old* or *great hare*.

A fox is called the first year a *cub*, the second a *fox*, and afterwards an *old fox*.

Upon view of a stag, if he be a fine animal, he should not be called *fair*, but *great*; and so, a *great hind* and a *great buck*; but a *fair* or *comely doe*.

When a deer stops to look at any thing, he is said to *stand at gaze*; when he forceth by upon force, he *trips*; and when he runs a pace he *strains*. When he is hunted and leaves the herd, he *singles*; and when he foams at the mouth, he is *embossed*. When he swells or vents any thing, they say he hath this or that in the *wind*; when he holds out his neck at full length inclining, they say *he is spent*; and being killed, *he is done*.

The stag, buck, and boar, sometimes take soil without being forced, and all other beasts are only said to take *water*, except the otter, and he is said to *beat the stream*.

*Blemishes* are the marks to know where a deer hath gone in or out, and they are little boughs plashed or broken to hang *downwards*; for any thing that is hung up is called a *sewel*.

There is a great difference between the *frith* and the *fell*; the *fells* being taken for the *vallies*, green pasture, and *mountains*; and the *friths*, for *springs* and *coppices*.

There is also a difference between the words *ways* and *trenches*; for by the first is meant the high and beaten ways on the outside of a forest or wood; and by the word *trench*, a very small way, not so commonly used. There is likewise a difference between a *trench* and a *path*, which is a place where a deer has only left *slot* or *view*.

Of a stag and all kinds of deer, when killed, they are said to be *slain*, sportsmen say, *take off that deer's skin*. Of a hare, they say she is *stripped* or *cased*. A fox, badger, and all manner of vermin are

said to be *cased*, beginning at the snout or nose of the beast, his skin being turned over his ears down to the body till you come to the tail.

*Terms for the attire of deer*.—Of a stag, if perfect, the *bur*, the *pearls*, the *beam*, the *gutters*, the *antler*, the *sur-antler*, *royal*, *sur-royal*, and all at the top, the *croches*.

Of a buck, the *bur*, the *beam*, the *brow-antler*, the *back-antler*, the *advancer*, *palm*, and *spellars*.

If the croches grow in form of a man's hand, they are then called a *palmed-head*; three croches being placed aloft of one height, are called *crowned heads*. Heads having doubling croches, are called *forked heads*, because the croches are planted on the top of the beam like forks.

If you are asked what a stag bears, you are only to reckon the croches he bears, and never to express an odd number; for if he has four croches on his near horn, and five on his far, you must say *he bears ten*. If but four on the near horn and six on the far horn, you must say *he bears twelve*.

Of winged game, we say a *brace* of black game, or grouse, a *leash* of black game or grouse, a *pack* of black game, a *brood* or *pack* of grouse, to *raise* black game or grouse.

A *brace* of partridges, a *brace and a half* of partridges, a *covey* of partridges, to *spring* partridges.

A *brace* of quails, a *brace and a half* of quails, a *bery* of quail, to *raise* quails.

A *brace* of pheasants, a *leash* of pheasants, a *ni*, (or *nid*) or *brood* of pheasants. To *push* or *spring* a pheasant.

A *couple* of woodcocks, a *couple and a half* of woodcocks, a *flight* of woodcocks, to *flush* a woodcock.

A *couple* of snipes, a *couple and a half* of snipes, a *wisp* of snipes, to *spring* a snipe.

A *team* of wild ducks.

A *gaggle* of geese.

A *wing* of plover.

A *trip* of dottrell.

A *sege* of herons and of bitterns.

A *herd* of swans.

A *dropping* of sheldrakes.

A *spring* of teals.

A *covert* of coots.

TERRA A TERRA. In the manege, a series of low leaps, which a horse makes forwards, bearing side-ways, and working upon two treads. In this motion, a horse lifts both his fore legs at once; and when these are upon the point of descending to

the ground, the hinder legs accompany them with a short and quick cadence, always bearing upon the haunches; so that the motions of the hinder quarters are short and quick; and the horse being always well pressed and coupled, he lifts his fore legs pretty high, and his hinder legs keep always low, and near the ground. This manege is called *terra à terra*, because, in this motion, the horse does not lift his legs so high as in corvets.

**TERRIER.** It is natural enough to suppose that the terrier took his name from the avidity with which he takes the earth; particularly when in pursuit of his own game, which is vermin of every description. To the fox, badger, polecat, weasel, and rat, the terrier is the most implacable enemy. Of late years, terriers have been crossed with the bull dog, which has of course increased their strength and ferocity. The genuine terrier is employed in a business to which he seems peculiarly adapted. This is, in his subordinate attendance upon the chase. Terriers of the best blood are bred of all colours. There are also rough wire haired terriers, as well as smooth haired ones.

Few stables are to be met with without a terrier or two. Also with fox hounds, there is frequently to be seen a brace of terriers. With the hounds in endeavouring to find, as well as during the chase, their exertions are incessant and indefatigable. When a fox is run to ground, it is the province of the terrier to follow and *bay at him*; as, by the baying of the one at the other, the ear will soon be informed whether the fox lies deep or near the surface; and those who are employed in digging him out will be directed accordingly. Infidelity, sagacity, courage, as well as the most incredible endurance of fatigue and hunger, terriers are inferior to no ramification of the canine species.

An anecdote related by Mr. Hope, and well authenticated by other persons, would seem to shew that the terrier is capable of resentment when injured, and of great contrivance to accomplish it. A gentleman of Whitmore, in Staffordshire, used to come twice a year to town; and, being fond of exercise, generally performed the journey on horseback, accompanied most part of the way by a faithful little terrier dog, which, lest he might lose it in town, he always left to the care of Mrs. Langford, his landlady, at St. Alban's; and on his return he was sure to find his little companion had been well taken care of. The gentleman calling one time, as usual, for his dog, Mrs. Langford appeared before him with a woeful countenance: "Alas! Sir! your terrier is lost! Our great house dog and he had a quarrel; and the poor terrier was so worried and bit before we could part them, that I thought he could never have got the better of it. He, however, crawled out of the yard, and no one saw him for almost a week. He then returned, and brought with him another dog, bigger by far than our dog; and they both together fell on our great dog, and bit him so unmercifully, that he has scarcely since been able to go about the yard or eat his meat. Your dog and his companion then disappeared, and have never been seen since at St. Albans." The gentleman heard the story with patience, and endeavoured to reconcile himself to the loss. On his arrival at Whit-

more, he found his little terrier; and on enquiring into the circumstances, was informed that he had been at Whitmore, and had coaxed away the great dog, which, it seems, had, in consequence, followed him to St. Albans, and completely avenged his injury.

**TETTER.** Called by farriers the flying worm, or ring worm. It runs up and down the skin in different directions, from whence it receives its name. It is most commonly found on the rump, and runs down the joints of the tail: and if neglected is said to turn into a canker. It will now and then settle upon some fleshy part of the body, which will be attended with so troublesome an itching, as to make the horse rub against walls and posts, till he will bring away the hair and skin, and even tear his flesh with his teeth, if he can come at it. After all, however, this disease differs little, if at all, from the mange, and is to be cured by similar means.

**THRUSH.** In this disease, there is, in the foot of a horse, an inflammation of the sensible frog, occasioned either by contracted heels, the want of cleanliness in the part, or shoeing on erroneous principles; but most frequently the last.

The thrush may be known by a tenderness felt on pressing the frog, which is also accompanied with a discharge of matter.

The cure consists in removing the shoe, and lowering the heels so much that the frog may come in contact with the ground. After which, the horse should stand without shoes for several days; and the part should be washed two or three times a-day with a brush and soap lather, and afterwards dressed with the following ointment:

Take of Vitriol zinc,  
Armenian bole,  
Alum, of each, in powder, one ounce;  
Tar, sufficient to form an ointment. Mix.

We are to apply this on lint between the cleft of the frog, and renew it occasionally.

**TIRING.** In all cases of this kind, bleeding, a cordial ball, a malt mash, and a little nursing, seem the only means most likely to promote a speedy restoration of strength and spirits.

**TOILS.** Park nets of great strength and magnitude are so called. They are used in taking deer alive for removal from one place to another. Similar nets were formerly used for inclosing wild beasts.

**TONGUE.** The tongue of a horse is sometimes lacerated by the bit of the bridle being too narrow in the mouth piece; as also by the frequent petulant jerks of the rider. These, which are slight in the first instance, are occasionally repeated, till they become ulcers, with a slough in the middle of each. In these cases, the tongue should be held on one side, while the part is touched daily with a strong solution of borax in water, till the slough falls off; when it may be cured with equal parts of honey and tincture of myrrh, well incorporated with each other.

**TRACK** is the term used to imply the footmark of either man or beast; but, in the language of the field it admits of some deviation. We *track* a man or an ox; we *slot* a deer, we *foot* a fox, and we *prick* a hare.

**TRAIL.** A term in hare hunting, and signifies hunting a hare to her form. When hounds are thrown off, if hares are plentiful, the trail, or track by which the hare has gone to her seat, is soon hit upon by some of the hounds, which *give tongue*; they are soon joined by the rest of the pack, and thus the hare is hunted up to her seat and started.

**TRAIL SCENTS OR DRAGS.** These are formed of various articles; a slice of bacon, or a red herring, impregnated with oil of aniseed; or merely a burnt bone will answer the purpose. Any of these will lead hounds in full cry across any country over which it is directed. But to accustom hounds to a trail scent or drag is to ruin them.

**TRAINERS.** A modern trainer is a personage of the most mysterious and the utmost importance. His appearance is vulgar; but he makes up for his vulgarity in affecting a sort of semi-solemnity of aspect, which, unlike the critical conjunction of Longinus, is referable, not to the sublime, but to the arch and the ridiculous; while, with slight, but significant, nods, ornamented by sententious oracles, he endeavours to impress on the minds of others his uncommon weight in the scale of creation, and the dignity with which he moves through infinite space!

To be serious. Trainers, generally speaking, are men with scarcely preten-

sions to a common village education; but from frequent contact with men of wealth and distinction, by whom, of course, they are principally employed, and occasionally consulted, they conceive themselves beings of a very superior order, whose avocations they endeavour to convert into a profound and secret science, as impenetrable as the mysteries of Eleusis! They are superlatively ignorant for the most part; but, skilled in cunning and trick, they are very rarely over-reached in driving a bargain. Self interest is their ruling passion—this is never over-looked; and, it is not merely in swelling up a bill that they display uncommon dexterity, as they are equally adroit in the various ramifications of their suspicious calling.

The preceding observations are scarcely intended to include a class of men, who are, what I call, the domestic servants of those who keep race horses, (and who attend to the stud) at least while they continue in the employment of men of character and distinction. Further, amongst the great number of trainers at present in the kingdom, there may be found a *few* honourable exceptions.

The subject of trainers will of course present to the mind a number of strange circumstances which have taken place, particularly the affair of Bessy Bedlam, at Doncaster meeting for 1828; nor indeed am I entirely without my suspicions respecting Velocipede on the same occasion. At all events, it behoves owners of race horses to pay some personal attention to their training, and neither to allow the trainer unlimited power, nor yet be governed entirely by his suggestions, unless, indeed, such suggestions are accompanied by something like good reasoning. A trainer is always to be viewed with suspicion; and on no account would I place a horse in the stables of a trainer, who was himself the owner or part owner of a race horse. Trainers, from their very occupation, have more the means of ascertaining the qualities of horses generally than other persons: they can place their horses accordingly, to say the least of it: and therefore, whenever a trainer becomes the owner of a running horse, all confidence in his integrity must vanish.

**TRAINING HORSES.** See **RACE HORSE, TRAINING THE.**

**TRAINING DOGS FOR THE GUN.** See **BREAKING DOGS**, page 80.

**TRAMMEL NET.** See the article **NETS**, page 560.

**TRAMMELS** are a collection of side

and cross lines, having leather loops at the ends, with which horses were formerly trammelled for the operations of nicking, docking, &c.

**TRESPASS.** See the article **GAME LAWS.**

**TRIAL.** It is a custom with owners of race horses to endeavour to form some tolerable idea of the speed of their colts and fillies, before they become subscribers to large stakes. To acquire information so absolutely necessary for the regulation of future proceedings, there is only one sure and certain criterion upon which reliance can be made to avoid deception. This is to obtain a confidential trial against some horse, whose superiority upon the turf is established.

Trials between horses of superior qualifications, preparatory to their being engaged in matches or stakes of magnitude, are always considered matters of great consideration, and for which the most serious preparations are made. Upon the issue of such trials, engagements are sometimes entered into, upon the termination of which, many thousands eventually depend. It is therefore a matter of indispensable necessity, they should not only be run with the most energetic opposition, but that the superiority in speed should be fully and clearly ascertained. Trials of this description are always conducted with the utmost secrecy; for the better preservation of which, they generally take place at the very dawn of day, so soon as the lads can see to ride with safety; and these trials are considered of so much consequence at Newmarket, that if any feeder, rider, groom, stable-lad, or any other person concerned, is known to discover the result, or shall be detected in watching trials himself, or procuring other persons so to do, he is dismissed the service of his master with every stigma of disgrace, and rendered incapable of being again employed by any member of the jockey club in any capacity whatever.

**TRIPPING.** A horse which goes near to the ground, is subject to tripping against every little prominence that happens to lie in his way. Many well-bred horses, exceedingly dull and indolent in a walk, overcome with ease all those trifling impediments, when put into a more enlivening and emulative action. This imperfection always displays itself most in slow paces, which is one predominant reason why a dealer is invariably anxious to let his horse, when shewn out, be seen in a trot or gallop. Horses excellent in their

fast paces, are sometimes bad walkers; but instances are very rare, where a good walker is deficient in superior qualifications. It is a remark justified by long and attentive observation, that most thorough-bred horses are sluggish stumbling walkers; they are therefore considered dull and dangerous roadsters. Horses with upright shoulders are the most liable to stumble and fall.

TROTTLING is one of the natural paces of a horse, which, in respect to speed, is wonderfully to be improved by constant practice; and it being a favourite pace with almost every horse of common description for the purposes of the road, they are observed to enjoy it, in proportion as they excel their companions or opponents.

It is a long-standing remark, that "a butcher always rides a trotter;" and why is it? because butchers invariably make them so: they in general ride them no other pace: they all know they have the credit of "making trotters," and they are incessantly alive to the preservation of their professional reputation.

Famous trotters have undoubtedly been produced from different parts of the kingdom; but Essex, Suffolk, Cambridgeshire, and Norfolk, are said to have exceeded all others in their proportion; and this may probably with justice be attributed to those famous trotting stallions, Old Shields, Useful Cub, and Hue and Cry, who principally covered that scope of country. The celebrated trotter, Archer, was descended from Old Shields; he was a remarkably strong horse, master of fifteen stone, and the fastest trotting horse of his time; but was cruelly destroyed, by being inhumanly matched to trot upon the road sixteen miles within the hour in the midst of a very severe frost; the poor persevering animal performed it in less than fifty-five minutes; but the violent concussions sustained by the body, and the battering upon the feet by the dreadfully hard state of the road, produced symptoms which soon put a period to his existence.

A brown mare, the last proprietor of

whom was Mr. Bishop, trotted upon the Epsom road sixteen miles in fifty-eight minutes and a half, carrying twelve stone; and it was then said to have been the first time that distance had ever been trotted within the hour. In 1791, being eighteen years old, she trotted on the Essex road, sixteen miles in fifty-eight minutes and some seconds, beating a famous trotter of Mr. Green's for fifty pounds. A grey mare called the Locksmith's, trotted seventy-two miles in six hours. In 1793, a grey mare of Mr. Crocket's trotted one hundred miles in twelve hours, and had twenty minutes to spare. A five year old, son of Young Pretender, (who was got by Hue and Cry,) trotted in Lincolnshire sixteen miles in fifty-nine minutes, carrying fifteen stone.

In 1797, Mr. Dyson made a bet of 100 guineas with Mr. Fagg, that he would produce a mare which should trot upon the road between Cambridge and Huntingdon seventeen miles within the hour: the experiment was made on the 7th of August, in that year, and the mare lost by one minute and four seconds only. On the 13th of June, 1799, a trotting match was decided over Sunbury common, between Mr. Dixon's brown gelding and Mr. Bishop's grey gelding, carrying twelve stone each, which was won by the former, having trotted the eight miles in twenty-seven minutes and ten seconds. Extraordinary as these performances have been, no less entitled to recital is a bet made by Mr. Stevens, which was decided on the 5th of October, 1796, that he would produce a pair of horses, his own property, that should trot in a tandem from Windsor to Hampton Court, a distance of sixteen miles, within the hour; notwithstanding the cross country road, and great number of turnings, they performed it with ease in fifty-seven minutes and thirteen seconds. Phenomena trotted nineteen miles in an hour. The American trotters, however, excel all others—many of them can trot twenty miles within the hour.

TROUT. The general shape of trouts is rather long than broad: in several of the Scotch and Irish lakes and rivers, they grow so much thicker than in those of England, that a fish from eighteen to twenty-two inches will often weigh from three to five pounds. The trout is a fish of prey, has a short roundish head, blunt nose, mouth wide, and filled with teeth, not only in the jaws, but on the palate and tongue: the scales are small, their back is ash-colour, the sides yellow, and when in season, is sprinkled all over the body and co-

THE TROUT STREAM.

vers of the gills with small beautiful red and black spots ; the tail is broad.

There are several sorts of trout, differing in their size, (for in many of the smaller streams there are trouts that always continue small, but are very great breeders,) shape, and hue ; but the flesh of the best is either red or yellow when dressed : the female fish has a smaller head and deeper body than the male, and is of a superior flavour. In fact, the colours of the trout and its spots vary greatly in different waters and at distinct seasons, yet each may be reduced to one species. In Llyndivi, a lake in South Wales, are trout called Coch-y-dail, with red and black spots as big as sixpences ; others unmarked, and of a reddish hue, that sometimes weigh nearly ten pounds, but are ill-tasted. In Lough Neah, in Ireland, are trout called Buddaghs, which rise to thirty pounds ; and some (probably of the same species) are taken in Ulls-Water, in Cumberland, of still greater weight ; and both these are supposed to be similar with the large trout of the lake of Geneva, a fish, says Mr. Pennant, which I have eaten of more than once, and think very indifferent.

A trout taken in Llynallet, in Denbighshire, which is famous for its excellent kind, was singularly marked and shaped ; it measured seventeen inches in length, depth three inches and three quarters, and weighed one pound ten ounces ; the head thick, nose sharp, both jaws, as well as the head, of a pale brown, blotched with black ; the teeth sharp and strong, dispersed in the jaws, roof of the mouth, and tongue, (as is the case with the whole genus, except the gwiniad, which is toothless, and the grayling, which has none on the tongue ;) the back was dusky, the sides tinged with purplish bloom, both above and below the side line, which was straight and marked with deep purple spots, mixed with black. The belly was white ; the first dorsal fin was spotted ; the spurious fin brown, tipped with red ; the pectoral, ventral, and anal fins of a pale brown ; the edges of the latter white ; the tail very little forked when extended.

Some peculiar remarks upon the various sorts of trout in the northern counties of England, and of their growth and age, have been given by a very experienced angler, to the following effect :—That he does not undertake to determine whether the river and burn trout are of one species : in many points, the trout taken out of the same river and same pools will agree, and in some shall vary ; so that, if the difference were owing to the water or food, he could say nothing against their being of one species : he believes they spawn promiscuously together, are all similar in shape, in the number of their fins, and their fins being disposed in the same places. Whether the colour of the spots makes any specific variety, he leaves to the decision of naturalists ; but, in his opinion, the so much esteemed charr, both red and white, is only a meer or marsh trout, and the colour perhaps owing to the sex. In several of the northern rivers, he has taken trouts as red and as well tasted as any charr, and whose bones, when potted, have dissolved, like those of the charr. That about Michaelmas he had caught trouts of a copperish hue, without spots ; the flesh, when dressed, was like bees' wax, and well tasted : that like-

## T R O U T

wise in April he took one of these trouts twenty-eight inches long, and thick in proportion, which boiled yellow, but was equally good ; and this, he thinks, was the bull-trout mentioned by Walton, and several authors, as extraordinary both for its size and goodness, and to be found no where but in Northumberland. He records a still larger fish caught in the same river (the Cocquet) by him in September, near Brenkburn Abbey ; the length, which was nearly a yard, did not strike this gentleman so much, as the bright spots upon the lateral line ; by which it appeared to him to be an overgrown burn-trout, and neither a salmon, salmon-trout, nor the same with those two he thought were the bull-trout.

Walton mentions the Fordwich trout, taken in the river Stour, of which only one instance was ever known of its being caught by the angle : it is said to be delicious eating : one weighing twenty-six pounds, and of a most beautiful colour, was taken with a net in December, 1797 ; they grow to a large size.

Another trout in Northumberland, called the whitling, the former gentleman describes as being from twelve to twenty inches long, shaped exactly like the salmon, and being red and high-flavoured as the charr ; he has taken many of them with the fly, and with night lines, in the Tweed and the Wensbeck, but never with any spawn in them, which induced him to consider them salmon smelts, that had been to the sea and returned to the fresh water in the same summer, and which the following spring would be what is termed a gilse, or year old salmon : none of them had spots either red or black, which the burn and salmon trouts have ; but the fishermen of the Tweed flatly contradicted his suggestions by positively affirming that none were ever known to grow above twenty inches long.

The burn or river trout, he says, with plenty of food and good water, grows rapidly : several experiments were made in ponds fed by river water, and some by clear springs, into which the young fry have been put at five or six months old, (that is, in September or October, reckoning from April, when they first come from the spawning beds,) at which time they will be six or seven inches long : in eighteen months the change has been surprising : he has seen a pond drained ten months after being thus stocked, which was in July, when the fish were fifteen months old ; some were fifteen or sixteen inches, others not more than eleven or twelve : the fish were returned into the pond, and it was again drained the March following, when some were twenty-two inches, and weighed three pounds ; others were sixteen inches, and some not more than twelve. To what, asks this gentleman, can we attribute this difference ? In water, food, and weather, they all fared alike : his opinion is, that the fry were the produce of trouts of various ages, and that the older and larger the parents, the more speedy is the growth of their offspring.

In some rivers, trouts begin to spawn in October, but November is the chief month ; the end of September they quit the deep water to which they had retired, during the latter part of the hot weather, and make great efforts to gain the source of the currents, (they also swim up brooks, where they are too often destroyed by the poacher,

## T R O U T

who is always upon the watch, and is sure to cause terrible havoc at this season,) seeking out proper places for spawning: this is always upon a gravelly bottom, or where gravel and sand are mixed among stones, towards the end and sides of a stream, and in lakes, &c. where the bottoms are gravel, among weeds, where they make themselves beds and deposit their ova; (they are very prolific, and the spawn is most eagerly sought after and devoured by the grayling;) at which period they turn black about the head and body, and become soft and unwholesome; in fact, they are never good when big with roe, which is contrary to the nature of most other fish: after spawning they become feeble, their bodies wasted, and those beautiful spots, which before adorned them are imperceptible; their heads appear swelled, and the eyes dull, (and Mr. Pennant says, the under jaw is subject, at certain times, to the same curvature as that of the salmon). In this state they seek still waters, and continue there sick, it is supposed, all the winter; a prey also to vermin, which breeds upon and keeps them poor.

In March, or if mild open weather, in February, trouts begin to leave their winter quarters, and approach the shallows and tails of streams, where they cleanse and restore themselves to health: as they acquire strength, they advance still higher up the rivers, until they fix upon their summer residence, for which they generally choose an eddy, behind a stone, a log, or bank that projects forward into the water, and against which the current drives; whirlpools and holes into which sharps and shallows fall, under roots of trees, and in places shaded by boughs and bushes; in small rivers they frequently lie under sedges and weeds, especially in the beginning of the year, before their perfect strength is recovered: but when in their prime, they feed in the swiftest streams, and are often found at the upper end of mill-pools, at locks, flood-gates, and weirs, also under bridges, or between two streams running from under their arches, and likewise in the returns of streams, where the water seems to boil; in the decline of summer, they lie at mill-tails, or end of other streams, and in the deep water.

Trouts may be said to be in season from March to September; they are fattest from the middle of August until the latter month, from their having fed upon the spawn and young fry of various fish: which constitutes their firmness and flavour. Some however contend, that their prime season is in May; but in that month and in June they so glut themselves with flies, as to cause a flabbiness which they neither have at the end of April, nor at the time above mentioned.

There are few fish that afford the angler such diversion, or require more skill to take them, than the trout: (such is the passion to fish for them, that the liberty of angling in some of the streams in the adjacent counties is purchased at the rate of ten pounds per annum by the amateurs of the metropolis;) they are at all times exceedingly circumspect, and it will be in vain to angle when the water is low by being kept up at the mills, as they then retire under the banks and roots, refusing all baits. In a cloudy day, after a gentle shower,

when the mills are going, they will freely take minnows, worms, and flies of all kind in their proper season: in March or April, angle for them with the worm in the forenoon, and with a fly or minnow, according to the state of the water, the rest of the day; in the swiftest and sharpest currents, provided the day be warm and bright, and in the deeps early and late; but if the water be discoloured or very thick, try the gravelly shallows, near the sides and tails of streams, with a worm only, to run on the bottom with one large shot a foot at least from it. When there is a small fresh, or the water is clearing off, and is of a dark brownish colour, first use the worm, (which should be a well-scoured brandling, cast in as a fly at the head of the stream, and moved gently towards you, still letting it go down with the current, so as to keep it a little under water; the line should be rather short, with no lead upon it, and the hook fine,) then the minnow, and as the water clears, the artificial flies.

When the water is clear and low in sultry weather, the beetles, blue-bottle, palmer, cad-bait, wood-fly, earth-bob, &c. may be successfully used. Barker has left directions in night angling for trout, where the most killing baits are specified; his account states, that being solicited by a nobleman, who was his patron, to get a dish of trout against the next morning, he set off to the river, and describes his progress there as follows: "It proved very dark; I threw out a line of three silks and three hairs twisted for the upper, and two hairs and two silks for the lower part, with a good large hook. I baited my hook with two lob-worms, the four ends hanging as meet as I could guess them; I fell to angle; it proved very dark; so that I had good sport, angling with the lob-worms as with flies on the top; you shall hear the fish rise on the top of the water, then you must loose a slack line down to the bottom, as nigh as you can guess; then hold your line straight, feeling the fish bite; give time, there is no doubt of having the fish; for there is not one amongst twenty but doth gorge the bait; the least stroke fastens the hook, and makes the fish sure; letting the fish take a turn or two, you may take him up with your hands. The night began to alter, and grow somewhat lighter; I took off the lob-worms, and set to my rod a white palmer fly, made of a large hook; I had good sport for a time, until it grew lighter, so I took off the white palmer, and set to a red palmer, made of a large hook; I had good sport until it grew very light, then I took off the red palmer, and set to a black palmer; I had good sport, made up the dish of fish, so I put up my tackles, and was with my Lord at his time appointed for the service.

These three flies, with the help of the lob-worms, serve to angle all the year for the night, observing the times as I have shewed you in this night's work, the white fly for darkness, the red fly in medio, and the black fly for lightness. This is the true experience for angling in the night, which is the surest angling of all, and killeth the greatest trouts. Your lines may be strong, but must not be longer than your rod\*.

---

\* Night fishing with a fly is best from May to the end of August; but the largest

The rod for general trout fishing should be from fourteen to sixteen feet, the lower part of well seasoned ash or hazel, large enough to be so bored, as to hold a stiffer top for minnow and worm angling, and towards the butt-end for the reel to fasten on properly; the middle should be good yew or hickory, the top of the same nicely spliced, and about half a foot of round tortoise-shell properly lessened to the end, and the rod neatly ringed in the same manner as that for salmon; it must be regularly taper from bottom to top, with a good spring, and pliable almost to the hand for fly-fishing.

**TRUMPATOR.** A black horse, foaled in 1782; bred by, and the property of, the Right Hon. Earl of Clermont.

Trumpator was got by Conductor; his dam, Brunette, by Squirrel; grandam, Dove.

At Newmarket second October meeting, 1784, Trumpator beat Mr. Panton's Usurper, 7st. 10lb. from R. M. Post, to the Post in the Furzes, 100gs:—two to one on Trumpator.

At Newmarket first spring meeting, 1785, Trumpator won the second class of the prince's stakes of 100gs. each, h. ft. for three years old; colts, 8st. 3lb. fillies, 8st. A. F. beating Lord Egremont's brown colt, by Highflyer, out of Angelica; Duke of Grafton's Spartacus; Mr. O'Kelly's Clarionet, Lord Grosvenor's Roundelay, and Lord Derby's Inca:—two to one against Spartacus, three to one against Clarionet, and seven and eight to one against Trumpator. In the first Oct. meeting he won the Clermont stakes of 25gs. each, for 3 years old; colts, 8st. 2lb. fillies, 8st. A. F. (five subscribers,) beating Mr. O'Kelly's Butterfly, and Duke of Cumberland's chesnut filly, by Eclipse, out of Pomona:—three to one on Trumpator. In the Houghton meeting, at 8st. 7lb. he beat Mr. Bullock's Balloon, 8st. 5lb. A. F. 500gs:—seven to four on Balloon.

At Newmarket first spring meeting, 1786, Trumpator beat Lord Grosvenor's Vulcan, 8st. 7lb. each, B. C. 200gs:—seven to four on Trumpator. In the same meeting, he won the claret stakes of 200gs. each, h. ft. 8st. 7lb. B. C. (five subscribers,) beating Mr. Douglas's Rasper:—four to one on Trumpator. Next day, at 8st. he received ft. from Mr. Wyndham's Guyler, 8st. 7lb. A. F. 200gs. h. ft. On Tuesday, in the second spring meeting, he beat Lord Grosvenor's Alexander, 8st. each, B. C. 500gs:—five to four on Alexander. Same day, he received 15gs.

compromise from Duke of Grafton's Spartacus, 8st. 7lb. each, B. C. 300gs. h. ft. On Saturday, at 8st. he beat Lord Grosvenor's Premier, 5 years old, 8st. 10lb. Ab. M. 200gs:—six to four on Premier. In the second October meeting, at 8st. 6lb. he received forfeit from his R. H. the Prince of Wales's Mountebank, 8st. 8lb. A. F. 200gs. h. ft. Those were the only times of his starting that year. He started four times besides the above, and was beat, viz. at Newmarket second spring meeting, 1785, by Lord Grosvenor's Vulcan, for a sweepstakes of 200gs. each, A. F. but beat Mr. O'Kelly's Cherry. In the same meeting, for the main of the prince's stakes of 200gs. each, h. ft. A. F. by Mr. Wyndham's Guyler, Mr. Bullock's Balloon, and Duke of Grafton's Spartacus. At Ascot Heath, by Lord Grosvenor's Roundelay, for a sweepstakes of 50gs. each, h. ft. one mile, but beat Mr. Bullock's Balloon, Lord Grosvenor's Grant-ham, and Mr. O'Kelly's Clarionet. And in the first October meeting, Mr. Pleasant's grey filly, by Highflyer, dam by Match'em, for the Perram purse, D. I. but beat Duke of Grafton's Oberon, Lord Grosvenor's Alexander, Mr. Lade's Pilot, Mr. Vernon's Mousetrap, Prince of Wales' Figaro, Mr. Hale's Icarus, Mr. Panton's Wasp, and Mr. Fox's Melon.

Trumpator was a stallion at Chippenham, near Newmarket, in 1787, 1788, 1789, 1790, and 1791, at 5gs. and 5s. At Clermont Lodge, near Brandon, Norfolk, in 1792, at 15gs; 1793, at 10gs. and a half; 1794 and 1795, at 15gs. and a half; 1796, at 10gs. and a half; 1797 and 1798, at 12gs. and a half; 1799, 1800, 1801, and 1802, at 10gs. and a half; 1803 and 1804, at 8gs. and a half. At Rockingham Castle, Northamptonshire, in 1805 and 1806, ten mares besides those of his owner at 10gs. and a half. At Newmarket, in 1807, twenty mares at 16l.

fish are caught in the latter month. Trout will take in the dark nights of any of the subsequent months, provided they are soft and calm.

1808, was to have covered twenty mares, at 20gs. each, but died May 7, in that year, and was buried at the end of the Clermont course.

**TUMOURS** are preternatural enlargements in any part of the body or extremities of a horse, occasioned by external injuries, or arising from internal causes, requiring different modes of treatment, according to appearances, or the means by which they have been produced. Swellings proceeding from blows, bruises, and other accidents, are, in general, merely temporary, and submit to such cool repellents, and mild astringents, as are usually applied upon such occasions; but not submitting in a few days, a formation of matter may be suspected, and should expeditiously be promoted; for which purpose, fomentations, poultices, and patience, are the only aids required.

**TUNNEL NET.** This is a large net used by poachers for taking partridges in the night. The tunnel net was generally made about fifteen feet in length, and twenty inches deep, and was formed with two wings, so that when they were extended and fixed to the ground by pegs or stakes prepared for the business, the net formed an angle with the tunnel or flue in the middle. As a preparatory measure for the use of this net, it was necessary to ascertain, if possible, where the covey slept; which being accomplished, towards midnight, the net was placed in a particular part of the field, and a horse employed for the purpose of driving the birds into it. A bridle being put upon the horse, the poacher tucked up the skirts of his coat, and placing his right hand upon the horse's withers, was enabled thus to guide him, keeping step, at the same time, with the movement of the horse's fore legs. Thus the field was traversed till the covey was found. The off or farther side of the horse was presented towards the birds, and they, to avoid being trod upon, would move from the spot where they had taken up their quarters for the night, and run, but not take wing; for as they perceived nothing but the horse, they apprehended no further danger than being trodden under his feet. The horse was made not only to follow the birds; but he was manœuvred in such a way as to drive them towards the net, into the tunnel of which they were ultimately driven, and the whole covey thus captured. Almost any horse would answer the purpose, very little training was necessary; and, what appears strange,

many of the horses used for this species of nocturnal depredation, became extremely fond of it. The tunnel net has been in a great measure laid aside, and the more rapid, but less certain, method of the drag net substituted for it.

**TURF.** The turf, when used in a sporting sense, is intended to imply whatever appertains solely to the pleasure of horse racing, without any collateral signification whatever; custom having established three concise terms, by which the distinct sports may be fully comprehended, and the intentional meaning perfectly understood. The *sod* is known to be fully expressive of cocking; the *field*, of hunting; and the *turf*, of racing; these being the admitted technical terms of the sporting world, to which none else make the least pretensions.

Prior to the reign of James I. horse racing, though it occasionally took place, appears to have been conducted upon no regular principle; and, therefore, we may very reasonably regard the origin of the English race course as coeval with the reign of this monarch; who, in defiance of his real or affected piety, seems to have been attached to the amusements of the turf. Hence it may be presumed that horse racing in Scotland had become a regular and general diversion before the time of this prince, during whose reign, courses were formed and prizes were run for in various parts of this country, particularly in Yorkshire; and also at Croydon and Enfield.

“The first Arabian, which had ever been known as such in England, was purchased by the royal jockey, of a Mr. Markham, a merchant, at the price of five hundred pounds.—That illustrious master of the science of equitation, the Duke of Newcastle, in his treatise, describes this Arab as a little bay horse, of ordinary shape, and judges he was good for nothing, because, being trained and started, he could not race, but was beaten by every horse which ran against him. As to the wonder expressed that Arabian horses should not have been brought earlier into England, it is merely perhaps that the name was omitted, as Arabs were generally sold in those markets of the Levant, where horses were purchased for Europe; and there can be little doubt that the Arabian breed was dispersed throughout Europe, centuries previous to the reign of James.”

The diversions of the turf were well adapted to the taste of the English; and

although Charles I. paid less attention to them than his father, the passion for racing was cherished during the domestic troubles of this prince's reign, and even the wily, but industrious, Cromwell, found time to pay some attention to the improvement of the breed of running horses. Mr. Place, his master of the stud, was proprietor of the famous White Turk, as well as of several very superior brood mares, one of which was afterwards known by the name of the Coffin Mare, from the circumstance of the animal being concealed in a vault, during the search for Cromwell's effects at the time of the restoration.

Charles II. was much attached to the amusements of the race course : this monarch gave public prizes, and regularly entered horses in his own name. He also despatched his master of the horse to foreign parts, for the purpose of purchasing brood mares and stallions. James II. was also attached to the turf; and the most favourite stallions during the reigns of the princes just mentioned, were the Helmsley Turk; Dodsworth, a barb, foaled in England; the Taffolet Barb; the Lister Turk; and the White-legged Lowther Barb.

William III. a soldier from inclination, encouraged horse racing : during his reign, the Oglethorpe Arabian and the Byerley Turk were introduced as stallions to the notice of the sporting world, as well as several other horses of minor importance.

The reign of Queen Anne, though principally occupied in the vigorous prosecution of a very bloody war, was, nevertheless, highly favourable to the successful progress of the Turf. Her consort, Prince George of Denmark, was much attached to horse racing, and kept a fine stud. During this reign, the stallions most in repute were Croft's Bay Barb, the Curwen Bay Barb, the Leeds and Woodstock Arabians, the Honeywood White Arabian, Cole's Barb, St. Victor's Barb, and, above all, the celebrated Darley Arabian.

George I. appears to have felt but little interest in the proceedings of the turf; yet in the latter part of his reign, cash was substituted for the royal plates, which system, far preferable to that which preceded it, has continued to the present day.

George II. paid but little attention to horse racing, though in the 13th year of his reign, an act was passed for the suppression of pony races, or running small and weak horses; and by this act it was

also forbidden to race for less than fifty pounds.

His Royal Highness the Duke of Cumberland, great uncle to his present majesty, was not merely an amateur of the turf, but a warm patron of horse racing, and a great breeder; indeed, it may be justly observed, that, in the last particular, he spared neither pains nor expense, and ultimately produced the best race horse the world ever saw, the celebrated Eclipse, though the Royal Duke did not live to witness his unrivalled performances.

Horse racing had never so numerous a list of supporters as at the present moment, many of whom are persons of immense wealth, as well as of eminent rank and distinction.

His late majesty spared no expense in the purchase of the best horses that appeared on the turf; and from the splendid patronage which he afforded to horse racing, it was evident that he was deeply sensible of the national benefit thence arising, not merely on account of the money thus put into circulation, but from the important circumstance of possessing a breed of horses vastly superior to what can be found in any other part of the world.

Generally speaking, however, the proceedings of the turf would seem to partake too much of business-like transactions, or a system of trade, not in regard to betting, and other collateral circumstances necessarily connected with the course, but as far as respects the horses. Racers are now exhibited for prizes, in public, at a much earlier period than formerly, and it requires no great stretch of credulity to suppose, that, in this way, many modern Eclipses have been ruined while in an incipient state. The celebrated Eclipse never contended on the race course till he was five years old, and to this circumstance may unquestionably be attributed some share of that unrivalled fame which he afterwards acquired as a racer: had he been put to those desperate exertions at two years old, which is so much in fashion at the present day, there is very great reason to believe, that it would have seriously injured, in embryo as it were, those amazing powers, the perfection of which he exhibited with such unparalleled success. The horse, it is very well known, does not attain his full growth and powers till he arrives at the age of seven; till this period, his bones have not acquired their natural

solidity, his sinews or ligaments their elastic force, his muscles that depth, expansion, and firmness, which denote the maturity of this most elegant quadruped in the almost unbounded catalogue of nature: consequently, till this consummation of the aggregate powers of the racer, we have no right to expect the perfection of his performances.

But, to speak as a tradesman on the subject, I must admit, in the first place, that the race horse is an expensive article, and therefore the sooner he is brought to work, the sooner he is likely to repay the money which has been expended upon him: such at least is the calculation. If a horse, at the early age of two years, give promise of future success, he will, of course, sell for a price accordingly. On the contrary, should his performances, at this period, be very unsatisfactory, his owner can avoid any further expense in training, and the animal may be disposed of for some other purpose. However, in a philosophical point of view, such a system is very inconclusive; nor have I the least doubt, that many good, indeed excellent, horses have been lost to the course in consequence of it. A young horse, two years old, for instance, (as I have already observed) is frequently so

overstrained by his first essay, (short as the distance may be, and the weight light,) that his powers never after regain their proper tone and vigour. And, indeed, how often has it happened, that the winner of the Doncaster St. Leger, though a three-years-old, owing to the very severe exertions he has undergone, has been able to shew the same extraordinary powers afterwards?—Moreover, if a horse be what is called *large for his years* or age, he will necessarily be weak by comparison, and therefore utterly unable to shew to any advantage in such precocious exertions as it is the present fashion to require.

If, however, the racer is, at present, introduced to the course at too early a period of his life, he is not subjected to run those unreasonable lengths or distances, nor to carry those heavy weights, which seem so much to characterise what, for the sake of distinction, may be called the old school. 'Twelve stone, and four-mile heats, were common occurrences formerly; a system which, like most other old systems, has been superseded by what may be called the progress of improvement, and is never likely to be revived. — From that interesting little book, *Brown's Turf Expositor*.

## U

**ULCER.** An ulcer is a wound, which, from long standing, and injudicious treatment, is become virulent and inveterate; having acquired a callosity at the edges,

and a discoloured, foul, unhealthy slough in the middle. It must be subdued by superficial scarification, and the milder class of corrosives and caustic applications.

## V

**VENERY** (Beasts of). The hart, hind, hare, boar and wolf.

**VENOMOUS BITES.** See **DISEASES OF DOGS.**

**VERDERER.** Is a judicial officer of the king's forests, elected (under his majesty's writ) by a majority of votes in a convened county court of the shire in which the forest is situated; and there sworn before the sheriff to keep and maintain the assizes and laws of the forest; and also to review, receive, and enrol, all the attachments and presentments, of all manner of trespasses of the forest in respect to vert and venison.

The official department of a verderer bears great similitude to that of a coroner; that, as a coroner, upon the notice of a sudden or accidental death (if attended

with circumstances to render the inquiry necessary) is to take a personal view of the body, and to make inquiry, upon the joint oaths of twelve men, how and by what means the person came by his or her death, and who and what was the occasion thereof; so it is the official duty of the verderer to look after and view the beasts of the forest; for any of those being found hurt, wounded, or slain, upon notice given to the verderer, he is to take a view of the same, and to cause a jury of twelve men to be summoned from the surrounding district, that an inquiry may be made to discover (if possible) how and by whom the said beast was hurt, wounded, or killed. The office of the verderer at the court of attachments is to sit there to see, hear, and ex-

amine, the attachments of the forest, both in vert and in venison, and to receive the same of the subordinate officers, or those who may attend to present them there, and then to enter them into their own rolls. See the article FOREST LAWS.

VERMIN. This term includes the fox, the badger, the martern, the polecat, the wild cat, the weasel, the stoat, &c.

VERT. This is a term in the forest laws, meant to include every plant growing within a forest or its purlicus, bearing a *green leaf*, and of sufficient magnitude to hide or cover a deer beneath its branches; but it must also be understood to signify such plants as are either trees, woods, bushes, or underwood; not, however, descending to inferior shrubs, passing under the denomination of plants, but affording no cover. By *vert* is therefore implied those trees of growth and size sufficient to be entitled conjunctively to the appellation of covert; as well underwood as great wood; and overt-vert is all sorts of high trees, as nether-vert includes every kind of underwood.

VICE. The imperfections so called in a horse, are the distinguishing traits of an innate bad temper, or habit mischievously inclined: these are very different from the little airs of skittishness, and proofs of playful spirit, which are displayed by many horses, when brought from confinement to enjoy the comforts and healthy advantages of air and exercise; or others who afford the same indications of pleasure during the ceremony of dressing in the stable, horses naturally vicious and untractable seldom keep that propensity long concealed; it generally begins to appear early, and in most cases, with colts, even before they are taken in hand to break. This tendency in some is soon obliterated by gentle treatment, and frequent attentions of tenderness; but with others it continues invincible, and occasionally shews itself during the whole period of their existence. Some are constantly disposed to kick or bite in the stable, who have no one imperfection without; on the contrary, others, who are most incorrigibly restive and unruly without, shall be incredibly calm and quiet within.

Opinions opposite to each other have always prevailed upon the treatment necessary and proper with horses of this description. That authority must be enforced, fortitude exerted, patience persevered in, and submission obtained, are all positions too firmly admitted, and acqui-

esced in, to admit of contrariety; but experience has fully demonstrated, that great points are sometimes effected by the salutary interposition of equanimity and moderation, that never could be accomplished by the frequently destructive gusts of inconsiderate passion and unmanly violence. If a horse, disposed to be restive, is addicted to running backwards, the best and only remedy is to continue backing him (if there is room for the experiment) till he becomes completely averse to his own undertaking; or procuring a person to come suddenly upon him behind, during his retrograde motion, with a complete flagellation from a cart or hunting whip, which seldom or ever fails to set such a one running from the effect of fear, and to produce a complete eradication.

Horses rearing up on end, so as to stand nearly perpendicular upon their hind legs, is the most dangerous of any description, even to the most judicious, expert, and experienced horseman; who has, in such awkward predicament, (particularly when a horse most viciously repeats it) no alternative, but to slacken his reins, and lean his body close to the neck, the better to expedite so critical a preponderation. Horses inclined to run away, from an impetuosity of temper, and an eagerness to get forward, frequently alarm their riders, if they are exceedingly irritable upon the score of timidity, or terrified upon the principle of inexperience; but sportsmen mostly prefer horses that require the curb to those who want a spur, well knowing the utility of moderately dropping the hand, and indulging the loose occasionally; as a dead pull at a hard mouthed run-away horse, is the sure means of making him endeavour to continue his career the longer.

VIPER BITE. See DISEASES OF DOGS.

VIVES is a disorder similar to the strangles; with this difference only, that in the strangles the tumefactions are centrally situated in the concavity of the under jaw, just below the gullet; and in the vives, the swellings are seated at the roots of the ears, descending more or less towards the neck. These differ in different subjects, as in some they do not suppurate; but by warmth, and emollient unguents, applied twice or thrice a day, are absorbed into the circulation, and are then to be taken out of the habit by a gentle course of mercurial physic; but where the swelling and inflammation are

evidently too great for repulsion and absorption, suppuration must be promoted by the means described, and the case

treated as may be found under the head STRANGLES.

VIXEN. A cub or bitch fox is so called.

## W

**WADDING.** This article at first view appears superficial, or of trifling importance; but this is not exactly the state of the case, as a little examination will convince the reflecting sportsman, that, in using proper wadding, his diversion is not only promoted, but his personal safety rendered much more secure, particularly where a double gun is used, and single guns are seldom seen at the present day in the hands of sportsmen. Where the old wadding, *paper*, is still made use of, the charge in the second barrel of a fowling piece, is very liable to become loose from the repercussion attending the discharge of the first, especially when the barrels, from repeated firing, or other causes, have been rendered foul; and when the shot is not properly secured, the barrel is always very liable to burst. Wadding punched from common card, or from an old hat, will very well answer the purpose, but those articles are inferior to soft milboard about the thickness of three cards. If cork were so cut as to fit the calibre of the fowling-piece (it cannot be punched,) there is little doubt but it would be superior to any other kind of wadding; but in this case, the assistance of a regular cork cutter would perhaps be required. The thick soft milboard is preferable to any wadding ever used by the writer; though an old hat, if clean, forms an excellent substitute.

**WALK.** One of the paces of a horse. It is the slowest and least raised of all, and performed, as any one may observe, by the horse's lifting up his two legs on a side, the one after the other, beginning with the hinder leg. Thus, if he leads with the legs of the right side, then the first foot he lifts is the far hind-foot, and in the time he is setting it down, (which, in a step, is always short of the tread of his fore-foot on the same side) he lifts his far fore-foot, and sets it down before his near fore-foot. Again, just as he is setting down his far fore-foot, he lifts up his near hind-foot, and sets it down again just short of his near fore-foot; and just as he is setting it down, he lifts his near fore-foot, and sets it down beyond his far fore-foot. This is the true motion of a horse's legs in a walk.

**WALL-EYES**, in a horse, are those in which the iris is of a very light grey colour. These are not deemed handsome; but Gibson says, that horses which have wall eyes are generally good.

**WARBLE** is a small hard tumour, produced upon the side or the back of a horse, by the heat and friction of an ill-fitted saddle. It is sometimes occasioned by the pad of the saddle becoming exceedingly hard. Upon their first appearance, they never fail of submitting to a plentiful bathing of hot vinegar, followed by a gentle friction with camphorated spirits, if twice or thrice repeated; but if they are neglected in the first instance, and the same saddle (or harness) persevered in without alteration, the surface will become an eschar, and ultimately a sitfast.

**WARRANTY** is the assurance the purchaser of a horse receives from the seller, at the moment of terminating the bargain, if such purchase absolutely takes place, that the horse in question is no more than a certain number of years old, (as the case may be;) that he is perfectly free from every kind of vice, blemish, and defect; that he is completely sound, "wind and limb;" or, in other words, that he is in a state of perfection.

**WARREN**, is the name of a privileged place, by prescription or grant from the king, in which to keep beasts or fowls of warren. These in ancient records are said to be, the *hare*, the *coney*, the *pheasant*, and the partridge; but the word now principally applies to any particular district, or tract of land, set aside entirely for, and appropriated to, the breeding and preservation of rabbits as private property.

These become a most valuable and profitable stock. But to consider this subject according to its original intention, it may be remarked, that there is a distinction between a **WARREN** and **FREE WARREN** (which see.) The franchise next in degree to a park is a free warren, and appertains chiefly to the killing game within its boundaries. Those who possess a right of *free warren* over any particular manor have a property in the game, though it may be fed and killed upon land which is the property of another person, sup-

BIRDS, ETC. *Plate VIII.*

WARTS are spongy excrescences, sometimes appearing upon different parts of the body, and in great numbers. Moistening their surface once in three days, with butter of antimony, will effect certain ob-

literation, without the least inconvenience, even upon the eye-lids, which are of equal or superior irritability with any other part of the body.

**WATER-HEN AND THE COOT.** Before we enter upon water fowls, properly so called, two or three birds claim our attention, which seem to form the shade between the web-footed tribe and those of the crane kind. These partake rather of the form than the habits of the crane; and, though furnished with long legs and necks, rather swim than wade. They cannot properly be called web-footed; nor yet are they entirely destitute of membranes, which fringe their toes on each side, and adapt them for swimming. The birds in question are the water-hen and the bald coot.

These birds have too near an affinity not to be ranked in the same description. They are shaped entirely alike, their legs are long, and their thighs partly bare; their necks are proportionable, their wings short, their bills short and weak, their colour black, their foreheads bald and without feathers, and their habits entirely the same. These, however, naturalists have thought proper to range in different classes, from very slight distinctions in their figure. The water-hen weighs but fifteen ounces, the coot twenty-four. The bald part of the forehead in the coot is white; in the water-hen it is of a beautiful pink colour. The toes of the water-hen are edged with a straight membrane; those of the coot have it scalloped and broader.

The differences in the figure are but slight, and those in their manner of living still less. The history of the one will serve for both. As birds of the crane kind are furnished with long wings, and easily change place, the water-hen, whose wings are short, is obliged to reside entirely near those places where her food lies: she cannot take those long journeys that most of the crane kind are seen to perform; compelled by her natural imperfections, as well perhaps as by inclination, she never leaves the side of the pond or the river in which she seeks for provision. Where the stream is selvaged with sedges, or the pond edged with shrubby trees, the water-hen is generally a resident there: she seeks her food along the grassy banks, and often along the surface of the water. With Shakspeare's

## W A T E R - R A I L

Edgar, she drinks the green mantle of the standing pool; or, at least, seems to prefer those places where it is seen. Whether she makes pond-weed her food, or hunts among it for water insects, which are found there in great abundance, is not certain. I have seen them when pond-weed was taken out of their stomachs. She builds her nest upon low trees and shrubs, of sticks and fibres, by the water side. Her eggs are sharp at one end, white, with a tincture of green, spotted with red. She lays twice or thrice in a summer; her young ones swim the moment they leave the egg, pursue their parent, and imitate all her manners. She rears in this manner two or three broods in the season; and when the young are grown up, she drives them off to shift for themselves.

As the coot is a larger bird, it is always seen in larger streams, and more remote from mankind. The water-hen seems to prefer inhabited situations: she keeps near ponds, moats, and pools of water near gentlemen's houses; but the coot keeps in rivers and among rushy-margined lakes. It there forms a nest of such weeds as the stream supplies, and lays them among the reeds, floating on the surface, and rising and falling with the water. The reeds among which it is built keep it fast, so that it is seldom washed into the middle of the stream. But if this happens, which is sometimes the case, the bird sits in her nest, like a mariner in his boat, and steers with her legs her cargo into the nearest harbour: there, having attained her port, she continues to sit in great tranquillity, regardless of the impetuosity of the current: and though the water penetrates her nest, she hatches her eggs in that wet condition.

The water-hen never wanders: but the coot sometimes swims down the current till it even reaches the sea. In this voyage these birds encounter a thousand dangers: as they cannot fly far, they are hunted by dogs and men; as they never leave the stream, they are attacked and destroyed by otters; they are preyed upon by kites and falcons; and they are taken in still greater numbers in weirs made for catching fish; for these birds are led into the nets while pursuing small fish and insects, which are their principal food. Thus animated nature affords a picture of universal invasion! Man destroys the otter, the otter destroys the coot, the coot feeds upon fish, and fish are universally the tyrants of each other!

**WATER-RAIL**, although a shy and solitary bird, is sufficiently common in this kingdom, but it is only seen during the winter in the northern parts. It is found chiefly on the edges of ponds and rivulets, much overgrown with sedges, reeds, and other coarse herbage, among which it may find shelter on the appearance of an enemy, and also feed in secret security: it runs, occasionally flirting up its tail, through its tracks with similar swiftness to what the land-rail exerts in the meadows and corn-fields; and also shows an equal aversion to take flight as that bird does; and possesses more means of disappointing the sportsman, whose patience it generally exhausts, and distracts his dog, seldom rising until after it has crossed every pool, and skulked through every avenue, within the circle of its retreats; when once flushed, it is, however, easily shot, flying very indiffer-

ently, and with its legs hanging down: it will, at times, take to the water, swimming tolerably well, and is often seen running on the surface, where there are any weeds to bear it up.

The eggs of the water-rail, according to Latham, are more than an inch and a half long, of a pale yellowish colour, marked all over with dusky brown spots, nearly equal in size, but irregular. The flesh is of a delicious flavour.

The length of the water-rail is twelve inches, breadth fourteen, and weight three ounces and a half; the bill is slightly curved, one inch and three quarters long, of a dusky black colour, but reddish at the base; irides red; the top of the head, hinder parts of the neck, back, scapulars, coverts of the wings, and tail, are black edged with dingy brown; the under parts, from the chin to the middle of the belly, ash colour; in some, supposed to be young birds, margined with white; the side feathers are beautifully crossed with black and white, and slightly tipped with reddish brown; the inner side of the thighs, the belly, and the vent, are pale brown, sometimes specked with blueish ash-colour; under tail coverts white; quills dusky; the tail consists of twelve short black feathers, edged and tipped with dusky red; some of those on the under side barred with black and white. The legs, which are placed far behind, dusky red; the toes long, and without any membrane to connect them.

The water-rail is found in Lancashire, and the northern parts of England, and is plentiful in the marshes of Sweden, Norway, Russia, and in the western part of Siberia, and throughout the continent of Europe; from whence, during the severity of winter, it migrates southward, even into Africa. Buffon says, they pass Malta in the spring and autumn; and in confirmation adds, that "the Viscount de Querheint saw a flight of them at the distance of fifty leagues from the coasts of Portugal, on the 17th of April, some of which were so fatigued that they suffered themselves to be caught by the hand."

**WATER SPANIEL.** The dog which passes under the denomination of the water spaniel is not so common as formerly. He is generally of the middle size, with a rough curly coat, and in fact too well known to need a particular description. In wild-fowl shooting, they are useful in fetching the killed or wounded bird out of the water; and it is in matters of this sort that they are principally employed.

**WATERING.** In the language of the stable, the supplying horses with water at stated times. The properties of water as a suitable diluent of solid food are well known: but it is a matter of some consequence to be certain that the water given to animals is pure and uncontaminated with unwholesome particles, either in a state of simple mixture or of chemical union. That water may hold in solution many deleterious ingredients has been shewn and the subject has been thought of so much im-

portance by Mr. Clark of Edinburgh, as to induce him to treat of it in a separate chapter, in which he not only considers the diseases that horses are liable to from the constant use of unwholesome water, but also makes some judicious remarks on the management of horses, with regard to the hazardous practice of indulging them in drinking it cold, at improper times, or to a dangerous excess.

Water, says he, is the main diluter of the food and fluids in general. It likewise

becomes the vehicle of all nourishment to the animal. On that account, we cannot be too curious about its qualities, nor delicate in our choice of it for our horses, as it partakes of the qualities of those bodies which it passes through. Whether they are metallic, saline, or earthy, &c. these foreign matters mix with the animal fluids, according to their different gravity, and the capacity of the canals through which they circulate, and will, by the laws of motion, be deposited on one part or other.

As the proportion of water which enters into the composition of animal fluids is considerable, so likewise is the proportion of fluids secreted. A large quantity of water diffused through the whole mass of fluids in the body, adds to its fluidity. Hence it will be obvious that constant and frequent supplies of water are not only necessary to dilute the food in the stomach, but the mass of fluids in general; as they, even in the most healthy state, have a constant tendency to putrefaction, and require constant supplies both of food and drink to keep them in a healthy condition.

Those who have searched into the causes of disease in the human body, allege that some of the most obstinate of the chronic kind proceed, in a great measure, from the use of unwholesome water; and, by comparing the different strata of earth through which water passes about populous cities, they affirm, that, where the water is bad, those diseases prevail most. It is likewise thought that the disposition to gravel in the urine may be owing to the same cause. In like manner, water which contains mineral bodies, and metallic salts, is thought to enlarge the glands of the throat and jaws; and hence it is said, that the inhabitants about the Alps, &c. where the waters abound much with these qualities, are much disposed to glandular obstructions, and other serious maladies. These circumstances seem to warrant the conclusion, that those waters are not digestible, or that they do not assimilate or mix intimately with the fluids; and hence prove the source of calculous concretions, and of hard swellings, in different parts of the body.

The effects of unwholesome water upon the human body being thus evident, if the diseases of animals, particularly those of horses, were as thoroughly investigated, it is more than probable that they would be found equally hurtful to brute animals; for it is certain that they are subject to

diseases which, in many respects, resemble those of the human body. We likewise find, upon dissecting their bodies, that they are subject to calculous concretions, and hard tumours, in different organs, and which may originate from the source we suspect.

Here our author adduces some proofs of the existence of urinary calculi in horses and quotes the opinion of Bracken, who, in his second volume of "Farriery Improved," when treating of the gravel, says, "But the greatest cause of it (in my thoughts) is owing to their drinking such waters as, by running through the various strata of earth, are impregnated with stony particles. In short, whatever can bring on an accumulation of earthy, or rather tartareous, matter, in the urinary passages, whether by obstructing or lessening the capacity of the canals, or by immediately or remotely producing the substance itself, will cause gravel, and in time the stone."

"It has frequently been observed," continues Mr. Clarke, "that horses do not thrive on changing from one part of the country to another, although their treatment, in every respect, be the same, the difference of water excepted. This perhaps, may, in a great measure, be owing to the quality of the water they drink, and which may be possessed of different qualities from that to which they had before been accustomed. This is particularly observed in those places where the stable yards are supplied from pit-wells, some of which are very deep, and the water very hard, which occasions that chilliness, trembling, and shaking, which frequently is observed in horses when they drink it immediately after it is new pumped, and which causes their coats to stare, and stand on end, for a considerable time, and sometimes they are griped, and seem greatly out of order.

Spring-water is liable to partake of all the metalline or mineral strata through which it passess. Hence it becomes noxious or salutary, according to the nature of those substances with which it has been in contact.

River-water has likewise its different qualities from the various soils through which it travels; but, in general, it is much softer than water that runs under ground, and therefore much fitter for use.

Well or pit-water is subject to all the inconveniences of spring-water, with this additional circumstance, that it is gener-

ally hard, and, by stagnating long in the well, it may there take up from the bed it lies upon such particles as may render it more unwholesome; therefore the goodness of all well or pit-water is to be doubted, and particularly that which is taken from very deep wells.

Pond-water (under which head may be included all stagnant waters, which generally proceed from rain), if lying on a clean or clayey bottom, and fresh, answers very well for cattle of all kinds; but, in warm weather, it is apt to corrupt and ferment, which renders it unwholesome, and the most uncleanly and disagreeable of any."

Mr. Clarke is inclined to prefer, upon the whole, those waters "that are lightest, and most readily break soap," as these easily digest and assimilate with the fluids of the animal.

"To correct the hardness of pit-water, and render it more salutary for horses to drink," he says, "it should be pumped into a large trough, and exposed to the open air for some time before it is used; or, if a cart-load or two of clay or chalk were thrown into the well, it would greatly improve the water. It has likewise been found, that breaking down a piece of clay, about the size of an apple, in a pailful of hard water, before it is given to horses for drink, morning and evening, has produced a considerable favourable change on the coats of horses. Indeed it will be found, that, where horses are obliged to drink hard water, they are, for the most part, rough-haired, and at the same time, they will have a great deal of dusty matter at the roots of it, even although they should be well curried and frequently brushed; which plainly shows that there is some obstruction of the pores of the skin, which prevents the natural perspiration, and, of course, that shining appearance of the hair, which is observed in all horses that perspire freely. Hence it would appear that this cutaneous obstruction proceeds from the constant drinking of water of a bad quality.

Water that is transmitted through limestone, although exposed to the open air in large ponds, will retain its hardness, and produce all the effects above mentioned on horses that drink it constantly. This was observed at a nobleman's seat near Edinburgh. On mentioning the above circumstance, accidentally, to a great breeder of cattle, from the north of England, he advised the throwing some cart-loads of clay into the pond, which produced a consider-

able change on the water for the better.

When pit-water is rendered impure, from stagnating too long, without being drawn off by pumping, or when it has acquired any bad smell, by filth getting into it, or full of animalcula or small earth-worms, throwing into the well a few shovels-full of burnt lime will render it sweet and fit for use.

Horses have a delicate taste and smell, and are very nice in the choice both of what they eat and what they drink; of course, they shun, when it is in their power, every thing that is disagreeable to their senses. But when they are long restricted from drinking water, they will, in that case, offend their taste to assuage their thirst. This is evident from their readily drinking water strongly impregnated with nitre, or with quick-lime, in certain cases, when these are given as medicine. But this restriction ought never to be laid on horses, more especially when they are labouring under any inflammatory diseases; as, in such cases, they cannot drink too much, in order to dilute their blood and promote their natural secretions. But it too frequently happens, through mismanagement, that they are forced, from necessity, to drink water which they loath, and that, of course very sparingly; when, at the same time time, if given them in a proper manner, and of a proper temperature, it might prove in many cases, the best medicine they could have.

Horses should never be suffered to drink too much cold water at one time. If they are disposed to this, it shows that they have been neglected in this respect; for, if they had always water at command, they would drink often, but never too much at once. For this reason, water should be offered them frequently, but not in too great a quantity. Neither should they be allowed to drink much water when they are going to perform any active exercises, as has been noticed in another place. See MANAGEMENT.

It is, however, very refreshing to horses to allow them to wash their mouths and throat by a glut or two of water, after performing any severe exercise; but they ought on no account to be indulged in drinking a quantity of cold water when they are overheated. This should be particularly guarded against, as the consequences are dangerous, and frequently prove fatal to them; for, when a quantity of cold water is taken into the stomach in this heated state, when its vessels are full,

and distended with blood, a stagnation of the blood in these vessels takes place, a mortification follows, and death ensues; therefore, when a horse has been overheated, from exercise, &c. small quantities of water should be given him at a time in a pail, but not till he appears to be thoroughly cooled. In very cold weather, indeed, the chill should be taken off, by mixing the water with some which has been heated. In these cases, it is likewise of service to add to it some oatmeal or bran."

The too common practice of riding horses hard after they have drank water, in order (as the phrase is) to warm it in their bellies, Mr. Clark, very properly, condemns; but walking or trotting gently, he thinks, may be of use. In travelling, towards the end of the stage, if a horse is not too warm, it is very proper, if an opportunity offers, to give him a little water, but by no means to suffer him to drink so great a quantity as to endanger internal inflammation.

To the cautions of the judicious writer from whom we have quoted, we are inclined to recommend that of avoiding the use of water that has stood long in a leaden cistern. It is well known that horses are extremely subject to cholic; and as water is very liable to unwholesome impregnation from lead, the latter may be, and no doubt frequently is, the actual, though unsuspected, cause of that malady.

WAXY was a horse of considerable reputation upon the turf, and whose performances rendered him a stallion of high estimation. He was bred by Sir F. Poole; foaled in 1790; got by Pot80's out of Maria, a daughter of Herod. In 1793, when three years old, he won the Derby Stakes (at Epsom) of 50gs. each, half forfeit, (50 subscribers,) beating twelve; the remainder paying forfeit. The odds

twelve to one against him at starting. At Lewes he won a sweepstakes of 10gs. each, (9 subscribers,) carrying 7lb. extra. At Abingdon he won a sweepstakes of 10gs. each, 5 subscribers. In 1794, he won the Jockey Club plate at Newmarket; the King's 100gs. at Ipswich; a 50l. plate, and 60gs. at Lewes. In 1795, the King's plate at Salisbury. In 1796, the King's plate at Guildford; a subscription of 10gs. each, (13 subscribers,) at Lewes; and the King's plate at Salisbury. In 1797, he broke down in running for the gold cup at Oxford. The following season he was announced as a stallion, at 10 guineas a mare, and half a guinea the groom, at Lewes, in Sussex.

WEANING is the act of separating a colt or filly from its dam; and must always become dependent upon circumstances, in respect to the kind of country in which the colt is produced, as well as the purpose for which he is bred, and the late or early part of the season in which he was foaled. A foal produced at the latter end of April, or the beginning of May, will better bear weaning in the early part of October, than a foal dropped in June will in two months after. Where the foal, from having fallen late in the year, or any other cause, is observed to be weak in body and constitution, or stunted in growth, great advantage may be obtained by letting him run in an unrestrained state with the dam during the remainder of the winter.

At whatever time weaning may be determined on, the transition from one food to another so exceedingly opposite, should not be too suddenly made; the salutary interposition of mashes, made from ground malt and bran, and thin in consistence, will prove a pleasing and consolatory assistance for the loss the foal has sustained.

WEASEL.—The hare has no enemy more fatal than the weasel, which will follow and terrify it into a state of absolute imbecility, when it gives itself up without resistance, at the same time making piteous outcries. The weazel seizes its prey near the head; the bite is mortal, although the wound is so small, that the entrance of the teeth is scarcely perceptible; a hare or rabbit bit in this manner is never known to recover, but lingers for some time and dies.

The common weasel is the least animal of this species; the disproportionate length and height of the little animals which compose this class are their principal characteristic, and are alone sufficient to distinguish them from all other carnivorous quadrupeds. The length of the wolf in proportion to its height is as one and a half to one:

## W E A S E L

that of the weasel is nearly as four to one. The weasel never exceeds seven inches in length, from the nose to the tail, which is only two inches and a half long, it ends in a point, and adds considerably to the apparent length of the body. The height of the weasel is not above two inches and a half, so that it is almost three times as long as it is high. The most prevailing colour is a pale tawny brown, resembling cinnamon on the back, sides, and legs; the throat and belly white; beneath the corners of the mouth, on each jaw, is a spot of brown; the eyes are small, round and black; the ears broad and large, and, from a fold at the lower part have the appearance of being double: it has whiskers like a cat, but has two more teeth than any of the cat kind, having thirty-two in number, and these well adapted for tearing and chewing its food. The motion of the weasel consists of unequal bounds or leaps, and in climbing a tree it gains a considerable height by a single spring from the ground: in the same precipitate manner it jumps upon its prey, and, as it possesses great flexibility of body, it easily evades the attempts of much stronger animals to seize it. We are told that an eagle, having pounced upon a weasel, mounted into the air with it, and was soon after observed to be in great distress; the little animal had extricated itself so much from the eagle's hold, as to be able to fasten upon the throat, which presently brought the eagle to the ground, and gave the weasel an opportunity of escaping. This however is somewhat unlikely, as the distance from the eagle's claws to its throat, when flying, would be farther than the largest weasel could reach.

The activity of the weasel is remarkable; it will run up the sides of a wall with such facility that no place is secure from it. The weasel always preys in silence, and never utters any cry, except when it is struck, when it expresses resentment or pain by a rough kind of squeaking. It is useful to the farmer in winter by clearing his barns and granaries of rats and mice; more slender and more nimble than the cat, it presents a more deadly foe, as it can pursue the former into its hole, where their destruction is certain to follow. Into the pigeon house, it is sometimes a most unwelcome intruder, as it spares neither eggs nor young ones. In summer it ventures to a distance from its usual haunts; is frequently found by the side of water near corn mills, and frequently follows wherever a swarm of rats occupy any place.

The female brings forth in the spring and takes great pains for the comfort of her young, by preparing a bed for them of moss or some warm soft material. They have from three to five at a litter, which are born blind, but they soon acquire both sight and strength to follow their dam in her excursions.

This animal sleeps in its hole during the greater part of the day, and the evening is the chief time when it commences its depredations; it then may be seen stealing from its retreat and creeping about in search of prey, which extends to all eggs it can meet with, and it not unfrequently destroys the bird that endeavours to defend them. If it enters the hen roost, the chickens are sure to fall victims; it does not often attack the cocks or old hens, nor does it devour what it kills

on the spot, but drags it off to eat at leisure. The weasel's appetite for animal food is insatiable and never forsakes it; though as soon as it has killed any animal, it sucks the blood, and does not attempt to touch the flesh till compelled by hunger.

The odour of the weasel is very strong, and is the most offensive in summer time, or when irritated or pursued.

Notwithstanding the report of its being so wild when kept in a cage, as to be in a continual state of agitation, and so shy of any person approaching to look at it, as to hide itself in the wool or hay given it for its bed, and of its constantly refusing to eat in the presence of any one, Buffon gives two instances of its being tamed. The one was of a lady, who tried the experiment upon a young weasel taken in her garden, which soon learned to recognise and lick the hand from which it received its food, and became as familiar and frolicsome as a dog or a squirrel. In the other case, a gentleman succeeded so completely in training a young weasel, that it followed him wherever he went, and would distinguish his voice, and spring over other persons to get to him.

The habits and manners of the weasel are as nearly as possible similar to those of the stoat already described.

WEN. A fleshy substance, that, in different instances, has been known to grow out almost on all parts of a horse's body. The cause from which they proceed is difficult to assign. They begin usually in the skin, where the vessels are extremely small; and these, enlarging gradually, in time grow to a considerable size.

Wens are seldom painful, owing to their small beginning and slow growth; being sometimes of several years standing before they arrive to any great size. They become at last like the natural flesh, and rarely are attended with any other bad consequence than the deformity, or weight, upon the parts where they are situated. Their substance is generally fleshy, and for the most part spongy; though some are spongy in part, with a mixture of schirrous hardness, of a scrophulous or cancerous disposition, especially when they arise among the glandular parts.

When a wen takes its origin from a tendon, or is attached to the fascia connected with the muscles, or when any part of a wen is involved with their fibres, the part generally appears, upon dissection, like so many threads laid close together; and this, according to some, is of the nature of a true schirrus. When a wen has a communication with the *membrana adiposa*, its substance is then chiefly an accumulation of a greasy matter resembling suet; and in some cases a consider-

able quantity of clear water has been found.

If it be deemed necessary to remove wens, the assistance of a skilful veterinarian is necessary.

WHIPPER-IN. The whipper-in is of much more importance than he is generally considered by those who do not study hunting, particularly to a pack of fox hounds; with harriers, the duty of the whipper-in is a minor consideration, and consists in little more than getting on the tailing or sluggish hounds. Beckford says, (and says truly) that no pack of fox hounds is complete without two whippers-in; the first is to be considered as the second huntsman, and should possess nearly the same good qualities. It is necessary besides that he should be attractive and obedient to the huntsman; and, as his horse will probably have most to do, the lighter he is the better; but if he is a good horseman it will sufficiently overbalance such an objection. He should not be conceited. "I had formerly one (says Beckford) who instead of stopping hounds as he ought, would try to kill a fox by himself. This fault is unpardonable: he should always maintain to the huntsman's halloo, and stop such hounds as divide from it—when stopped, he should get forward with them to the huntsman."

The first whipper-in must be contented to act an under part, except when circumstances require that he should act other-

wise. "I prefer (says the author from whom we have already quoted) an excellent whipper-in to an excellent huntsman. The opinion, I believe, is new; I must therefore endeavour to explain it.—My meaning is this, that I think I should have better sport and kill more foxes with a moderate huntsman and an excellent whipper-in, than with the best of huntsmen without such an assistant. My reasons are, that good hounds (and I would not keep bad ones) stand oftener in need of the one than the other; and genius, which, in a whipper-in, if attended by obedience, his first requisite, can do no harm; in a huntsman, is a dangerous, though desirable quality; and, if not accompanied with a large share of prudence, and I may say humility, will often spoil your sport and hurt your hounds. A gentleman told me he heard the famous William Dean, when his hounds were running hard in a line with Daventry, from whence they were at that time many miles distant, swear exceedingly at the whipper-in, saying, '*What business have you here?*' The man was amazed at the question. '*Why, don't you know (said he) and be d—d to you, that the great earth at Daventry is open?*' The man got forward, and reached the earth just time enough to see the fox go in. If therefore, whippers-in are at liberty to act as they shall think right, they are much less confined than the huntsman himself, who must follow his hounds; and consequently they have greater scope to exert their genius, if they have any."

The whipper-in should always be on the opposite side of the cover from the huntsman: if within hearing of his halloo, it is near enough; for that is the hunting signal he is to obey. The station of the second whipper-in may be near the huntsman, for which reason any boy that can halloo, smack a whip, and ride well may answer the purpose.

The first whipper-in should be able to hunt the hounds occasionally, and his being able to do so, will answer another good purpose—it will make the huntsman more attentive.

When the hounds leave the kennel, the first whipper-in should precede them; the second whipper-in should be some little distance behind them. "Such (says Beckford) should be the arrangement; if not, I fear, the hounds will not be suffered to empty themselves, let their wants be ever so great; for as soon as a boy is made a whipper-in, he fancies he is to whip the

hounds whenever he can get at them, whether they deserve it or not."

When a fox goes away, the first whipper-in should set off with the huntsman; but the second whipper-in should not leave the cover while a single hound remains in it; nothing can be worse than suffering hounds to remain behind; whilst keeping them well together is one of the surest means to render them steady.

The first whipper-in, if he possesses genius, will have frequent opportunities of exercising it: he may get forward to any great earth that by chance may be open; he may suck the wind to halloo or mob a fox when the scent fails; he may keep him off his foil; he may stop the tail hounds and get them forward; and has it frequently in his power to assist the hounds, without doing them any hurt, provided he has sense enough to distinguish where he is wanted most. Besides, the most essential part of fox hunting, the making and keeping the pack steady, depends entirely upon him; as a huntsman should seldom rate, and never flog, a hound. In fact, the first whipper-in may be justly considered as a second huntsman; and to be perfect, he should be as capable of hunting the hounds as the huntsman himself.

A whipper-in should always get to the head of the hounds before he attempts to stop them. The rating behind is to little purpose; and, if they are in cover, may prevent him from knowing which are the culprits. When hounds are running a fox, the first whipper-in should content himself with stopping such as are riotous, and should get them forward. They may be condemned upon the spot, but the punishment should be deferred till the next day, when they may be taken out for the purpose of committing the fault, and suffer the punishment accordingly.

A whipper-in, while breaking in young hounds, will sometimes rate them before they commit the fault: this prevents them for that time; but they will be just as ready to begin the next opportunity. He had much better let them quite alone, till he sees what they would be at; and the discipline may then be proportioned to the degree of offence. Whether a riotous young hound runs little or much is of small consequence, if he be not encouraged: it is the blood only that signifies, which in every kind of riot should carefully be prevented.

Whippers-in, when they rate a hound (we are still speaking of breaking-in

hounds,) if he does not pay attention, they should not keep rating on, but take up the delinquent immediately, and administer the whip very freely. A hound should always be well aware for what he is flogged; a hound should never be struck that does not deserve it; but those hounds that deserve punishment, should, generally speaking, receive it severely.

Whippers-in are apt to rate hounds and then endeavour to flog them. A dog, after being rated, will naturally avoid the whip. The whipper should strike first, and rate afterwards.

The second whipper-in should be very careful to bring home all the hounds. Beckford observes, "I lost an old hound for ten days, and sent all the country over to inquire after him; and, at last, when I thought no more about him, in drawing a large cover in the country where he had been lost, he joined the pack; he was exceedingly emaciated, and it was a long time before he was recovered."

The getting forward the tail hounds is a necessary part of fox hunting, in which a whipper-in is of the greatest service. He should get forward at times, when the huntsman is not with the hounds; but the

second whipper-in (who frequently is a young lad, ignorant of his business) on no account ought to encourage or rate a hound, but when he is quite certain it is right to do it; nor is he ever to get forward so long as a single hound remains behind.

As an interesting corollary to the present article, we shall introduce a sketch of the closing scene of Thomas Moody, for thirty years whipper-in to Mr. Forrester's hounds, in Shropshire. He was a striking instance of the ruling passion strong in death. By his own desire, he was carried to the grave by a number of earth-stoppers, and attended by many sporting friends; directly after the corpse, his favourite horse (named by himself *Old Soul*) followed, carrying his last fox's brush in the front of his bridle; his cap, whip, boots, spurs, and girdle being laid across the saddle; and after the burial service was read, there were, by his own desire, three rattling view halloos given over the grave.

This circumstance produced the following spirited composition from the pen of W. Pearce, Esq. it was set to music by Shield, and frequently sung with uncommon effect by Incledon:—

You all know Tom Moody, the whipper-in, well:  
The bell just done tolling was honest Tom's knell:  
A more able sportsman ne'er followed a hound  
Through a country, well known to him fifty miles round:  
No hound ever *challeng'd* so deep in the wood,  
But Tom well knew the sound, and could tell if 'twas *good*:—  
And all with attention would eagerly mark,  
When he cheer'd up the pack with—Hark! Rattler! hark! hark!  
High!—Wind him! and cross him!  
Now, Rattler, boy! Hark!

Six crafty earth-stoppers, in hunter's green drest,  
Supported poor Tom to "an *earth*" made for rest:  
His horse, which he styl'd his "*Old Soul*," next appear'd,  
On whose forehead the *brush* of his last fox was rear'd;  
Whip, cap, boots, and spurs, in a trophy were bound;  
And here and there followed an old straggling hound.  
Ah! no more at his halloo yon vales will they trace!  
Nor the Wrekin\* resound his first *scream* in the chase!  
With "High over! Now press him!  
Tally ho! Tally ho!"

Tom thus spoke to his friends, ere he gave up his breath—  
"Since I see you're resolv'd to be *in at the death*,  
One favour bestow—'tis the last I shall crave—  
Give a rattling *view halloo*, thrice, over my grave;  
And unless at that warning I lift up my head,  
My boys! you may fairly conclude I am dead!"

---

\* A large and well known mountain in Shropshire.

Honest Tom was obey'd, and the shout rent the sky,  
 For ev'ry voice join'd in th' enlivening cry—  
 "Tally ho! Hark forward!  
 Tally ho! Tally ho!"

WHOO-WHOOP. See the article HALLOO.

**WIGEON.** The wigeon is in length, twenty inches, and weight, twenty-four ounces; bill, narrow, of a blueish lead colour, an inch and a half long, tip, black; the top of the head is cream colour, over the bill, almost white; head and neck, light bay; the plumage of the back, and sides under the wings, undulated with black and white lines; wing coverts, brown, more or less mixed with, and in some birds almost, white; the greater quill feathers, dusky; the outermost webs of the middle feathers, of a fine green; the tips, black, the last striped with black and white; the two middle feathers of the tail are longer than the others, black and sharp pointed, the rest ash coloured; the belly, white; vent feathers, black; legs, dusky lead colour.

The head of the female is of a rusty brown, spotted with black; the back is of a deep brown, edged with a paler; the tips of the lesser quill feathers, white; the belly, white.

This species is common on most parts of the old continent; it is caught as low as Egypt, from the middle to the end of November, by nets in the marshes before the departure of the waters; it is also found at Aleppo, during the winter, in plenty; observed, likewise, in the Caspian sea and its neighbourhood; and in most parts of Europe, as far as Sweden. It abounds in England during the winter months, and is caught in the decoys; it is said not to breed in France, nor is it certain that they breed in this country. Both sexes are alike until the following spring after hatching, (this obtains in the pintail, the gadwall, and the shoveller, who are all grey and have no beautiful feathers when young,) when the males about March gain their full plumage, but lose it again at the end of July, and with it, in some measure, their voice, which they regain, and always use during their flight, in the winter season, and which is thought to be like the sound of a fife. Their flesh is much esteemed, and they are easily domesticated in places where there is much water, and are greatly admired for their beauty, sprightly look, and active frolicksome motions.

**WILD FOWL.** Under this head may be classed all those birds which frequent the rivers, marshes, fenny places, and the sea shore, and which have been noticed under distinct heads.

Some of them do not exactly come under the description of game, at least in the eye of the law; but they are all objects of interest to the sportsman, particularly to those sportsmen who reside near the sea, or in the vicinity of large rivers, fens, or marshes.

The progressions of nature from one class of beings to another, are always by slow and almost imperceptible degrees. She has

peopled the woods and the fields with a variety of the most beautiful birds; and, to leave no part of her extensive territories untenanted, she has stocked the waters with its feathered inhabitants also: she has taken the same care in providing for the wants of her animals in this element, as she has done with respect to those of the other; she has used as much precaution to render water-fowl fit for swimming, as she did in forming land-fowl for flight; she has defended their feathers with a natural oil, and united their toes by a webbed membrane; by which contrivances they have at once se-

curity and motion. But between the classes of land-birds that shun the water, and water-fowl that are made for swimming and living on it, she has formed a very numerous tribe of birds, that seem to partake of a middle nature ; that, with divided toes, seemingly fitted to live on land are at the same time furnished with appetites that chiefly attach them to the waters. These can properly be called neither land-birds nor water-fowl, as they chiefly derive their sustenance from watery places, and yet are unqualified to seek it in those depths where it is often found in the greatest plenty.

This class of birds, of the crane kind, are to be distinguished from others rather by their appetites than their conformation. Yet even in this respect they seem to be sufficiently discriminated by nature : as they are to live among the waters, yet are incapable of swimming in them, most of them have long legs, fitted for wading in shallow waters, or long bills proper for groping in them.

Every bird of this kind, habituated to marshy places, may be known, if not by the length of its legs, at least by the scaly surface of them. Those who have observed the legs of a snipe or a woodcock, will easily perceive my meaning ; and how different the surface of the skin that covers them is from that of the pigeon or the partridge. Most birds of this kind also, are bare of feathers half way up their thighs ; at least, in all of them, above the knee.—Their long habits of wading in the waters, and having their legs continually in moisture, prevents the growth of feathers on those parts ; so that there is a surprising difference between the leg of a crane, naked of feathers almost up to the body, and the falcon, booted almost to the very toes.

The bill is also very distinguishable in most of this class. It is, in general, longer than that of other birds, and in some finely fluted on every side ; while at the point it is possessed of extreme sensibility, and furnished with nerves, for the better feeling their food at the bottom of marshes, where it cannot be seen. Some birds of this class are thus fitted with every convenience : they have long legs, for wading ; long necks, for stooping ; long bills, for searching ; and nervous points, for feeling. Others are not so amply provided for ; as some have long bills, but legs of no great length ; and others have long necks, but very short legs. It is a rule which universally holds, that where

the bird's legs are long, the neck is also long in proportion. It would indeed be an incurable defect in the bird's conformation, to be lifted upon stilts above its food, without being furnished with an instrument to reach it.

If we consider the natural power of this class, in a comparative view, they will seem rather inferior to those of every other tribe. Their nests are more simple than those of the sparrow ; and their methods of obtaining food less ingenious than those of the falcon ; the pie exceeds them in cunning ; and though they have all the voraciousness of the poultry tribe, they want their fecundity. None of this kind, therefore, have been taken into man's society, or under his protection ; they are neither caged like the nightingale, nor kept tame like the turkey, but lead a life of precarious liberty in fens and marshes, at the edges of lakes and along the seashore. They all live upon fish or insects, one or two only excepted.

All this class, therefore, that are fed upon insects, their food being easily digestible, are good to be eaten ; while those which live entirely upon fish, abounding in oil, acquire in their flesh the rancidity of their diet, and are, in general, unfit for our tables. To savages, indeed, and sailors on a long voyage, every thing that has life would appear good to be eaten ; and we often find them recommending those animals as dainties, which they themselves would spurn at after a course of good living. Nothing is more common in their journals than such accounts as these—"this day we shot a fox—pretty good eating ; this day we shot a heron—pretty good eating ;" and, "this day we killed a turtle"—which they rank with the heron and the fox, as "pretty good eating." Their accounts, therefore, of the flesh of these birds, are not to be depended upon ; and when they cry up the heron or the stork of other countries as luxurious food, we must always attend to the state of their appetites who give the character.

**WILD FOWL SHOOTING.** This amusement is never likely to be held in general estimation ; yet in the severity of a hard winter, it will afford diversion of a secondary order, or enliven a dull season, when superior field sports are not to be obtained ; when, in fact, from the state of the weather, the chase of the hare and the fox is out of the question ; and when, indeed, the pursuit of the partridge, &c. may be considered, at least, as very un-

advisable, and frequently abortive—in-  
deed, in a hard frost, pointers cannot  
range, the state of the ground being such  
as very soon to cut their feet to pieces.  
In such cases, cock shooting may be fol-  
lowed as well as snipe shooting; and to  
these may be added wild-fowl shooting in  
general.

Wild-fowl shooting, we are perfectly  
aware, is pursued throughout the winter;  
but unless the frost be sufficiently severe  
so as to enable the sportsman to walk  
upon the ice over the marshes, it appears,  
at least to us, but a shivering sort of busi-  
ness. When a well frequented marsh be-  
comes completely frozen up, the birds  
which haunt such places, from want of  
food, become less shy, and the calls of  
hunger keep them constantly on the move  
throughout the day, which is not the case  
at other times, as they seldom fly, in  
open weather, except early in the morn-  
ing and as the dusk approaches in the  
evening.

In severe frosts, therefore, the sports-  
man is not under the necessity of hiding  
himself behind some reeds or other screen  
and waiting till the birds pass, but can  
keep his blood in tolerable circulation by  
walking about, and if the frost has been  
of any continuance, he will be very likely  
to obtain good sport; for, as all wild-fowl  
are very shy in general, it is only on oc-  
casions like these, when they are suffer-  
ing from hunger, that they will permit  
the approach of the sportsman.

In severe frosts, the sportsman will do  
well to walk by the side of running  
streams and brooks, in the vicinity of the  
marsh, and those in particular which are  
sheltered by trees, hedges, or other cover;  
as wild ducks, and birds of the duck  
kind, will be very frequently found in  
them.

And here it may not be amiss to say a  
few words upon the erroneous notion  
which has so long prevailed respecting  
the use of enormously long guns in wild-  
fowl shooting, where the object is fre-  
quently at a considerable distance, and  
on account of the peculiar hardness of its  
feathers, is not so easily brought down as  
a partridge, pheasant, &c. The author  
of the "Shooter's Companion," to which  
we have repeatedly referred, was the first  
to place this subject before the eyes of  
sportsmen in a clear and forcible light;  
and, therefore, to our article on the FOWL-  
ING PIECE, which completely embodies the  
the said author's ideas, we refer our readers  
for further information on the subject.

Candour, however, and common justice  
compels us to state, that the erroneous  
notion respecting the length of gun bar-  
rels is yet not completely exploded; on  
the contrary, it is still maintained by those  
who ought at least to be better acquainted  
with the subject, since they profess to  
give advice to others through the me-  
dium of the press; but it is happy for  
mankind, that this almost divine engine  
(the press) can correct itself, as it were;  
and thus, though it is occasionally per-  
verted into an instrument for the propa-  
gation of crude ideas, consummate ig-  
norance, and besotted stupidity; yet the  
inconsiderate and flimsy impression which  
the thoughtless thus receive, vanishes,  
generally speaking, before the touch-stone  
of truth, like a pestiferous exhalation be-  
fore the bright beams of a splendid sun.

Colonel Hawker, in his "Instructions  
to Young Sportsmen," observes, "a short  
time ago, I had made up my mind, that  
a barrel, of whatever size it might be,  
would kill the farthest, if made forty-eight  
times the diameter of the intended calibre,  
and entered in the MSS. for this edition  
some observations to that effect. But  
had they gone to the press I should have  
been open to the criticism of every good  
experimentalist: for I have since dis-  
covered, that *the larger the gun, the longer  
it must be in proportion* (quite wonderful!)  
because the further the shot has to travel,  
the greater must be the resistance of the  
atmosphere."—(What a discovery!)

The Colonel, to prove his position, talks  
about guns, the barrels of which, weigh  
from 59 to 69lbs; weights, we presume,  
which few sportsmen would feel disposed  
to carry! and remarks, "fire a fourteen  
gauge sporting gun, two feet eight inches,  
or forty-four diameters, at Mr. Manton's  
iron door, against one of three feet, and  
there will probably be no difference." Hence  
it would appear, after all, that Colonel  
Hawker could not get rid of some lurking  
doubts in his mind respecting his  
hypothesis, for he here makes an admis-  
sion, which overturns "at one fell swoop"  
what he has wriggled and laboured, so  
hard and so awkwardly to establish. Co-  
lonel Hawker is evidently much attached  
to wild-fowl and shore shooting; and we  
have not the least objection to believe  
that he is very expert at the business;  
but since he has chosen to give his ex-  
cogitations to the world through the me-  
dium of the press, his work has thus be-  
come a fair subject of animadversion;  
and we must observe, that most of his

notions are stale or a century behind the present state of things; that his ideas are very clumsily expressed; and that his "Instructions to Young Sportsmen," we consider as worse than nothing.

We have already remarked that we considered wild-fowl shooting as a secondary sort of amusement, but preferable in a hard frost to any other time; but to those who are partial to this diversion at all seasons, we would recommend to go well prepared both internally and externally, and never to be without a flask of brandy; water-proof boots are also advisable; and in order to render boots water-proof, the following receipts have been frequently and, we believe, successfully, used:—

One pint of linseed oil, half a pound of mutton suet, eight ounces of bees' wax, and one pennyworth of rosin: the whole to be boiled together, and warmed before using.

*Another.*—If the boots are new, take half a pound of bees' wax, a quarter of a pound of rosin, and one pound of tallow: to be boiled well together, and warmed before using.

The boots should, of course, be well cleaned from the dirt, and perfectly dry, before the application of either of the above receipts.

The soles of the boots might have a layer of cork, or waxed canvas introduced betwixt them.

Indian rubber dissolved in spirit of wine, spirit of asphaltum, or spirit of turpentine, and rubbed on the boots, renders them completely impervious to water.

Fishermen are said to use the following preparation for their boots:—bees' wax, Burgundy pitch, and clean turpentine, of each, two ounces; clear rendered tallow, four ounces:—all melted together and applied over a weak flame until the leather fills. The liquid should be applied by degrees, and one portion dried in before another is spread over.

As fen birds are by nature extremely shy, and very suspicious of the approach of a human being, so the principal consideration is how to get within gun shot. Various devices have been used for this purpose, and, amongst the rest, the stalking horse (which has been already noticed under its proper head); but the method now generally resorted to for the purpose, is to occupy some station, by which it is expected the birds will pass, when flying to feed. We have already observed that these birds fly and feed at the dawn of

day, and also towards the dusk of evening; these are the times, therefore, which are chosen by the sportsman for effecting his purpose. As the haunts of the fowl are generally known, the stations are taken accordingly, and for the purpose of reaching the most eligible spots, a small boat or punt is frequently necessary; and those who have been accustomed to the business sometimes prove very successful. Such people are able to shoot either by the eye or the ear; for, as the fog or the darkness of the night frequently prevents them from seeing their object, they listen to the noise made by the bird's wings, and direct their aim accordingly—some of these people shoot with astonishing accuracy under such circumstances.

On the extensive marsh called Martin Mere, in Lancashire, many of the cottagers who reside on its borders, make a living during the winter by shooting and catching ducks and fen birds. For this purpose they go out regularly night and morning; and as they are well acquainted with the manner and haunts of the fowl, and the direction of their flights (which will be regulated by the wind) they seldom return home utterly unsuccessful. Those gentlemen who wish to partake of the amusement of fen shooting, cannot do better than put themselves under the guidance of those who reside, as it were, on the marsh.

Those, however, who make a living by catching fen birds do not confine their operations to the fowling-piece; on the contrary, they capture ducks and also other birds (and snipes in particular) by means of snares, placed in and by the side of the water. These snares require attention; for kites and other rapacious birds which are constantly to be seen about marshes and fens, are always on the look out, and when a bird happens to be caught, if it be not immediately taken out of the snare, it is almost sure to be pulled to pieces by them, and the snare, perhaps, destroyed into the bargain.

Fen shooting is, of course, most followed in Lincolnshire and Cambridge-shire, where the most extensive and the best stocked fens are to be met with.

Shore shooting offers, perhaps, superior sport for those who are partial to this species of diversion; of which, Mr. Gilpin has given an interesting description:—"The coast between Hampshire and the Isle of Wight (says he) is peculiar, consisting, at ebb tide, of vast muddy flats, covered with green sea weed: it

affords the fowler an opportunity of practising arts perhaps not elsewhere resorted to. Fowling and fishing are, indeed, on this coast, commonly the employments of the same person. He who in summer, with his line or net, plies the shores, when they are overflown by the tide; in winter, with his gun, as evening draws on, runs up in his boat among the little creeks which the tide leaves in the mudlands, and lies in patient expectation of his prey. Sea fowl usually feed by night, when in all their multitudes they come down to graze on the savannahs of the shore. As the sonorous cloud advances (for their noise in the air resembles a pack of hounds in full cry) the attentive fowler listens which way they bend their course; perhaps he has the mortification to hear them alight at too great a distance for his gun to reach them; and if he cannot edge his boat round some winding creek, which is not always in his power to do, he despairs of success that night; perhaps, however, he is more fortunate, and has the satisfaction to hear the airy noise approach nearer, till at length the host settles in some plain upon the edge of which his boat is moored: he now, as silently as possible, primes both pieces anew (for he is generally double armed) and listens with all his attention: it is so dark that he can take no aim, for if he could discern the birds they would see him; and being extremely timorous, would seek some other pasture. Though they march with noise, they feed in silence; some indistinct noises, however, if the night be still, issue from so vast a concourse; he directs his piece, therefore, towards the sound, fires at a venture, and instantly catching up his other gun, discharges it where he supposes the flock to rise on the wing. His gains for the night are now decided, and he has only to gather his harvest; he immediately puts on his mud pattens (flat square pieces of board which the fowler ties to his feet, that he may not sink in the ooze) ignorant yet of his success, and goes groping about in the dark in quest of his booty, picking up sometimes many, sometimes not one. So hardly does the poor fowler earn a few shillings, exposed in an open boat during a solitary winter night, to the weather as it comes, rain, hail, or snow, on a bleak coast, a league probably from the beach, and often liable, without great care to be fixed in the mud, where he would become an inevitable prey to the returning tide. I have heard

one of these poor fellows say, he never takes a dog with him in these expeditions, because no dog could bear the cold which he is obliged to suffer; and, after all, others frequently enjoy more from his labours than himself; for the tide often throws, next day, on different parts of the shore, many of the birds which he had killed, but could not find in the night.

“ This hazardous occupation once led a fowler into singular distress; it happened too in the day time, which shews still more forcibly the risk of such nocturnal expeditions. Mounted on his mud pattens, he was traversing one of those oozy plains in search of ducks, and, being intent only on his game, suddenly found the water, which had been accelerated by some peculiar circumstance affecting the tide, had made an alarming progress around him, and he found himself completely encircled: in this desperate situation, an idea struck him as the only hope of safety: he retired to that part which seemed the highest, from its being yet uncovered by water, and striking the barrel of his long gun deep into the ooze, he resolved to hold fast by it, as well for a support, as a security against the waves, and to wait the ebbing of the tide: he had reason to believe that a common tide would not have flowed above his middle; but in the midst of his reasoning upon this subject, the water had now reached him; it rippled over his feet; it gained his knees, his waist; button after button was swallowed up, until at length it advanced over his shoulders: with a palpitating heart, he gave himself up for lost: still, however, he held fast by his anchor: his eye was eagerly in search of some boat, which might accidentally be passing, but none appeared. A head upon the surface of the water, and that sometimes covered by a wave, was no object to be descried from the land, at the distance of half a league; nor could he exert any sounds of distress that could be heard so far: while, as the exigence would allow, he was making up his mind to the terrors of certain destruction, his attention was called to a new object; he thought he saw the uppermost button of his coat begin to appear. No mariner floating on a wreck could behold approaching succour with greater transport than he felt at this transient view of his button; but the fluctuation of the water was such, and the turn of the tide so slow, that it was yet some time before he durst venture to assure himself that the button

was fairly above the level of the flood ; at length a second button appearing at intervals, his sensations may rather be conceived than described : and his joy gave him spirits and resolution to support his situation four or five hours longer until the waters had fully retired."

The danger of following wild-fowl in the small boats generally used by these people is much increased when there is ice in the river, by which they sometimes get encircled, and then can only float with the current, and they are often kept two or three tides before they can extricate themselves ; and their punt is ill calculated to sustain pressure against its sides, which are not twenty inches high from the surface of the water ; in such a vehicle the fowler drops down by night with the tide, or uses his paddles after the fowl ; he knows their haunts and takes every advantage of the wind, tide, moon, &c. his gun, which carries as much as a little cannon, is laid with the muzzle over the stem of the boat, in a hitch, which regulates the line of aim : the fowler lies at the bottom of the boat or punt on his belly, and gets as near the fowl that are upon the water as possible ; when within the range of his gun, he rattles with his feet against the bottom of the boat, and just at the moment when the fowl spring, he pulls the trigger, and cuts a lane through their ranks ; he instantly follows the direction of his shot, and gathers up those that are killed, or just expiring, for it very seldom answers to row after birds only wounded ; he then loads again, and drifts farther down the river, in hopes of obtaining more shots. By this mode a man has been known to bring home a hundred wild-fowl of various kinds in one night's excursion. The numbers that are seen in their day flights, and the noises of the various kinds at night, are almost incredible.

The best time for the species of shooting now under consideration is the first or second day's thaw after a sharp frost, and when deep snow has long covered the ground ; the fowl are then flying in every direction to dabble in the fresh, which at such periods seems very inviting to them. Another favourable opportunity is at the commencement of a frost, with the wind strong at east, and a sleet or snow falling ; the birds are more easy of approach in such weather and always fly lower than when the atmosphere is clear.

The guns used for shooting wild-fowl in punts generally carry about two pounds

of shot, and are fixed in the boat in the manner already described. It need hardly be observed that very large shot is used.

Hearne says, that wild swans, notwithstanding their bulk, are so extremely swift on the wing, when in full feather, as to make them more difficult to shoot than almost any others, it being frequently necessary to take sight ten or twelve inches before their bills. This, however, is only when they are flying before the wind in a brisk gale, at which time they seldom fly at a less rate than one hundred miles an hour ! but when flying across the wind or against it, they are not able to make any great progress. Of the Brent geese, he says, that, when migrating to the south, they generally avail themselves of a strong north or north-westerly wind, which makes their flight so swift, that when he has killed four or five at a shot, not one of them fell less than from twenty to fifty yards from the perpendicular spot where they were killed.

A gentleman in the county of Durham, observed a flock of wild geese one morning in April, going northward in the line of two objects, with the distance of which he was well acquainted—it was four miles : he noticed by his watch, as nearly as possible, the time the geese were in flying it, from which he calculated that if they continued to fly at the same rate for twelve hours, they would be at the Orkney Islands by sun set, which would be passing through the air at the rate of five and twenty miles an hour.

On this subject, Major Cartwright, in his Journal of a Residence off the coast of Labrador, observes, " I measured the flight of the eider duck by the following method : viz. on arriving off Duck Island, six miles distant from Henley Tickle, I caused the people to lie on their oars ; and when I saw the flash of the guns, which were fired at a flock of ducks as they passed through the latter, I observed by my watch how long they were flying abreast of us. The result of very many observations ascertained the rate of their flight to be *ninety miles an hour* !

The great art or secret of wild-fowl shooting is the mode of approach ; and of late years, this, in some parts, has been improved. The winter of 1821—1822, was very severe ; and vast flocks of wild-fowl visited the river Dee in Cheshire. Great numbers of them were seen on the water in the day time ; but they were

not easy to approach. Heaps of conglomerated ice and snow floated daily down the river; and this circumstance being noticed by a wild-fowl shooter, he contrived so to disguise his boat, as very well to counterfeit the appearance of these floating masses: he thus contrived to drift amongst his game, and his success was almost incredible.

In India, wild-fowl are caught by means somewhat similar. On the river Ganges, wild ducks are frequently seen in great numbers; and as gourds are constantly floating down the river, the fowlers of these parts took the hint; thus, a man, placing his head in a hollow gourd, in which, small holes were formed to enable him to discern his object, walked into the water, taking care to let nothing be seen but the gourd. The birds, no way suspicious of a sight to which they were so perfectly familiar, suffered the fowler to introduce himself amongst them; when seizing them by the legs, he drew them under water one after another, and fastening them to his girdle, retired when he had captured a sufficient number; or, at least, when he had filled his girdle.

As far as relates to what we consider as the real amusement or diversion of wild-fowl shooting, there is perhaps no part of Great Britain where it can be enjoyed in greater perfection than in the Highlands of Scotland. Great numbers of wild ducks breed on the lakes in these parts that are fringed with cover, or where there happens to be small spots or islands in the midst of them; and in winter these places are visited by vast quantities of wild-fowl, particularly those lakes which have a communication with the sea, where flocks of these birds are very frequently to be seen. Also, on the rocky shores of this part of the world, immense numbers of wild-fowl may be met with at almost any period of the year; where likewise rock pigeons are found in great abundance. On the coast of Caithness, persons go out sometimes upon what may be called general shooting parties; and on these occasions, it would seem that the mere amusement of killing was the principal object, as gulls, cormorants, petrels, or, indeed, any bird which presents itself within reach seems to be considered fair game.

Something of this sort also takes place about the Isle of Man, where the rocks offer a convenient situation for sea-fowl to breed, and to which they resort in almost incredible numbers. Towards the

latter end of the summer, when the young gulls and other young sea birds are able to fly, parties go out, and shoot immense numbers of these birds, which, however, furnish no very great dainty for the table.

The writer is acquainted with a gentleman, who is passionately fond of shooting, but from the circumstance of being lame, is not able to pursue this amusement on land, at least with much satisfaction. He, however, amuses himself with shooting on the water; and is enabled to follow his darling passion with comfort and convenience. He has several boats; and, amongst the rest, one which is decked, and fitted up with cooking apparatus, berths for sleeping, &c.—In this, he coasts along the shore, and shoots such birds as happen to present themselves. From him we were informed that even the sea-gull is tolerable eating when *skinned and properly dressed*; and he even described to us the process of rendering it palatable and *even delicious*; but as few of our readers, we feel persuaded, will feel much interest in the description we shall not tire them with the details. When night approaches, if accommodations happen to be at hand on shore, the boat or vessel is secured for the night; otherwise he and his servants sleep on board. And we are really inclined to think that this is one of the most eligible, and one of the pleasantest, methods of wild-fowl shooting; which, after all, we cannot help considering as nothing more than a mere apology for superior diversion.

Even Colonel Hawker himself, whose life and soul seem to be made up for wild fowl shooting, cannot avoid making an appalling exordium to his own observations on the subject:—"This amusement (says he) is generally condemned as being only an employment for fishermen, because it sometimes interferes with ease and comfort, and *bucks shiver at the idea of being posted, for hours, by the side of a river, or anchored half a night among the chilling winds in a creek!*" It must, we think, be generally admitted that such circumstances form by no means pleasing preludes to wild fowl shooting.

There is a variety of circumstances connected with wild fowl shooting at least on the sea shore, which harmonize but very little with our ideas of diversion: we will again have recourse to the worthy Colonel for information on the subject:—"The Hampshire punts are now built rounder at the stern, and the recoil of the

gun is received entirely by a knee fixed only to the bottom plank (instead of a cross piece) which is far safer, and decidedly less liable to tear away the sides of the punt. The bottom is now made of one elm plank, an inch and a quarter thick, to which the knee is fixed by bolts and screws; and, consequently, as there is no recoil on the sides of the punt, every part, but this plank, is made as light as possible.

As a proof of my former arguments against the safety of the Hampshire punts, I need only observe, that, since my last edition, three men, (Vincent, Jones, and Tanner,) were drowned; and another (Harnet) was killed by his gun. These regular western channel gunners are now, therefore, become very shy of shooting afloat, for which (by having punts that are so *crank*, and draw so much water, and guns proportionably so short in the barrel) they have always been the worst equipped of any '*big gunners*,' (as they call themselves) on the British coast.

They have, therefore, of late years adopted an entirely new mode of getting at the birds, for which that vast track of ooze near Lymington is better calculated than any other mud in the world.

They start off generally in the afternoon (provided the tide serves, so as to be low enough at the proper time) keeping as close as possible to the shore, and going before the wind till they arrive at the leeward end of their beat; the whole track of which, for one night's work, may be about five or six miles. They then go ashore, and either get into a pot-house, if they have a six-pence to spend, or lounge about the shore till day light disappears, and the birds begin to fly, having first put all '*in order*;' that is, to draw out their mould shot, which they generally have in, for the chance of a goose, '*going down along*,' put in smaller shot, and regulate their gun, so that it will bear about eighty yards, when the punt is on the dry mud. No sooner are the wigeon pitched, than off they set in tarpaulin dresses, and looking more like chimney sweepers than gunners, *crawling on their knees, and shoving the punt before them on the mud!* No matter whether light or dark, few

birds or many, *bang* goes the gun; and no sooner have they picked up what few birds are readily to be found, or missed the fowl, which they very frequently do, as the punt, by even a few perriwinkles, might be thrown off the line of aim, they proceed again; thus travelling all night (by '*launching*' over the mud, and rowing across the creeks) in a direct line, similar to the march of an *army of coots*."

Those who are anxious for further information on the subject of "*shoving*" punts or boats over the mud, and the like, we refer to the *very luminous* work of Colonel Hawker, where they will find considerable *verbiage*, if not much acuteness of remark, or elegance of diction.

We will be candid and do the Colonel justice: for amongst the wretched and contemptible mass of worse than nonsense, which he has published under a very specious title, there is one paragraph which bears the stamp of sense and reflection:—we will quote it:—"In getting at all wild birds, approach them circuitously, instead of going directly up to them; and avoid looking full at them until you have got within shot, or till they shall, if flying, have come sufficiently close for you to fire. If you see a wild bird, when unprepared for him, either continue your course without looking at him, or instantly retreat, and he may then probably sit quiet till you can advance with caution on him a second time. If a valuable bird lies wounded, always go up to him prepared to shoot, lest he should rise again and make his escape."

For the purpose of wild fowl shooting, the French form huts near the haunts of the birds, disguising them as much as possible, having loop holes, as it were, through which to fire.

There are several of the larger kind of birds, which perhaps may be classed among wild fowl, such as the heron, the bittern, &c. These are sometimes to be seen on the sea shore, but generally in the fens and marshes; where they sometimes present a shot to the sportsman; though they are in general very shy of approach; and even when killed, they do not furnish a dainty for the table.

**WILD TURKEY.** In some parts of America, the turkey is found in a state of unlimited freedom, associating in flocks, sometimes to the amount of five hundred, and affording good diversion to the transatlantic sportsman.

In Canada, pursuing these birds forms one of the principal diver-

sions of the natives of that country. When they have discovered the retreat of the turkey, which in general is near fields of nettles, of the seeds of which they are particularly fond) or where there is plenty of any kind of grain, they send a well trained dog into the midst of the flock. The birds no sooner perceive their enemy than they run off at full speed; the dog pursues, and the birds, in order to escape from him, are compelled eventually to take shelter in a tree; where they remain till the sportsmen come up, when they suffer themselves to be knocked down one after another, which is done, we are told, by means of long poles.

It appears that in the wilds of America, the turkey grows to a much larger size than with us. Josselyn says that he has eaten part of a turkey cock, which, after it was plucked and the entrails were taken out, weighed thirty pounds.

Turkeys frequent the great swamps of America to roost; but leave these situations at sun rise to repair to the dry woods in search of acorns and berries. They perch on high trees, and gain the height they wish by rising from bough to bough: they generally mount to the summits of even the loftiest. They are very swift runners, but very awkwardly; and about the month of March they become so fat that they cannot fly beyond three hundred yards, and are then easily run down by a horseman, when they happen to be found in situations calculated for the purpose, or for such a chase.

Michaux, in his travels to the Allegany Mountains, says, "The wild turkeys, which begin to be very scarce in the southern states, are plentiful in those to the westward. In the most uninhabitable parts, they are so tame as to be easily killed with a pistol shot. In the east, on the contrary, and particularly in the neighbourhood of the sea ports, they cannot be approached without great difficulty: they are not alarmed by a noise; but they have a very quick sight, and so soon as they discern the hunter, flee away with such rapidity, that it takes a dog several minutes to come up with them: and when they perceive themselves on the point of being caught, they escape by taking flight. The wild turkeys generally perch on the tops of the highest trees, where, notwithstanding their bulk, it is not easy to see them; when they have not been frightened, they return to the same trees for several weeks in succession.

To the east of the Mississippi, in a space of more than eight hundred leagues, this is the only sort of wild turkey which is met with. They are larger than those reared in the poultry yards. In autumn and in winter, they feed chiefly on chesnuts and acorns; and some of them, killed at these seasons, weigh thirty-five or forty pounds."

Turkeys were not known till the year 1524. This bird is so well known as not to require description; their colours vary, but in all of them, the tuft of black hair upon the breast of the male is prevalent.

WIND - GALL. A puffy kind of swelling or tumour which yields to the pressure of the finger, but upon removing the pressure recovers itself and pushes out as before. They have been thus named from a false notion of their containing nothing but air, or wind. These tumours are often seated on both sides of

the back-sinew of a horse, above the fetlock on the fore-legs, but most frequently on the hind-legs. They are quite loose and detached from the parts on which they grow, and exhibit the same signs wherever they are met with, whether in the hocks or about the knees; for these swellings are not confined to the lower limbs only, but appear in any of those parts of a horse's body where the cellular membrane can be easily separated; and they exist, for the most part, without occasioning pain.

Wind-galls are usually caused by riding on very hard roads, or on dry hilly grounds. Sometimes travelling horses, when they are worked too young, before the limbs are grown firm and vigorous, will have them. Gibson says they sometimes proceed from constitutional weakness, especially in bulky horses, that are somewhat under limbed and fleshy about the fetlock joint. These, he says, he has known to have wind-galls without any strain, hard riding, or other ill usage.

When these tumours appear upon the hind legs they never cause lameness, though such horses are often stiff behind after riding. When on the fore-legs, they always make a horse go lame at first; but afterwards that tenderness goes off in a great measure, and they seldom go lame, but stiff, and inclinable to stumble. They generally recover, however, with a day's rest. Those flatulent swellings indeed that come in the ligaments of the hocks are always troublesome, disfigure the animal, and, unless speedily assisted, will cause incurable lameness. At first they are but small, but in time they grow to the size of a pullet's egg perhaps, and push out on each side of the hollow of the hock. Swellings of the same kind also appear above the knee, where they often precede a diseased joint. Very small similar swellings under the fore-part of the knee, in the interstices of both sides of the joint, are also dangerous; but these seldom happen, and are usually caused by some violent strain, especially when a horse falls down upon a descent with his whole weight upon his knees. The other flatulent swellings which horses are subject to seldom cause lameness, but are, for the most part, easily cured. We mean those that arise in the interstices of the large muscles of the hips and thighs, which are distended like little bladders filled with air. These come by strains and over exertion; for draught horses are the most subject to them of all others. Wind-galls

that proceed from mere weakness are seldom curable, unless the constitution can be improved; but we often see horses that were subject to wind-galls when young, get the better of them as they grow to maturity.

Wind-galls that proceed from hard riding, or the other causes above mentioned, are more easily prevented than cured; for though few horses go lame with these tumours, yet they always disfigure the part where they are situated; and therefore young horses of value ought not to travel much, especially with heavy riders, before they come to their full strength. If they swell about the pasterns, and the swelling does not ascend towards the knee, but with an apparent fullness on each side the back sinew, it is to be suspected wind-galls are taking place. With a view to prevent their progress, Gibson advises us to bathe them well with vinegar or verjuice, or other powerful astringents.

But when wind-galls are grown pretty large, they feel like kernels or indurated glands. If these be in the hind-legs, it is scarce worth while to meddle with them; as we see many good hacks and road horses travel long journeys with these defects without going lame; but when they are situated on the fore-legs, they are apt to make a horse trip and stumble, or at least appear very stiff after riding. In this case the cure may be attempted by mild blisters. Some merely pierce them with a lancet, but that often inflames and renders them more obstinate, whilst blisters, often repeated, dissipate them effectually. Gibson says, blistering always has this effect in those wind-galls that arise above the fetlock, and sometimes he has known blistering alone to succeed in these tumours when situated on the hocks; but this has been repeated, at times, for the space of a year or a year and a half, working the horse as usual in all the intervals. These accidents happen chiefly to coach horses and others that draw heavy loads, and the best way to manage their blisters is this: a little blistering ointment should be laid on every other day for a week, which brings on a plentiful discharge, and when this is dried up, which generally happens in a few days, the horse may go to his usual work for three weeks or a month, after which the blistering may be repeated, if it be a convenient time for the owner, or at any other season when the horse can have a little rest. Horses have been blistered in this

manner six or eight times within the year, by which means they daily got some ground. The swellings gradually were reduced, the parts strengthened, and no manner of blemish has been left, nor any loss of hair, and the lameness has been entirely removed. Firing is indeed a more expeditious remedy, being but a single operation, which is seldom or never repeated; yet firing not only leaves blemishes, but Gibson asserts it is, for the most part, an imperfect cure, as there always remains a stiffness and fulness about the joint; and the only good obtained by it is, that it stops the progress of the malady, and renders a horse much

more useful than he was before the operation.

For those flatulent swellings that sometimes rise near the joint of a horse's knee, if astringent applications have not force enough to remove them, the best way is to blister without delay, for when these are seated near the knee they prove dangerous, unless speedily removed. For this reason, firing is also proper after blistering; but this should be done with a small iron, and the lines or rases made as near to one another as possible, afterwards covering the whole knee with a mercurial application.

**WITHERS.** The part of a horse so at the termination of the mane, from called, is the superior point of the shoul- whence the back begins.  
ders, situate above the blades, precisely

**WOLF.** It is very well known that wolves were formerly very common in this country ; but as the population increased, and as the cultivation of the soil proceeded accordingly, these animals retired before the arts of civilization, and have long since been extinct. The extermination of the wolf in England was first attempted by Edgar ; and this monarch remitted the punishment of certain crimes on producing a specified number of wolves' heads ; and commuted the tax of gold and silver imposed upon the Welsh for an annual tribute of three hundred wolves' heads. However, some centuries after this period, wolves had increased so much as to become an object of attention to Edward I. who, in the ninth year of his reign, issued his royal mandate to Peter Corbet, to superintend and effect their destruction in the counties of Gloucester, Worcester, Hereford, Salop, and Stafford. In other counties great rewards were also given for destroying them. Camden informs us that certain persons held their lands on condition of hunting and killing the wolves that infested the country ; whence they were called the *wolrehunt*. In the reign of Athelstan, wolves were so numerous on the wilds (now called *wolds*) of Yorkshire, that a retreat was built at Flixton to defend passengers from their attacks. As the ravages of these animals were greatest during the winter, particularly in January, when the cold was severest, our Saxon ancestors distinguished that month by the title of *wolf-month*. They also called an outlaw, *wolfshed*, as being out of the protection of the law, and as liable to be killed as that destructive beast.

The Scottish monarch, James I. orders his "Schireffs and Barons to hunt the wolf four or thrie times in the yeare, betwixt St. Mark's Day and Lambes, (from April 25 to August 1) quich is the time of their quhelpes."—The succeeding monarch, James II. by act of parliament, about the year 1451, directs the sheriffs "to hunt and slay the wolfe and her quhelpes, three times in the year ; and all indwellers of the shire shall rise with them, under pain of one *wedder*." The last refuge of these animals in Great Britain was in the High-

lands of Scotland ; where the last wolf was killed by Sir Ewen Cameron of Lochiel, in the year 1680, in the Lochaber mountains ; where, from the rugged and frightful nature of the country, it might be naturally enough supposed, that these fierce creatures would make their last stand.

In Ireland, wolves continued after this period : the last presentment for killing wolves was made in the county of Cork about the year 1710 ; though a wolf is mentioned as having been killed in this country so late as the year 1730.

The wolf generally brings forth five or six at a litter, and occasionally eight or nine. The whelps are born blind, and the dam suckles them for about two months ; and soon teaches them to eat flesh, which she prepares by tearing it into small pieces. She then brings them young hares, partridges, and living fowls, which they at first play with and then kill. In about two months they follow their dam, who leads them abroad to some neighbouring pool to drink ; she conducts them back again ; or, when any danger is apprehended, obliges them to conceal themselves elsewhere. When they are attacked, she defends them with intrepidity ; losing every sense of danger, and becoming perfectly furious. She never leaves them till their education is finished, and they have acquired talents fit for rapine.

The wolf is larger and more muscular than the generality of dogs ; his colour a sort of brown grey, though there are black wolves, and white wolves are, we believe, sometimes met with. These animals are natives of almost all the temperate and cold regions of the globe.

Wolves are now but rarely seen in the inhabited parts of America ; yet the government of Pennsylvania, some years ago, allowed a reward of twenty shillings, and that of New Jersey of thirty shillings, for the destruction of every wolf. Tradition informed them what a scourge these animals had been to the colonies, and by these means they wisely prevented the evil. In the infant state of the colonies, it is said that wolves came down from the mountains, often attracted by the smell of the bodies of hundreds of Indians who died of the small-pox : but the animals did not confine their insults to the dead, they even devoured, in their huts, the sick and dying natives.

When pressed by hunger, the wolf, though naturally shy, becomes courageous from necessity : he then braves every danger, and will venture to attack even the buffalo. Sometimes whole droves of them descend upon the sheep folds ; and, scratching away the earth from under the doors, enter with dreadful ferocity, and put to death every living creature before they depart.

\*  
 “ By wint’ry famine rous’d, from all the tract  
 Of horrid mountains, which the shining Alps  
 And wavy Appenine and Pyrennees  
 Branch out stupendous into distant lands,  
 Cruel as death, and hungry as the grave !  
 Burning for blood ! bony, and gaunt, and grim !  
 Assembling wolves, in raging troops, descend ;  
 And, pouring o’er the country, bear along,  
 Keen as the north wind sweeps the glossy snow :  
 All is their prize.”

Although the wolf is the most gluttonous of quadrupeds, devouring even his own species when pressed by hunger, yet his rapacity does not exceed his cunning : always suspicious and mistrustful, he imagines every thing he sees is a snare laid to betray him. If he sees a rein-deer tied to a post to be milked, he dares not approach, lest the animal should be placed there only to entrap him ; but no sooner is the deer set at large, than he instantly pursues and devours it. Such, however, is sometimes his extreme cowardice, that, should the animal stand at bay, and act on the defensive, he will scarcely dare to attack it. A cow or goat, by turning upon and butting him with its horns, has often been known to put him to flight.

In Norway, wolves are often killed by means of a poisonous species of lichen, which the inhabitants put into the dead body of some animal and lay in their haunt. Sometimes they are caught by means of a hole dug in the ground, and covered with a trap door ; which falls and lets them in, and shuts again. In these pits, the cowardly animal has been found in a corner with other beasts, which his fears would not suffer him to touch. Instances have occurred even of peasants falling into these traps, and sitting quietly with a wolf till released.

The wolf has great strength, especially in the muscles of his neck and jaws : he can carry a sheep in his mouth, and run off with it without any difficulty. When reduced to extremity by hunger, we are told by Pontopiddan (who, by the bye, is not the best authority in the world) that he will swallow great quantities of mud, in order to allay the uneasy sensations of his stomach. His sense of smelling is very acute ; he scents the track of animals and follows it with great perseverance ; and the smell of carrion strikes him at the distance of nearly a league.

In 1764, an animal of this kind committed peculiar ravages in some particular districts of Gevandan, in Languedoc, and became the terror of the whole country. If the accounts then given in the Paris Gazette may be trusted, he was known to have destroyed at least twenty persons, chiefly women and children. With the usual aggravation of popular description, he was represented by some who had seen him, as far surpassing in size the rest of his species, and as striped somewhat in the manner of a tiger.

Buffon brought up several wolves. When young, or during the first year, (he informs us) they are very docile and even caressing ; and, if well fed, will neither disturb the poultry nor any other animals ; but, at the age of eighteen months or two years, their natural ferocity begins to appear, and they must be chained to prevent their running off and doing mischief. He brought up one till it was eighteen or nineteen months old, in a court along with fowls, none of which it ever attacked ; but, for its first essay, it killed the whole in one night, without eating any of them. Another having broken his chain, ran off, after killing a dog with whom he had lived in great familiarity.

The wolves, in the northern parts of the world, sometimes get upon the ice of the sea, during the spring, in quest of young seals, which

they catch asleep there. But this repast frequently proves fatal to them; for the ice, detached from the shore, carries them to a great distance from the land before they are sensible of it. It is said, that, in some years, a large district, is, by such means, delivered from these pernicious beasts, which are then heard howling in a dreadful manner, far out at sea.

In the wolf, there is nothing valuable but his skin, which makes a warm and durable fur. His flesh is so bad, that it is said to be rejected with abhorrence by all other quadrupeds; and no animal but a wolf will voluntarily eat a wolf. The smell of his breath is excessively offensive; since, to appease his hunger, he swallows, almost indiscriminately, every thing he can find; as corrupted flesh, bones, hair, and skins half tanned and even covered with lime. In short, the wolf is, in an extreme degree, disagreeable—his aspect is savage, his voice dreadful, his stench insupportable, his disposition perverse, his manners ferocious; he is destructive and odious to mankind while living; and, when dead, of little use.

**WOLF HUNTING.** This amusement is followed on the continent of Europe, and particularly in France; and at first view of the case, it might be supposed, that no animal could be better calculated to afford diversion before a good pack of hounds; but this does not appear to be exactly the case. As we have never been at a wolf hunt ourselves, we must be guided by what others have said on the subject; not, however, without giving our own opinion as opportunity may offer. Whatever appears like truth we are willing to adopt; but that which is at variance with common sense and reason, we generally reject: or, if we give it, we do not fail to qualify it with our own observations.

In the present case, we shall, in the first place, have recourse to the Rev. W. Daniel; for although on most sporting subjects he manifests the most egregious ignorance, yet, as, on the subject of wolf hunting, he only relates what he has been told, so we shall therefore, take the liberty of relating it after him. “The Compiler requested a friend (says he) who had his regular establishment of fox hounds in France, to inform him how far the chase of the wolf was successful, or likely to be so, when prosecuted by the vigour and speed of the English foxhound, and his reply was to the following purport:—‘You wish me to communicate my observations on wolf hunting, which I shall most readily do, but must first apprize you, that neither with my own hounds, which I took with me to France in 1774, nor with the hounds of the Count de Serrent, which

were under my direction some years before, did I hunt the wolf by choice. The Count de Serrent’s pack consisted of about thirty couple of French hounds, larger than the English stag hound, fifteen couple of them were kept for stag hunting only, and with the remainder they hunted the wild boar and the wolf. The first time I ever met the Serrent hounds was at a wolf hunt, where a bitch wolf had littered in some woods of the Count’s, far distant from the forest. The woods were nearly surrounded by the officers of the carabineers, each person with a double barrelled gun, some with small bayonets fixed, and all were loaded with ball. As soon as each sportsman had taken his station, the huntsman and hounds entered the wood; they found immediately; the hounds divided, and I, who was unarmed, tallyhoed the old bitch wolf, who went off for the forest in the most gallant style. My English halloo amused some of the French, but enraged others, who declared that if the huntsman had not fortunately stopped the hounds, they would have gone off with the old wolf, and this indeed was my intention. The stopped hounds were clapped back to those running the cubs in the cover, and which were said to be about three or four months old; they were taller than the fox, and shewed, by the looseness of their make, and the vast size of their bone, in their then infant state, what they would be when arrived at their full growth: that, however, was forbid, for all but one were shot that day, and the remaining one was killed the day following by one of the Count’s keepers. These cubs,

whilst hunted, never quitted the covers, nor was it supposed they had ever been out of them, for the forest towards which the old wolf pointed, was between four and five leagues distance from the woods where she littered. I often hunted wolf afterwards, and the result was, that the wolf was either shot in quitting the cover in which he was found, or by some keeper or person who accidentally saw him in his route, or he escaped by going off at one steady pace, until he left the hounds, horses, and men totally beat, and who were generally relieved by the hospitality of some curée, and enabled to return home the next day. It is asserted that the wolf, whose pace seems for the most part to be regulated by that of his pursuers, will stop when no longer pursued, and the hounds may attack him again the next morning; perhaps so, but will not the wolf be equally refreshed by his night's repose as the hounds? Admitting that the wolf does stop, he gives his enemies a fresh chance, because formerly there was scarcely a parish in France that had not one or more gamekeepers. The huntsman, who hunted the wolf related where he gave him up, how much he appeared fatigued, and which way he pointed, to the keepers, when his chase ended; they possibly guessed where the wolf rested that night, and by properly placing all the assistants they could collect, a shot was got at him when he broke cover, in the same manner as he had been fired at on the preceding day. Upon remarking this risk of being shot which the wolf had to escape, to a French gentleman, he assured me, that a friend of his, who kept hounds for the wolf only, never fired on the wolf until (unable to run any further) he turned upon the dogs, and this generally happened about the fourth or fifth day. This sounds strange hunting to us English fox hunters; but I declare to you, that I am not prepared to deny the fact."

In Colonel Thornton's "Sporting Tour through France, we find the following description of a wolf hunt:—"The intense heat of the day did not prevent us from throwing into the forest at four o'clock, and we soon roused a wolf, of which we had a view for five or six miles: however, there was no probability of killing him, but by shooting him, and this was not easily done, as the cover was extremely thick in underwood and heath, the avenues having been entirely neglected since the Revolution.

I heard several shots in different parts,

and some of them so near together, that I did not suppose them to be at the same animal: however, the cry returned, and I faintly saw something rush near me. The hunters came up and informed me, that they had just shot at a wolf; and one of the party said, in an exulting tone, he was confident that he had mortally wounded him.

I had twenty-one balls in my seven barrelled gun, and trusted that if I could get a shot the least clear of cover I should wound the game. We then took our respective stations in the *allées*, all agreeing, as is necessary, to shoot forwards. In about half an hour, I heard the cry no more, and therefore dashed on at a good rate for two miles, when I heard the hounds, but very faintly. Having placed myself in what I thought a likely pass, I heard a rustling, and soon discovered an animal listening, about sixty yards distant. Agitated as I was at the moment, I could not decide whether I should fire. I was certain of hitting with some of the balls; but as the cry continued to advance, I resolved to wait, and in a little time, *my gentleman* passed the avenue. He seemed jaded, and was evidently hit in the hinder parts. I then fired, but whether successfully or not, I could not tell. Running up to the boughs, where he had appeared, I found them cut, and, on carefully examining the range of the balls, I conceived that I had certainly wounded him; in consequence of which I remounted my horse, and tallyhoed so as to make the forest ring. In about ten minutes a couple and a half of my hounds appeared nearly together. Caustic and Consul, grandson and granddaughter of Merkin, of true Conqueror blood, seemed the most vermin. They flew counter down the avenue, but I hallooed them back; and, at this instant, three couple and a half, out of my four, came in, and were immediately followed by Vixen (a terrier) who appeared full as vicious. I capped them, and they went off at a rattling pace after the wolf, but still they were almost mute.

Having galloped on to the next avenue, I was joined by some straggling gentlemen, and at length by the huntsman, whom I informed of what had transpired. He was in raptures with my hounds, and exclaimed—"Par Dieu, Monsieur le Colonel, ce sont des veritables chiens, ils sont superbes. Ils tueront non pas seulement tous les loups, mais aussi le diable." If I hallooed like a madman, he certainly

was not behind me in blowing, for I really thought he would have burst either himself or his horn. The rest of the sportsmen, being furnished with horns, blew in concert, and the noise they made has never been out of my ears.'

Another shot proclaimed that the game was again seen, when he turned shorter and the hounds got nearer; and, on my representing to the gentlemen that our hounds would soon outrate him, they politely agreed to fire no more. The wolf was now frequently seen, and at every time the horns gave notice. He crossed an avenue that was tolerably clear, when Vixen, who had joined us, saw him, and, although just before jaded, the little devil got the scent and gave tongue. When she seemed to be near and teasing him, my hounds came up within two hundred yards of his jack, all in a sheet; and even some of the French hounds, which had given up the chase, now came in; one of them, between a Newfoundland dog and a deep mouthed Norman hound, worked very hard. The huntsman said, 'Monsieur le Colonel, ce chien Norman est un gaillard, il aime les loups. Il sera bientôt mort.' But (I replied) I fear he will wound my hounds severely, there are so few. If indeed the pack were here, I should not fear him. 'N'ayez pas peur, Monsieur le Colonel (rejoined the huntsman) je serai proche, et je lui flangerai un coup de mon carabine.'

At this moment, the wolf turned to us, when the terrier, having a decided advantage from the thickness of the cover, continued catching at his haunches. I hallooed, the huntsman blew away, and the game was now at the point of death, surrounded by his enemies. His tongue hung out, and he was evidently wounded in more places than one, as he could scarcely draw his near hind leg after him. After he had been tormented for some time by Vixen, he came to a sort of opening in the ride, but in crossing some deep ruts, he fell, and could not recover himself. The Norman hound and three others rushed in, and threw him on his back. He snatched, but they seized him by the throat and back, whilst Vixen had good hold of his haunch. I thrust the end of my whip in his mouth, and the huntsman coolly tied his nose, and drew his *couteau de chasse*, which I told him was unnecessary; the hounds being at him, he must soon expire.

Having blown our horns and hallooed till we were almost dead with drought, we

tied our horses to some trees, and sat down whilst the wolf was dying. The huntsman said it was a '*gros loup de quartier année*;' and I observed he had a famous set of grinders and good dog teeth.

He had received from the first fire of M. de Beaumont, a small pistol ball through the upper part of his back, and one buck shot had grazed his neck. My balls, being rifled very neatly, were easily known; two of them had entered the fleshy part of the thigh, and a third, which crossed the kidneys, seemed to have given the mortal wound, as, without that, the huntsman said, he would have stood much longer: his brush had suffered from some balls, which almost every gentleman present asserted to have been his own.

Having opened our canteens and taken some refreshment, I ordered the carcase of the wolf to be thrown to the hounds, and the greatest part of it was soon devoured; but the French hounds would not touch it. On examining the dogs, we found that one of Consul's ears was almost bit off, Caustic was sadly cut on the side of her face, and the rest a little injured. Vixen has escaped with only a bloody nose: that was indeed a severe wound for a terrier, but she did not seem to mind it; and indeed they all suffered much less than I expected.

Thus terminated about ten o'clock what I had been so anxious to see, a wolf hunt, and I had now ascertained what might be done with foxhounds." This wolf hunt took place in the forest of Berci.

Colonel Thornton says the chase of the wolf has this advantage over all others, that, while it is of itself extremely sporting, it is, at the same time, very useful and often necessary; nothing being more destructive than those animals which have frequently desolated the country, either by surprising the flocks, or by attacking children, whom they carry off and devour. Those who have lived for any time at a distance from large towns (in France) must know how formidable is the neighbourhood of wolves, particularly when they have young ones to support. These animals are extremely ravenous, and almost always hungry; when they find nothing to satisfy their appetite in the woods, they spread themselves over the country, entering villages, and seizing, with incredible dexterity, whatever is capable of appeasing their hunger. They lie in wait for their prey, and scarcely ever fail to attack it the first favourable

opportunity that presents itself. They, besides, make dreadful havock among the deer in the forests, particularly in winter. The public interest, as well as their own, should therefore induce the lovers of the chase to make war on this animal.

Before we proceed on this subject (observes Colonel Thornton) it may perhaps be necessary to observe, that the hunting of the wolf being entirely confined to the countries of the Continent, and particularly to France, many of the technical terms employed in this interesting sport are of such a nature, that it is impossible to render them into the English language. The original, will be therefore, in many cases, retained.

*Terms employed in Hunting the Wolf.* Wolves are divided, according to their age, into cub-wolves, old wolves, and wolves: their age may be discovered by their feet, and their footsteps are called the track of the wolf.

When the wolf goes a gentle pace, without hurrying himself, he is said to go with confidence.

When he goes in quest of food, it is said he is seeking food, he is going to feed on carrion, he seized the carrion, he glutted himself with carrion.

In the season of copulation, wolves are said to be at heat.

When the wolf has covered the female, it is said, the wolf has coupled, the wolf has coupled or lined the she wolf.

When they have produced young, they are called a litter of young wolves.

We say, the head, the teeth, the skin, of the wolf.

The nipples of the she wolf are called teats.

The places where they have scratched up the earth, are called *dechaussures*, and we say the wolf has torn up such a place.

The place where a wolf lies is called his kennel.

When we see the wolf of which we are in chase, we cry *Veletau, Veletau! harlou*, (from *au loup*) *chiens! harlou! velec aller! velec aller!*

We say the howling of wolves; to howl for wolves is to entice them to you, that you may shoot them in the night.

*Manner of distinguishing a he-wolf from a she-wolf by the feet.*—The he wolf has a larger and thicker foot than the she-wolf. When the wolf is young, his foot expands as he walks; when he grows old, his foot is narrower, both before and behind; his claws are thick, long, and close; his heel thick and broad, and the fore part of the

foot thicker than the hinder part. When the wolf goes with assurance, that is, when he walks his ordinary pace, he commonly puts the hind foot into the step or track of the fore foot. It is easy to perceive this in wet weather or in snow; but when he goes at a trot, the hind foot keeps at the distance of three fingers from the fore foot. The she-wolf has a longer and narrower foot than the male; her heel is smaller and closer; and her claws are not so strong.

*Manner of discovering the places where she-wolves have littered.*—In the month of August or September, the cubs having acquired a little strength, begin to walk about, and to sport among the thickets; and, in particular, take notice of all the places near where there are marshes. The females usually seek those situations, as well for the convenience of retreat, as to allay the burning thirst caused by the season, and the food on which they subsist. It is commonly in the morning and evening that the young wolves go to the marshes. You may take young dogs to the spot, but you ought to have one in particular that is well trained to that kind of search; in beating the wood, he will not fail to discover the wolf, he will even pursue him, rouse him, and follow him to his haunt; when there, you should caress and encourage him, to induce him afterwards to go and pursue him alone. The movements of the old dog will animate the younger; you should therefore sometimes send him forward to excite the others, and afterwards you may call him behind to see whether the young dogs are capable to go by themselves; and as the young wolves will not easily quit their situations, you must make the dogs return to the charge and follow the scent, and then, after having encouraged them, call them off.

To train young dogs to hunt the wolf, the sportsman must proceed in the following manner:—He should take them to the wood every two days, towards the places which he supposes to be frequented by the wolves; he cannot fail to discover them, because the he or she-wolf always goes in the morning to the cubs, and then retires into other thickets to deceive the hunters; it is then that you have an excellent opportunity of employing blood hounds to advantage. The thickets chosen by the wolves for their retreats are easily known; near them there are always fragments of their prey, by which they are betrayed, as bones of horses, skeletons of

dogs and other animals. It is besides, easy to remark, whether the grass about the spot is trodden, which is a sign that the young wolves have come thither to lie down.

*Equipage for Wolf Hunting.*—In this respect, it is not necessary to go to any great expense, as twenty-five or thirty hounds are sufficient. They ought to be of a good size, to have a grey coat, and to be marked with red about the eyes and on the cheeks; by these marks you may discover their greater or less degree of eagerness in the chase. You ought likewise to have six or eight leashes of large stout greyhounds, and some good whelps. They encourage each other, and attack the wolf with the greater vigour. A good whipper-in also is highly necessary, two attendants for the blood hounds, two for the hounds, and one to slip the greyhounds.

Your bloodhounds for hunting the wolf cannot be too good; they ought to be bold, lively, and full of ardour. When they possess all these qualities, you derive from them a two-fold advantage; for besides that which you enjoy in the chase, they likewise serve to train other dogs. A good sportsman ought to be prudent as to the service he requires of his dogs, and he should be very careful of them, for the chase of the wolf is more fatiguing to the bloodhound than any other kind, the wolf being naturally crafty and mistrustful. From the moment that he perceives they are after him, he is constantly going, and when he finds himself pursued, he changes his abode, and leads his pursuers a very fatiguing chase. It is therefore advisable to spare the blood hounds, and to make them serve alternately. A day of rest gives them fresh ardour, and enables the sportsman to hunt with more satisfaction.

*The Search of the Wolf.*—The wolf is tried for in various ways, according to the difference of the seasons. If it be in winter, you should go to the wood some time before sun rise, because that is about the time that the wolves repair to it. In summer, there is no occasion to go so early, because these animals frequently stay among the corn, and do not return to the wood till the day is advanced. Therefore, without being in too great a hurry, it will be sufficient to beat twice along the skirts of the thicket towards the cover, and if you meet with nothing, it will be advisable, on your return, to beat the contrary side.

There is a considerable difference between trying for the stag and the wolf.

The former remains a long time in the thickets; sometimes he does not even leave them to pass the night in the open fields; but the conduct of the wolf is the reverse. Hunger, it is said, drives him out of the wood; and, as he subsists entirely by carnage, he will frequently approach farms, villages, and even towns, and seize whatever falls in his way. If by accident, he remains a considerable time in a thicket without quitting it, even during the night, it is only when he has taken a deer, or some animal that he is occupied in devouring.

When the assistant huntsman shall have arrived with his *Limier*, or bloodhound, at the place containing the object of search, he must loosen the leash, and make his dog advance before him more than half the length of it, continually caressing him and saying—*Va outre Ribaut hau, mon valet! hau lo lo lo lo! veleci! veleci allé, mon petit!* It is well frequently to repeat these words, because nothing more encourages and animates the dog in the pursuit. You must take good care that the bloodhound may not take the scent of some wolf that has entered the forest by some ravine or great road; and when you perceive that the dog is about to acknowledge the scent, and that he puts his nose either to the branches or the tufts of grass, you must encourage him, for dogs are not naturally very eager after the wolf; and I have remarked (says Colonel Thornton) that they are not very eager in quest of him. Besides (continues the Colonel) the scent of the wolf does not continue more than two or three hours; and to be enabled to unkennel him, he should not have passed more than two hours; otherwise the bloodhounds will scarcely be able to hunt up to him, especially if it be on a beaten dry road.

When a huntsman perceives that his dog has got upon the scent of a wolf, he should encourage him in these terms:—*What! is he there, Boy?—Hau l' amy après, veleci y dit vrai;* and he should frequently repeat them to encourage the dog, which he must continue to follow, either by the side of the way, or in the *faux-fuyant*. Too much attention cannot be used on these occasions, because there is always reason to apprehend, lest the scent should grow too weak, and lest the bloodhound should relinquish it at the first crossway to which the wolf may have betaken himself. It is to be observed, that when the wolf passes a crossway, he always stops there for some time, either to

dung, or to make water against some bush of broom, or furze, or a tuft of grass. He then immediately scratches up a spot on the surface of the ground four feet in extent, tearing up the turf backwards with his claws. He then continues his course, and sometimes conceals himself at a considerable distance; sometimes he likewise endeavours to give his pursuers the slip, and instead of following the road takes another, and turns towards the thickest part of the wood with a view to enter it. For this purpose, he takes the first double he comes to, or some favourable passage, which happens principally when the earth is moist. It is at such times that the sportsman should be careful to train the hound to the scent, at about half the length of the line, and to encourage his bloodhound more and more. If it be still early in the day, he may follow the drag with little noise, and withdraw secretly to proceed before. He should observe, that, during this time, the hound may surprise the wolf, either by some *faux-fuyant*, or by some glade, by which he may have penetrated into the recesses of the wood, for wolves have different paces, according as they are more or less hungry. When driven by hunger, they are almost incessantly on foot, and proceed forward till they have found something to eat; but when they have glutted themselves, they frequently retire into the first thicket they come to, provided they find favourable places for their kennel, as hollics, fern, and other shrubs.

If the sportsman be at the forest on a hunting day, he will content himself with ascertaining whether the wolf has entered the thicket. He will endeavour to discover the little avenue or glade, by which he may have entered it; he will caress his bloodhound, and afterwards break the branches at the entrance of the thicket. After he has convinced himself that he has discovered the track of the wolf, he will return to the company to make his report; but if he had no other intention than to exercise his dog, or if it is a considerable time since he dislodged the wolf, he may, as soon as he has reconnoitred, return to the inclosure to discover the traces, then push on and dislodge the wolf, and follow the drag to the haunt, caressing his bloodhound, and continually using the above mentioned terms. If the bloodhound be young, his ardour will abate on approaching the haunt, because the scent of the wolf naturally inspires dogs with terror, and there are very few which

dare venture to follow him by themselves. It is therefore necessary to speak to him a good deal, in order to animate and embolden him to pursue, and he should be much caressed on the track. With regard to the haunt, I shall observe here, that wolves frequently change according to the difference of the seasons; for instance, in summer, they choose an open place among the grass, on which the sun shines a little; but in winter they repair to the recesses of the woods or thickets, among heath or fern. They seldom fix their abode beneath very high trees, excepting they find there very thick bushes, or abundance of fern or rushes.

*In what manner it may be discovered that the Bloodhound has got scent of a Wolf.* It is very difficult to get sight of a wolf on account of his great speed; he even scarcely leaves behind him any traces, excepting in winter in a white frost, or in summer, when there is much dust. In all other circumstances, you may be said to proceed with no great certainty; and if a person has not had long experience in the chase, he frequently takes many a step in vain. There are, however, certain signs, by means of which you may discover the object of the bloodhound's movement, and consequently distinguish whether it is a wolf or some other animal, of which the dog has got the scent. If it be a wolf, he will not fail to go and smell at the branches and the grass the wolf has touched, and will immediately proceed in pursuit of him. If the wolf makes a good impression on the ground, and the dog has any scent, you will see him pursue briskly, provided you take care to encourage him from time to time on the drag. But if the wolf passed very early, and you are not on the spot in good time, the bloodhound will lose the scent, particularly if the wolf proceeds in a right line, and is gone to a considerable distance; for a dog must have an excellent nose to discover a wolf that has passed longer than two hours and a half or three hours; and he is liable to change if there be any deer in the thicket, or if he have not been exclusively trained for wolf hunting. When the sportsman perceives, by the manner of the dog, that it is the track of a wolf which he has discovered, he must endeavour to find out whether the animal is alone or in company. They generally go in pairs; it is only in seasonable weather that he can discover their number and quality, by examining their footsteps with attention, conformably to

what has already been stated on that subject.

*Manner of making a report of the Discovery of a Wolf.*—It appears that it is not very easy to distinguish the track of wolves from every other animal. A sportsman should possess much experience and be capable of just observation, to be able to make an accurate report.

A report is commonly made in the following manner :

I believe I have discovered the track of one or two wolves ; or of a he and a she wolf ; or of several ; according to the indications one has observed : they came from such a thicket, or they went in quest of food towards such a village ; they killed so many deer, which I found in following them, and they afterwards repaired to such a thicket. I continued the search ; and as I imagine that their direct road lies from such a thicket, where I have reason to believe they are, to such other thicket, there is a fine opportunity for driving him into the open country, and an advantageous situation for placing greyhounds.

*Manner of placing Greyhounds.*—The greyhounds for the wolf are divided into three classes, the *Levriers d'Estrée*, *Levriers Compagnons*, (likewise called the flank greyhounds) and *Levriers de Teste*. There ought in general to be two leashes of each kind, each leash being composed of two or three greyhounds. The two *laisses d'estrie* are first placed by the side of the thicket, near the spot at which you imagine the wolf will break. These two leashes should be about five or six hundred paces distant from each other, more or less, according to the situation of the place. Each leash should be supported by a horseman, who should take care to conceal himself, with the dogs, on the skirts of the wood down the wind, to push the wolf when the dogs are let loose and to make him take the open country. At five or six hundred paces from the former, and about half way between the two thickets, must be posted the flank greyhounds ; the two relays of these are placed opposite to each other for the wolf to pass between them. Attention must be paid to keep these still more concealed than the former, lest the wolf should perceive them, and the valets must attend to loose them as soon as the wolf is ready to pass. The *levriers de teste* should be placed near the thicket which the wolf is expected to make for ; and when he is observed to approach pursued by the dogs, the *levriers de teste*

should then be brought forward, and let loose upon the wolf. The latter being stronger and more furious than the others, soon bring the wolf to bay ; the valets should then halloo up the bloodhounds, and hasten to the wolf as speedily as possible. As soon as the dogs hold him to bay, the valets must take care to provide themselves with short thick sticks to thrust down the wolf's throat the moment they are within reach ; because that animal, never quitting any thing that he once seizes upon, the stick which is presented to him protects the dogs from the wounds which he might otherwise inflict. The huntsmen must then employ their hunting knives, observing the precaution, when they approach to stab the wolf, to have one hand always at the point of the knife, lest they should hurt the dogs. When a favourable moment for stabbing the wolf presents itself, the knife should be thrust through his body near the shoulder.

*Manner of Hunting the Wolf with Hounds.* To succeed in this mode of hunting, the greyhounds must, above all things, be placed in the manner before described. You must then post on the side of the thicket at which you wish to prevent the wolves from issuing, ten or a dozen men, each provided with a rattle to be employed on the occasion. Care must be taken to station them at the distance of sixty paces from each other, more or less, according to the extent of the thicket. When every thing is ready, the leader gives the order, and the dogs are immediately taken to the *brisées* to be let loose. The whipper-in holds the dogs to the *brisées* in the thicket, to make them take the scent, and then conducts them along the track towards the spot where he supposes the wolves reside, continually encouraging them by the cries of *hala ila la tayau veleci aller*. He blows his horn from time to time, to animate them in the pursuit. The noise of the dogs will perhaps make the wolf quit his kennel long before they come up ; but sometimes he waits till they are close to him before he breaks. If the huntsman perceives him, he must then call to his dogs in these terms:—*Veletlau ! veletlau ! harlou ! harlou ! veleci aller !* He will then sound his horn to make them follow the traces, and then cry *Harlou ! chiens ! harlou ! veleci aller !* When the dogs have taken to the traces, they will not fail to rouse the wolf, and pursue him with eagerness ; the huntsman will then sound his horn to animate them still more.

The wolf, thus pursued, will perhaps hang cover before he breaks it, that he may obtain the advantage of the wind in his flight; but the men stationed to keep him in will make use of their rattles, the sound of which will head him, and make him go off without having the advantage of the wind. While the wolf is thus in suspense concerning the way he shall take, he is briskly pushed by the dogs, supported by the huntsman, who will incessantly keep crying—*Ha y fuit les chiens, y fuit la! ha! ha!* He will then sound two blasts, and again begin hallooing—*Hou! veleci aller! veleci aller!* At length, the wolf, finding himself pressed by the dogs, the cries of the hunters, and the noise of those stationed to keep him in, resolves to escape by the place where he hears no noise, which is precisely the part next to the open country. He stops a moment at the skirts of the wood, to observe whether he can see any person, and immediately sets off to cross the plain. He is suffered to advance about one hundred paces, when the *levriers d'estrie*, and afterwards the others, are let loose upon him, on the plan already mentioned. Two horsemen at the same time ride after him, to oblige him to continue his course, as it is of great consequence that he should be kept in it; but for this, he would escape, as the attempt to run down a wolf is scarcely ever made. To command success in the latter case, you ought to be perfectly sure of your relays, that the dogs were trained exclusively to the chase of the wolf, that there were neither deer nor boars in the forest. This kind of chase would, besides, be long and fatiguing, because the wolf is rarely blown; he runs a long time, never ahead, almost constantly viewing him for six or seven hours together. The greyhounds, placed in ambush, greatly abridge this chase, and likewise render it more amusing and certain to the spectators.

As soon as a wolf is taken, he should be given up to the hounds which come up, almost immediately, because otherwise the greyhounds would attack the hounds. It is therefore advisable that they should be taken off immediately and coupled, to return and go in quest of another, for it is easy to take several wolves in one day. When this is intended to be done, each should resume his former position; as for those who are stationed to prevent the animal's escape, they must not, on any account quit their posts till they receive orders to that effect.

When the wolf is expiring, his death is announced by three loud blasts of the horn. The huntsman alights and caresses the dogs to excite them to worry him. It is the duty of the whipper-in to cut off the animal's right foot, which he presents to the commander of the company.

*Manner of Chasing the She-wolf and the Cubs.*—Nearly the same things are observed in the chase of the female as of the male; the same method of pursuit, and the same cries or halloos are employed: but the young wolves are chased with less precaution, and are attacked in their caverns by the dogs. As soon as the dogs have discovered them, they are seized with fear, and run from one side to the other, without ever quitting the thicket.—The whipper-in must follow and encourage the dogs by three notes from his horn, and must speak briskly to them in these terms:—*Harlou! harlou! hou veleci!* This gives the dogs fresh spirits, courage, and strength, and they rush upon the young wolves with renewed ardour. When they have overtaken them, the huntsman dispatches them with his hunting knife, always observing the precaution mentioned above, lest the dogs should sustain any injury.

If there are in the pack any young dogs, which have not before been in the chase, they might be made to begin by chasing the young wolves in company with old steady dogs. In their beginnings, they ought to be animated and encouraged by frequent caresses with the hand; and when the young wolves are taken, they should be made to approach, and to ruffle on them and pull them.

When the chase is over, a retreat is sounded, all the dogs are collected, and the wolves that have been taken are carried away.

*The Blooding of the Wolf.*—The blooding of the wolf differs very much from that of the stag and other beasts, which are given to the dogs on the spot. The scent of the wolf is extremely strong, and the dogs would not taste the flesh if care were not taken to disguise it. I have frequently remarked, (says Colonel Thornton) that dogs which manifested abundance of ardour in the pursuit, durst not venture to approach the animal to trample upon him when killed. Nothing but great precaution and repeated caresses can overcome their aversion to the flesh of the wolf. The following is the manner in which it is prepared:—

The wolf must first be skinned and the

entrails taken out; the head is then cut off, but the skin and ears are left upon it; the quarters are then cut off, and are baked with the body in a very hot oven. While the whole is roasting, a quantity of small pieces of bread are put into one or more tubs, into which are thrown the quarters of the wolf, cut into pieces, as soon as they come out of the oven. Upon this is then poured a large pot of boiling water, into which, while heating, have been put three or four pounds of grease, and the whole is well stirred and mixed. When the whole is soaked, it is emptied out of the tubs upon a piece of sacking made for the purpose, and stirred again, that the mixture, which is still warm, may be in a state fit to be eaten by the dogs. When every thing is ready for the blood-ing of the pack, the whipper-in receives the switches from the hands of the first valet. He presents two to the commander of the company, who gives one to the master to whom he belongs. The switches being distributed, the kennel is opened, and the huntsman sounds the tune customary on such occasions. At the same time the skin and head of the wolf are laid before the dogs, that they may become accustomed to that animal. After eating the mash, the roasted body of the wolf, to which the head has been affixed, is presented to them at the distance of thirty paces. The best way of making them eat it, is to shew it them at the point of a fork, and to animate them with words and the sound of the horn, and they will not fail to fall upon it with eagerness.

The foregoing is the French manner of preparing the animal for the winter; the method employed in summer is somewhat different. The quarters are roasted and cut in pieces as before; but, instead of water boiled with grease, two or three pailfuls of milk, into which have been put a quantity of very small pieces of bread, or rye flour, are poured over them; the whole is mixed together, and this mess is given the dogs in the same manner as the other. They eat it willingly, and it is extremely refreshing for them. The body is afterwards given them in the manner before described.

Thus much for the French mode of treatment; their hounds will not bear any comparison with those of the English breed. The former are deficient in animation, and possess a very small share of mettle; while, on the contrary, such is the blood of the well bred English hound,

that he would instantly break up any wolf on seizing it.

The breeding of hounds, as well as horses, in England, has been a primary object among sporting gentlemen, which accounts for their exclusive superiority in this country. Even with this advantage in our favour, I do not approve of the plan (says the Colonel) of deliberately taking the game, when killed, from the hounds: this operates as a check to them, and creates a shyness. Hounds, upon killing their game, should be allowed and encouraged to eat it up, while their spirits are roused and the blood of the animal is warm: but as wolf is a scent that some hounds shew a fear of, they should be encouraged, by all means, to run, kill, and devour it; and in no way should their ardour be checked, even from the unken-nelling to the death."

Such is the account given by Colonel Thornton of the mode of pursuing the wolf in France.

At the present moment, wolves are seldom pursued in that country, without the powerful assistance of fire arms to aid the exertions of the hounds.

The wolf hunting of America is by no means systematic. When a wolf shews himself near the cultivated parts of that country, he is pursued night and day till he is destroyed or makes his escape. The following interesting account, though tolerably well known, perhaps, on this occasion seems to be worth repeating:—

Soon after Mr. Putnam removed to Connecticut, the wolves, then very numerous, broke into his sheep fold, and killed seventy-five sheep and goats, besides wounding many lambs and kids. This havock was made by a she wolf, which, with her annual whelps, had, for several years infested the vicinity. The cubs were commonly destroyed by the vigilance of the hunters, but the old one was too cunning to suffer any one to approach her within gun shot. Upon being closely pursued she would generally fly to the western woods, and return the next winter with another litter of whelps.

This wolf at length became such an intolerable nuisance, that Mr. Putnam entered into a combination with five of his neighbours to hunt alternately until they could destroy her. Two, by rotation, were to be constantly in pursuit. It was known, that, having lost the toes from one foot, by a steel trap, she made one track shorter than the other. By this pe-

culiarity, the pursuers recognised, in a light snow, the route of this pernicious animal. Having followed her to Connecticut River, and found she had turned back in a direct course towards Pomfret, they immediately returned, and by ten the next morning, the hounds had driven her into a den, about three miles from Mr. Putnam's house. The people soon collected, with dogs, straw, fire, and sulphur, to attack the common enemy. With this apparatus, several unsuccessful efforts were made to force her from her den. The hounds came back badly wounded and refused to return. The smoke of blazing straw had no effect; nor did the fumes of burnt brimstone, with which the cavern was filled, compel her to quit her strong hold. Wearied with such fruitless attempts (which had brought the time to ten o'clock at night) Mr. Putnam tried once more to make his dog enter, but in vain. He proposed to his negro man to go down into the cavern and shoot the wolf; but the negro declined the dangerous service. Then it was, that Mr. Putnam, angry at the disappointment, and declaring that he was ashamed to have a coward in his family, resolved himself to destroy this ferocious beast, lest she should escape through some unknown fissure of the rock. His neighbours strongly remonstrated against the perilous enterprise; but he, knowing that wild animals were intimidated by fire, and having provided several strips of birch bark, the only combustible material which he could obtain that would afford light in this deep and darksome cavern, prepared for his descent. Accordingly, divesting himself of his coat and waistcoat, and having a long rope fastened round his legs, by which he might be pulled back at a concerted signal, he entered head foremost, with the blazing torch in his hand.

The aperture to the den, on the east side of a very high ledge of rocks, was about two feet square; from thence it descended obliquely fifteen feet, then running horizontally about ten more, it ascended gradually sixteen feet towards its termination. The sides of the subterraneous cavity were composed of smooth and solid rocks, which seemed to have been separated from each other by an earthquake. It was in no part high enough for a man to raise himself upright, nor in any part more than three feet in width.

Having groped his passage to the hori-

zontal part of the den, the most terrifying darkness appeared in front of the dim circle of light afforded by his torch. He cautiously proceeded onward, came to the ascent, which he slowly mounted on his hands and knees, until he discovered the glaring eye-balls of the wolf, which was sitting at the extremity of the cavern. Startled at the sight of the fire, she gnashed her teeth, and gave a sullen growl. As soon as he had made the necessary discovery, he kicked the rope, as a signal for pulling him out. The people at the mouth of the den, who had listened with much painful anxiety, hearing the growling of the wolf, and supposing their friend to be in the most imminent danger, drew him forth with such celerity, that his shirt was stripped over his head, and his skin was severely lacerated. After he had adjusted his clothes and loaded his gun with nine buck shot, and holding a torch in one hand and his gun in the other, he descended a second time, when he drew nearer than before. The wolf, assuming a still more fierce and terrible appearance, howling, rolling her eyes, snapping her teeth, and dropping her head between her legs, was evidently on the point of springing on him. At this critical moment he levelled and fired at her head. Stunned with the shock, and suffocated with the smoke, Mr. Putnam immediately found himself drawn out of the cave; but having refreshed himself, and permitted the smoke to dissipate, he went down the third time. Being come within sight of the wolf, who appearing very passive, he applied the torch to her nose: perceiving her dead, he took hold of her ear, when kicking the rope, the people above, with no small exultation, drew them both out together.

**WOLVES' TEETH.** Those so called, are the teeth of the horse, enlarged by a preternatural growth, so as to lacerate the fleshy internal part of the cheek by the prominence of their ragged edges, or by the upper grinders overhanging the lower; they catch the wrinkled parts (called flaps) between them in the act of mastication, occasioning so much pain, that some horses are considerably reduced in flesh by a compulsive abstinence. With horses labouring under such infirmity or imperfection, there is no relief to be obtained, but from a proper file, and the hand of a steady operator. Some persons use the mallet and chisel.

**WOODCOCK.** The weight of the woodcock is from twelve to fourteen ounces, though instances have occurred where they have weighed several ounces more. The bill of this bird is three inches in length, dusky towards the end, reddish at the base, and hollowed lengthwise with deep furrows; the upper mandible hangs over the lower, and forms the round point of the bill; and nature has given at this extremity, an additional organ, appropriated to its mode of life—the tip is rather flesh, than horn, and appears susceptible of a sort of touch, calculated for detecting its prey in the moist earth; the tongue is slender, long, sharp, and hard at the point; the eyes large, and placed near the top of the head, that they may not be injured when the bird thrusts its bill into the ground. The shape of the head is remarkable, being rather triangular than round; the ears are placed very forward, nearly on a line with the corners of the mouth; from the bill to the eyes is a black line; the forehead is a reddish ash colour; the crown of the head, the hind part of the head, the back, the coverts of the wings, and the scapulars, are prettily barred with a ferruginous black, red, and grey; but on the head, the black predominates; the under eye lid, white; the chin, ash colour; fore part of the neck, yellowish, marked with dusky minute dashes; the under parts of the body, dirty white, barred with numerous transverse dusky lines; the quill feathers are dusky, marked on the outer web, with triangular rufous spots; and the same on the inner web close to the shaft. The tail consists of twelve feathers, dusky or black on the one web, and marked with red on the other; the tips above are ash coloured; below, white. The shades of the plumage of this bird are so blended as to resemble, very strongly, the withered stalks, leaves, &c. which form the back ground of the scenery where it is generally found. The legs and toes are pale flesh coloured brown.

The female woodcock may be distinguished from the male by a narrow stripe of white along part of the exterior web of the outermost feather of the wing; the same part, on the outermost feather of the male, is elegantly and regularly spotted with black and reddish white. In the bastard wing of each sex is a small pointed narrow feather, very elastic, and used occasionally by painters as a pencil.

The woodcock, during summer, is an inhabitant of Norway, Sweden, Lapland, and other northern countries. But when winter approaches, the severe frosts of those high latitudes, by depriving it of food, force it southward to milder climates.—These birds arrive in Great Britain in flocks, sometimes as early as September, but not in great numbers till November or December. They generally take advantage of the night, being seldom seen to arrive before sunset. The period of their arrival depends much upon the prevailing winds; for, as they are unable to struggle with the boisterous gales of the northern ocean, they wait for the advantage of a favourable wind. When they have had bad weather to encounter on their passage, they are frequently so much exhausted on their arrival as to remain on the same spot many hours, almost helpless, and much reduced in flesh, by the fatigue of their voyage. In very stormy wea-

## W O O D C O C K

ther, we are told, they occasionally take refuge in the rigging of vessels at sea, and that numbers are frequently lost on their passage.

Woodcocks are found much farther to the south than is generally supposed : in fact, in their periodical wanderings or migrations, these birds are actuated by hunger ; wherever their food is to be obtained, woodcocks are likely to be found, as, although they breed, for the most part, in the colder regions of the north, a warmer climate seems no way injurious to them, provided their food is to be obtained in plenty.

The greater part of them leave this country about the latter end of February or the beginning of March. They retire to the coast ; and, if the wind be favourable, set out immediately ; but, if contrary, they are often detained for some time, and thus afford good diversion to those sportsmen who reside near the shore.

Woodcocks feed on worms and insects, which they search for with their long bill, in soft ground and moist woods, flying and feeding principally towards evening, and also by moonlight.

Mr. Bowles has described the manner in which the woodcock feeds from those he saw in the Aviary at St. Ildephonso in Spain : “ There was (he observes) a fountain perpetually flowing to keep the ground moist, and trees planted for the same purpose ; fresh sod was brought to them, the richest in worms that could be found. In vain did the worms seek concealment when the woodcock was hungry ; *it discovered them by the smell* ; stuck its bill in the ground, but never higher than the nostrils, drew them out singly, and raising its bill into the air, it extended upon it the entire length of the worm, and in this way swallowed it smoothly without any action of the jaws.

This whole operation was performed in an instant, and the motion of the woodcock was so equal and imperceptible, that it seemed doing nothing ; it never missed its aim ; for this reason, and because it never plunged its bill beyond the orifice of the nostrils, I concluded that *smell* is what directs it in search of its food.”

But Mr. Bowles was mistaken. The subject is placed in a very clear and very correct point of view by the author of the Shooter's Companion ; whose observations on the subject we shall transcribe : —“ An erroneous notion generally prevails (says he) that the woodcock lives by suction ; which has probably arisen from the bird's being occasionally observed to thrust his long bill into the earth. As I am not aware (he continues) that any naturalist has truly described the mode of feeding of the woodcock, I shall relate a few particulars from actual observation. Most writers observe, that, to obtain food, the woodcock thrusts his long bill into the ground, and thus coming in contact with small worms and insects, he is enabled, by means of his semi-serrated beak, to squeeze the dirt out of his mouth, and then swallow the food. It is possible, certainly, that the woodcock may, by *boring*, obtain small worms and insects, and, after cleansing them from the dirt, swallow them ; but his general and regular mode of feeding is as follows :—having pierced the ground with his long bill, and shaken the surrounding earth, all the worms in the immediate vicinity make their way to the surface, and are greedily swal-

## W O O D C O C K

lowed. If a person force a stick or spade into the ground, and move it about, he will quickly perceive the worms within reach of the motion appear at the surface, manifesting great alarm and eagerness to escape from danger: instinct, therefore, no doubt, impels the woodcock thus to procure his food.—In a severe frost, this bird is driven to shades and protected places, where the ground still remains sufficiently soft to admit of the operation of *boring*. The woodcock appears to crush the worm to a jelly as it passes up the bill, and, either from this circumstance, or from extraordinary powers of digestion, whatever the bird swallows seems to become, almost instantaneously, that exquisite delicacy of the table, known by the name of *the trail*. If a woodcock be flushed, while feeding, in the very act of swallowing a worm, and be shot at the distance of thirty yards from the spot whence he rose, the worm will be found changed into a jelly-like substance, the *trail* I have just mentioned. The woodcock is seen to feed early in the morning, and at dusk in the evening; but this must not be understood in a literal sense. The bird is on the wing at the very dawn of the morning, and feeds as soon afterwards as he can discover food; he will then generally continue in the place where he has fed, if sheltered, or seek the protection of some cover or hedge; and, if undisturbed, will remain in the same situation till late in the afternoon, when he feeds again, and afterwards takes a short flight or two to his resting place for the night.”

The sight of the woodcock is indifferent in the day time, but he sees better in the dusk of the evening and by moonlight; and it may also be remarked that woodcocks will lie better the day following a moonlight night, than when it has been preceded by a very dark one: the reason is obvious—the bird has been enabled by the light of the moon to make a plentiful repast, and the next day is lazy and unwilling to fly; whereas, when the darkness of the night has rendered it impossible for him to satisfy the calls of hunger, he is constantly uneasy, and on the alert in search of food, which he never attempts to seek in the day time, but when necessity compels him.

M. Baillon says he has frequently remarked that there are two kinds of woodcocks:—the first that arrive are the largest, their legs are grey, slightly inclined to rose colour. The others are smaller, their plumage similar to that of the large woodcock, but their legs are blue.

But it would appear that there are three different sizes of woodcocks. Those which first make their appearance in this country are the largest; they fly heavily, and their heads appear to be muffled, especially the under parts, with short feathers: and the general cast of their plumage appears lighter or more inclining to grey, than the smaller birds. The most numerous tribe, which arrive in November and December, are rather smaller, their heads less, the feathers smoother, and the bill somewhat shorter. Woodcocks that come about Candlemas are also small, and differ in their manner of flying; they rise more rapidly, take longer flights, are more difficult of approach, and consequently not so easily shot.

Upon the coast of Sussex, woodcocks have been seen on their first

## W O O D C O C K

arrival, in the church yards and even in the streets of Rye, in considerable numbers. At their first coming on that coast, they are commonly poor, as if wasted by their long journey, and are sometimes scurfy, though not so much as before their return in the spring; and it is remarkable that when the woodcock first arrives, the taste of its flesh is quite different from that which it afterwards assumes: it is very white, short, and tender, and seems to have little or no blood in it; but after it has been in this country a considerable time, the flesh becomes more tough, stringy, and fibrous, like that of domestic fowls. If a woodcock is shot just before his departure, he bleeds plentifully; whereas, at the beginning of winter, scarcely any blood flows from the wounds: hence it would seem, that in those countries where they have their summer residence, they subsist upon different nourishment to what they find here.

By the short flights which these birds generally take when flushed in our woods or covers, they do not appear fond of using their wings long together; yet they certainly visit us from places far distant; and first appear on the eastern coast of Scotland: they do not arrive in Breadalbane, a central part of the kingdom, until the latter end of October, or beginning of November; and seldom reach any part of the western coast of Scotland before December: there they continue in plenty until the middle of March, or perhaps later, according to the mildness or rigour of the season. In the early part of it they continue arriving in succession for a month, and in every county in Scotland, where they are found, they fly regularly from east to west.

In the same manner as woodcocks quit us, they retire from France, Germany, and Italy, making the northern and cold situations, their universal summer residence. They visit Burgundy the latter end of October, but continue there only four or five weeks; it being a dry country, they are forced away for want of sustenance by the first frost. In the winter they are found in great plenty as far south as Smyrna and Aleppo; during the same season, they are met with in Barbary, where they are called the *ass of the partridge*. We are also told that some have appeared as far south as Egypt. On the other side, they are found in Japan.

In the winter season, woodcocks abound in the neighbourhood of Athens, descending, after snow on the mountains, into the plains, and as suddenly retiring, if the weather be severe; they enter the gardens of the town in great distress rather than cross the sea, and are sometimes taken up with the hand.

In 1798, a woodcock was seen in India; it was shot at Chittagong, by a gentleman resident at Ducca. The existence of the woodcock in the East Indies had been much doubted; it was therefore exposed for the satisfaction of the curious, and was then sent to Bengal for the purpose of preservation. The author of the "Wild Sports of the East" observes, "Woodcocks are so extremely scarce, that most of the best and oldest sportsmen doubt whether one is to be found in India. However, two or three have to my knowledge been shot. Indeed, I am greatly mistaken, if I did not one day, see se-

veral brace, as I was following the course of a small spring, through an extensive jungle of underwood, near Hazary Bang. They flitted before me for about a mile, suddenly dropping as they got out of my reach, and taking great care to dodge in such a manner through the bushes as to destroy every possibility of taking an effectual aim. It was in the month of January, when we had as sharp a frost as ever I can remember to have experienced in India."

Mr. Travers of Cornwall observes, that when at a great distance from land, where the feathered tribes are rarely seen, a bird was perceived hovering over the ship: when first discovered, it was high in the air, but gradually descended, and, after making several circuits, at length alighted on the deck, and suffered itself to be taken up by the hand—it was a woodcock.

In 1799, a couple of woodcocks, in a gale of wind, alighted upon the deck of the *Glory*, man of war, as she was cruising in the channel.

Woodcocks, like other birds, are attracted in their flight, by the glare of light; and many instances have occurred, at the Eddystone, Cromer, and Bidstone, lighthouses, of their being killed by flying against them in the night. In 1796, in the lighthouse, upon the Hill of Howth, as the man who attended was trimming his lamp, he was surprised by a violent stroke against the outside of the windows, which broke a pane of plate glass cast for the place, and more than three eighths of an inch thick. On examining the balcony, which surrounds the light, he found a woodcock, which had flown with such violence against the pane of glass, as to break his bill, head, breast bone, and both wings. The same person had often found birds which had killed themselves by flying against the windows, but never before knew the glass to be injured.

In February, 1798, a woodcock was caught in Clenston Wood, by the gamekeeper, in the rabbit nets, and preserved alive: a brass ring was put on its left leg, and it was let fly from Whatcombe House. In the following season, upon the 13th of December, the same bird was shot by Mr. Pleydell, in the same wood in which it had originally been taken. A second instance occurred in February, 1802, when a woodcock was taken alive in the same wood; and, after a tin ring, with the date, was affixed round its leg, the bird was liberated. Upon the 11th of the following December the bird was shot in the same wood where it was captured the preceding February.

A white woodcock was seen three successive winters in Penrice Wood, near the Castle of that name in Glamorganshire. It was repeatedly flushed and shot at during that time, and was at last found dead, with several others, which had perished by the severity of the winter of 1793.

Consett informs us that the inhabitants of the north of Europe, to whose woods and swamps the woodcock retires in the summer, never eat these birds, regarding their flesh as unwholesome from the circumstance of its having no crop; though from other accounts, we are given to understand that the eggs of the woodcock are considered as one of the greatest dainties.

The neighbourhood of Torrington, in Devonshire, was formerly

## W O O D C O C K

remarkable for woodcocks and snipes. One person has been known to send birds of that description to London to the amount of several hundred pounds in the course of a single season.

It appears that the woodcock, though it has large prominent eyes, cannot support a glaring light, and does not see well but in the twilight. This is evinced by its manner of life, and by its motions, which are never so agile as in the dawn or at the close of the day; and so strong is this propensity to action at the morning and evening, that woodcocks confined in a room have been observed to flutter regularly at these times, while, during the day or the night, they only run on the floor without attempting to fly; and, probably, woodcocks remain still in the dark nights, but in moonlight, come abroad in quest of food. It is well known they leave their retreats on the approach of evening, and spread among the glades, always keeping the little paths, (by which means the nets are so destructive); they are then seeking the wet pasturage, ponds, or water, by the skirts of the woods, where they wash their bill and feet, which are daubed with earth in searching for worms and insects.

Though woodcocks in general leave this kingdom, yet they are occasionally known to remain and even to breed. Pennant notices this circumstance; and Mr. Latham states, that on the first of May, 1769, the gamekeeper of Horace Mann, Esq. shot a couple of woodcocks in Chellenden Wood, and also a couple the preceding day; and each of these couples had formed a nest. He likewise says that a friend of his met with a female woodcock sitting on her eggs, and the male close at hand. She was so tame, as to suffer him to touch her without rising; this was in a wood near Farningham in Kent. About the year 1781, a pair of old woodcocks, with five young ones in company, full fledged, were found.

The woodcock makes an artless nest on the ground, composed of a few dried fibres and leaves, generally against an old stump or root of a tree; the eggs, four or five in number, are larger than those of a pigeon, of a rufous grey, marked with dusky blotches; the young run as soon as they are hatched, but as they cannot immediately provide for themselves, the old birds accompany them for some time.

Woodcocks have bred occasionally in various parts of England; but whether this arose from the old birds being wounded and unable to accompany their fellows when they quit this country in the spring, or otherwise, will perhaps never be satisfactorily ascertained. Young woodcocks have been found in the High Woods near Colchester; and in the year 1801, a gentleman shooting in a wood of Mr. Wenive, of Brettenham, in Suffolk, flushed a woodcock, which he shot at and missed; the bird returned again to the spot; and a nest, with three eggs, was discovered: the nest was carefully watched, and two days after the eggs were hatched, and the young safely taken off by the old ones. A young woodcock was found the same year in Bewdley Park, Warwickshire; and also a nest, with three young woodcocks, a few miles beyond Dartford in Kent. In Birchwood, near Sharford House, in Hampshire, a woodcock's nest was found with

four eggs which were hatched, notwithstanding the visits of the curious frequently disturbed the parent bird.

The Duke of Gordon's gamekeeper, on the 15th November, 1797, shot a woodcock, the quill feathers of which were perfectly white; their coverts both greater and lesser, upon the upper side of the wing, of the same colour; on the lower side the coverts were also white, except the three outermost feathers, which, together with those upon the rest of its body, were of the usual colour.

In March, 1798, the gamekeeper of Sir John Lade, shot a woodcock completely white, in a wood in the parish of Selehurst, in Sussex; and in November of the same year, Mr. Goodyear, of Box, Somersetshire, killed one with white wings.

In November, 1801, Mr. Powell, of Okeover, Hall, Derbyshire, killed a woodcock, whose plumage was a bright chesnut, faintly mottled, except the neck and breast, which, as well as the legs and feet, were nearly white. The wing feathers were beautifully mottled with chesnut, upon a fawn-coloured ground. The head and eyes were larger than usual, the bill thicker, and of a fine brown colour. Many other instances of the seeming sport of nature in this bird might be enumerated.

**WOODCOCK SHOOTING.** See the article SHOOTING.

**WOODPECKER.** A chesnut horse, foaled in 1773, the property of Sir Charles Danvers, Bart. and sold to the Honourable Richard Vernon, of Newmarket.

Woodpecker was got by King Herod, out of Miss Ramsden.

At Newmarket first spring meeting, 1777, Woodpecker won a sweepstakes of 200gs each, (12 subscribers) 8st. 7lb; D. C. beating Lord Grosvenor's grey colt, by Twigg, out of Sod's dam: 3 to 1 on Woodpecker. In the second spring meeting, at 8st. 10lb. he received 125gs. compromise from Lord Rockingham's brother to Solon. At Ipswich, June 30, he won the king's purse of 100gs for four-year olds, 9st.; beating Sir J. Pennyman's North Pole, Lord Clermont's Hydaspes, and Lord March's Skirmish:—Even betting on Woodpecker. At Newmarket July meeting, at 8st. 7lb. he beat Lord Clermont's Hydaspes, 8st. 2lb. across the flat, 100gs:—2 to 1 on Woodpecker.

At Newmarket Craven meeting, 1778, Woodpecker won the Craven stakes of 5gs. each, for three-year olds, 8st; four-years, 8st. 9lb; five-yrs, 9st. 1lb; six-years, 9st. 5lb.; and aged, 9st. 7lb.; from the Ditch to the turn of the lands, beating Mr. Pratt's Maiden, aged; Mr. Price's Risque, 4 years old; Duke of Grafton's Skipjack, 3 years old; Mr. Parker's Buskin, four-years old; Lord Grosvenor's Laurel, six-

years old; and 23 others which were not placed; amongst whom were Mr. Shafto's Tilbury, 3 years old; Mr. Vernon's Warwick, 4 years old; Lord Clermont's Passenger, 4 years old; Lord Milsingtoun's Pink, 4 years old; Duke of Bolton's Troilus, 4 years old; Mr. Lechmere's Tremamondo, 4 years old; Mr. Gregory's Lais, 3 years old; Lord E. Bentinck's Clan Vengeance, 3 years old; Mr. Calley's Puffendorf, 3 years old; Mr. Compton's Wafer, aged; Sir H. Fetherston's Proserpine, aged; Mr. Cartaret's Jonathan, 5 years old; Mr. Smallman's Toothdrawer, 3 years old; Lord Ossory's Tuscan, 3 years old; Mr. Jennings' Dolly, 3 years old; Mr. Brand's Caprice, 4 years old; Lord Clermont's Masquerade, 6 years old.—7 to 2 against Woodpecker, 6 to 1 against Maiden, 8 to 1 against Laurel, 9 to 1 against Masquerade, and 12 to 1 against Risque. On Monday in the first spring meeting, at 8st 5lb. he received forfeit from Lord Clermont's Mistle, 4 years old, 8st. 4lb.; and Sir C. Bunbury's Comedy, 3 years old, 7st; R. C. 200gs. each, h. ft. And on Friday, he won 50l. for horses, &c. rising 5 years old, 8st. 7lb. R. C. beating Lord Abingdon's Hurlothrumbo, Lord Foley's Commissioner, and Sir J. Moore's Houghton:—5 to 2 on Woodpecker. In the second spring meeting, he won 50l. for 4 year olds, 7st. 5lb. and 5 years, 8st. 6lb; D. C. beating Lord Abingdon's Magna Charta, 4 years old;

Mr. Stapleton's Cannibal, 5 years old; Lord Clermont's Dragon, 4 years old; and Mr. Brand's Lumbago, 4 years old:—2 to 1 on Woodpecker, and 3 to 1 against Cannibal. The above were his only engagements that year.

At Newmarket Craven meeting, 1779, Woodpecker won the Craven stakes of 10gs. each, for three-year olds, 8st; four-years, 8st. 9lb.; five-years, 9st. 1lb.; six-years, 9st. 5lb.; and aged, 9st. 7lb.; from the Ditch to the turn of the lands, beating Duke of Grafton's Stormer, 4 years old; Mr. Pigott's Humbug, 5 years old; Mr. Walker's Leapfrog, 3 years old; Mr. J. Pratt's Surprise, 5 years old; Mr. Shafto's Cordial, 3 years old; Sir J. Moore's Hero, 3 years old; Lord Grosvenor's Mambrino, aged, (fell lame); Lord Derby's Harlequin, aged; Mr. Vernon's Alert, 3 years old; Lord Clermont's Cytherea, 3 years old; Mr. O'Kelly's Toothdrawer, 4 years old; Mr. Tattersall's Hammer, 3 years old; Duke of Bolton's Hang-him, 4 years old, and two others:—Even betting on Woodpecker, 3 to 1 against Mambrino, and 5 to 2 that one of them won. On Monday, in the second spring meeting, at 8st. 7lb. he beat the Duke of Bolton's Cow, 5 years old, 7st. 8lb. the two middle miles of B. C. 100gs.:—2 to 1 on Woodpecker.

At Newmarket first spring meeting, 1780, Woodpecker, 8st. 1lb. won a sweepstakes of 200gs. each, h. ft. B. C. (eight subscribers) beating Mr. Douglas's Bourdeaux, 5 years old, 7st. 12lb.; Lord Grosvenor's Pot80's, 6 years old, 7st. 13lb.; Lord Derby's Laburnum, 5 years old, 7st. 9lb.; and Lord Ossory's Dorimant, aged, 8st. 4lb.—6 to 5 on Pot80's, 9 to 2 against Woodpecker, 9 to 2 against Bordeaux, 10 to 1 against Laburnum, and 10 to 1 against Dorimant. After being beat by Truth, in the Houghton meeting, he was sold to Mr. Vernon.

At Newmarket Craven meeting, 1781, Woodpecker won the Craven stakes of 10gs each, for 2 year olds, 6st. 3lb.; 3 years, 8st.; 4 years, 8st. 9lb; 5 years, 9st. 1lb.; 6 years, 9st. 5lb.; and aged, 9st. 7lb; from the Ditch to the turn of the lands, beating Captain Bertie's Flying Gib, 4 years old; Lord Grosvenor's Whipcord, 4 years; General Smith's Girandola, 4 years; Mr. Parker's Boringdon, 4 years; Lord Derby's Fame, 5 years; Mr. Kingsman's Agricola, 2 years; Sir J. Lade's Knight-Errant, 6 years; Mr. O'Kelly's King Fergus, 5 years; Lord Clermont's Masquerade, aged; Mr. Golding's Smart,

2 years; Duke of Bolton's Greybeard, 5 years; Mr. Sulsh's bay filly, by King Herod, out of a Sister to Pacolet, 2 years; Duke of Grafton's Pandora, 4 years; Mr. Vernon's Torrent, 4 years; and Mr. Stapleton's Magog, aged, who broke down in running:—3 to 1 on Woodpecker, 4 to 1 against Girandola, and 4 to 1 against Fame. In the second October meeting, he walked over B. C. for the Clermont cup. On Monday in the first October meeting, at 8st. 7lb. he won 50l. for horses, &c.; R. C. beating Sir J. Shelley's Clandon, 5 years old, 8st.; and Duke of Grafton's Boxer, 5 years, 8st:—3 to 1 on Woodpecker. On Saturday, at 8st. 10½lb. he beat Mr. Fox's Spitfire, 4 years old, 7st. 8½lb. R. M. 200gs:—6 to 4 on Woodpecker. On Wednesday, in the second October meeting, he won 140gs. 8st. 7lb. each, B. C. beating Lord Grosvenor's Pot80's, aged:—7 to 4 on Woodpecker. And on Friday, at 9st. 2lb. he won a subscription of 5gs. each, (13 subscribers) for horses, &c. B. C. beating Lord Clermont's Hollandoise, 6 years old, 8st. 13lb; and Duke of Grafton's Boxer, 5 years, 8st. 6lb:—5 to 4 on Woodpecker. This was the last time of his running.

Woodpecker was beat seven times, viz. once by Fleacatcher; once by Dorimant; once by Fieri-Facias, to whom he allowed, 3st. 7lb.; once by Bourdeaux, once by Truth; and twice by Pot80's. He paid four forfeits, viz. in the Grosvenor's stakes, won by Prince; once each to Dictator, Guildford, and Mr. Pigott's Nutcracker.

Woodpecker was a stallion at Rushbrook, near Bury St. Edmund's, Suffolk.—In 1782, at 3gs. and 5gs.; in 1783, 1784, and 1785, at 3gs. and 10s. 6d.; in 1786, at Petworth, Sussex, at 10gs. and 5s.; in 1787, at Rushbrook, at 10gs. and 10s. 6d.; in 1788, at Petworth, at 10gs. and 10s. 6d.; in 1789, and 1790, he was not advertised; in 1791, at 20gs. and one guinea; in 1792, at 30gs. and 1 guinea; in 1793, at 20gs. and one guinea; and afterwards at 12gs. and one guinea.

Woodpecker died in the Earl of Egremont's stud, at Petworth, Sussex, the latter end of the year 1798, aged 25.

**WORMING DOGS.** It would perhaps be difficult to discover the inventor of this ridiculous operation. It will not have the effect erroneously attributed to it, namely of rendering the animal incapable of biting when labouring under paroxysms of hydrophobia. How could it ever be supposed that extracting a sinew

which runs longitudinally under a dog's tongue, would have the above effect, is a matter of surprise!—it is a foolish idea, the offspring of ignorance: it is putting a generous animal to pain, where no possible benefit could be reasonably expected.

**WORMS.** According to the veterinary notions of the present day, worms are, generally speaking, not considered as injurious to the health of the horse. In order to place this interesting subject in as clear a view as possible, I shall have recourse, in the first place, to the lucid and scientific Lectures of Mr. Percival, which embrace also the ideas of Mr. Bracey Clark on the same subject, and afterwards give the notions of preceding writers, as the matter is, after all, but very imperfectly understood.

Worms (says the eloquent Percival) by presumptuous dabblers in veterinary practice, have ever been, and are still, regarded as destructive vermin, a notion to which we may refer those vulgar prejudices of the present day that associate an utter dread and abhorrence with the idea of worms *crawling alive* within an animal's bowels; which prejudices have in no few fatal cases been made the ready instruments of the consciously ignorant farrier in repressing the inquisitiveness of his employers, and putting an end to all further inquiry after the cause of his unfortunate patient's death.

Four kinds of worms have been seen within the bowels of horses: viz. the *ætrus*, or bot; the *lumbricus teres*, or long white worm; the *ascaris*, or small thread-like worm; and the *tænia*, or tape worm.

**Bots.**—The bot, an animal whose *nidus*, or natural habitation, appears to be the stomach, is so well known in its general characters to every one who possesses any acquaintance with horses, that I do not conceive a description of it in this place at all necessary.—Its natural history is interesting. Mr. Bracey Clarke has exposed the erroneous view that was formerly taken of the bot in regarding it as a worm; he has demonstrated that it is the *larva*, or caterpillar, of a particular species of the genus *æstrus*, or gad-fly. He has particularized three species of bots; which, however, are rather distinguished from one another by incidents connected with their natural history, than by any specific corporal characters. The first is the *æstrus equi*, or large spotted horse bot; the second is the *æstrus hemorrhoidalis*, or fundament bot; the third Mr. Clarke has named the *æstrus veterinus*, or red bot.

Speaking of *æstrus equi*, Mr. C. says, “as it is necessary to break into the circle of its history at some point, I shall begin with an account of the egg, and its deposition upon the skin of the legs of the horse, which is done in the following remarkable manner:—when the female has been impregnated and the egg sufficiently matured, she seeks among the horses a subject for her purpose, and, approaching him on the wing, she carries her body nearly upright in the air, and her tail, which is lengthened for the purpose, curved inwards and upwards: in this way she approaches the part where she designs to deposit the egg; and, suspending herself for a few seconds before it, suddenly darts upon it, and leaves the egg adhering to the hair: she hardly appears to settle, but merely touches the hair with the egg held out on the projected part of the abdomen. The egg is made to adhere by means of a glutinous liquor secreted with it. She then leaves the horse at a small distance, and prepares a second egg, and, poising herself before the part, deposits it in the same way. The liquor dries, and the egg becomes firmly glued to the hair: this is repeated by these flies till four or 500 eggs are sometimes placed on a horse.” The parts chosen for the deposition of these eggs are those liable to be licked by the tongue; the inside of the knee is a favourite spot, and next to this the side and back part of the shoulder, and less frequently the extreme ends of the hair of the mane. The common notion is, that the ova are licked off the skin, and thence carried into the stomach; but Mr. C. observes—“I do not find this to be the case, or at least only by accident; for when they have remained on the hair four or five days, they become ripe, after which time the slightest application of moisture and warmth is sufficient to bring forth in an instant, the latent larva. At this time, if the tongue of the horse touches the eggs its *operculum* is thrown open, and a small active worm is produced, which readily adheres to the moist surface of the tongue, and is from thence conveyed with the food to the stomach.” And it appears that the irritations of the common flies is the instigation of the animal's licking himself; not, however, that this is absolutely necessary, for “a horse that has no ova deposited upon him may yet have bots, by performing the friendly office of licking another horse that has.” The larva or worm being hatched and lodged in the stomach, immediately clings, by means of its *tenticula*—(two dark brown hooks, between which is

its mouth) to the cuticular coat, which they pierce, though they never insinuate their points into the muscular or sensitive tunic beyond it; in this manner, so pertinaciously does the bot adhere, that in our attempts to unhitch it, it will frequently suffer its hooks to be broken, or even its body severed, rather than quit its hold. Now and then, but I believe very rarely, they are found hooked in the villous coat; these, however, are nothing more than stragglers, bots probably that had on their arrival in the stomach, been hastily carried with the aliment into its vascular part, before they had the power of fixing their hooks in the cuticular. Here then is a fact which ought to stifle our apprehensions about the pain and irritation that these animals are said to occasion: how they can cause either when they are fastened to an insensible part, to a part as devoid of feeling in itself as the very hoofs are, I have yet to learn. The bot, thus transported about the latter part of the summer, while horses are at grass, remains in the stomach through the winter, until the end of the ensuing spring, when, being at the consummation of this stage or form of existence, it spontaneously disengages itself, and passes with the chymous matter into the intestinal canal; where its stay probably is but short, since it now lies loose amongst the alimentary matters, and is eventually cast out from its animal abode with the dung. Now, it has long been a question, and one which is not yet set at rest, on what these worms subsist in the stomach. Mr. Clark supposes their food to be chyme, which (he says) being *nearly pure aliment*, affords probably but little excrementitious residue. I do not, however, believe that to be nearly pure aliment—what we understand by chyle, is not found in the stomach, much less in the cuticular part of it, where, as far as I have observed, the food itself remains unchanged even into chyme. For myself, I feel inclined to think that the mucus, an abundance of which is deposited upon the surface of the alimentary mass, to sheath the stomach from mechanical irritation, constitutes their food, which probably possesses little or no excrementitious matter, since it is itself re-absorbed in many parts of the body; and what favours this opinion is, that there are bots in the sinuses of the head, in the skin, &c. of cattle, which can have no other sustenance than the secretions of those parts; and that worms in the intestines of animals are nourished in this way, is rendered highly probable by the existence of the ascaris

in the colon and rectum guts, that contain little or nothing else but what is innutritious.

It is about the month of June or July, that the bots, having left the gastric region and been transported with the aliment through the windings of the intestinal tube, are discharged with the fæces; and at this period it is, that people discern that their horses (particularly those which have been at grass the preceding autumn) have worms; to get rid of which, vermifuges come all at once into general requisition; but if these well meaning people would only have a little patience, these imaginary plagues would soon quit the bowels of their horses of their own accord. The larva being ejected, lies not long exposed upon the ground, or concealed in the dung, but quickly dries up, and shrinks into the state of *chrysalis* or grub, in which torpid condition it continues for a few weeks; at the expiration of this time, the superfluous moisture being removed, and the parts of the future insect being hardened by drying, it bursts from its confinement, and the fly appears making its exit at the small end. On quitting their shell, they, in a few hours, take wing and then seek their mates.

The *fundament bot*, or *æstrus hemorrhoidalis*, chooses the lip of the horse for depositing its eggs, which is very distressing to the animal from the excessive titillation it occasions; for he immediately after rubs his mouth against the ground, his fore legs, or sometimes against a tree, with great emotion; till the animal at length, finding this mode of defence insufficient, enraged quits the spot, and endeavours to avoid it by galloping away to a distant part of the field; and if the fly, still continues to follow and tease him, his last resource is in the water, where the *æstrus* is never observed to pursue him. The larva or grub of this species inhabits the stomach as the former, generally adhering to the white lining, and is disposed promiscuously in dense clusters after the same manner; they may, however, be distinguished from them by being in general smaller, longer in proportion to the bulk and rounder. These bots quit their habitation in the same season of the year, but are rendered remarkable by their sticking more or less within the verge or opening of the anus, adhering to its soft lining, and producing considerable irritation. Its change to the chrysalis state, and further transformation into that of insects, which happens in about two months, are similar to what befalls the *æstrus equi*.

Of the *æstrus veterinus*, or *red bot*, so designated by Mr. Clark, in preference to retaining the epithet *nasalis*, which conveys a false notion of its habitation, the same historical detail does not appear to be made out. The mode of this insect depositing its eggs or nits is at present unknown. They perhaps deposit them about the lips or legs, like the former species. The larva of this species is also not certainly known. That it inhabits the stomach, in the same manner as the two former species, there can be little doubt.

Mr. Clark is decidedly of opinion that bots are no way injurious to the horse; though he makes some observations on the most effectual mode of destroying them. At the natural period of their transformation (says he) they come away readily enough of themselves; and if it happens at the time that any medicine has been administered, it is considered as proof sufficient of its efficacy, and mistaken for the consequences of it:—so easy is it to draw wrong conclusions. Neither opium nor tobacco, given for several days, have any effect upon them. We can, it is true, force the poison down the horse's throat, but we cannot afterwards get it into the throat of the worm, who is placed in his own element, and can refuse the food that does not suit him. The wisest measure for securing horses from their effects is to prevent their propagation or access, and their habits afford us an effectual mode of doing this. The eggs of the *æstrus equi*, which are very conspicuous on the knee, the mane, and the sides of the horse, may be washed off by a brush and warm water, or still more effectually removed by a pair of scissors. The same may be done for the *hemorrhoidalis*, they may be thus removed from the lips and beard.

The other species being smaller, more rare, and probably less troublesome, require therefore less our consideration.

In respect to the *hemorrhoidalis* also, where horses have been much out at grass the preceding year, they should, occasionally, in the warm months of the next summer, be examined for them, when they will be found, as already stated, hanging to the extremity of the rectum, and should be removed by the fingers. The destruction of a single one at this season of the year, is not only the death of an individual and its effects, but the almost certain destruction of a numerous progeny; it is also useful in preventing the irritation

which the spines of the bot occasion in the anus, which irritation becomes very distressing to the animal if he is used on the road, occasions him to move awkwardly, wriggle himself about, and to be sluggish; and, though beaten severely, he soon relapses into his awkward manner of going; which, as this happens generally in warm weather, is most commonly attributed to mere laziness.

It has been conjectured that bots might prove serviceable to the animal by aiding the cuticular coat in the trituration of food; but I do not think that any proof or incontrovertible argument has been adduced in support of such a power being possessed by the stomach of the horse.

That nature should have created an animal, and designed it as an inhabitant of the stomach of another animal, without some good, (though quite unknown) is, I think, highly improbable and irreconcilable with other beautiful and more readily-explained operations. Taking it for granted that bots do good rather than hurt, surely we need not be solicitous about removing them; for, though we cannot demonstrate their beneficial influence, we can, from all the circumstances we have a knowledge of regarding them, boldly assert "*that they are in nowise injurious.*" Yet we cannot persuade the world to entertain the same opinion.

"In all works on Farriery (Mr. Percival observes) you will find some recipe extolled as a vermifuge; which, unless it contain a purgative ingredient, you may at once expunge as inefficacious; for we know of no medicine that has the power of destroying bots in the stomach; and if we did, we are not sure that, even when dead, they would be detached from its cuticular coat; though if they were in its vascular part, they would be subjected to the action of the gastric juice. No medicine, therefore, not even a purge, can operate as a vermifuge but at a certain season of the year; when, if you will but suspend its exhibition for a while, the worms will all readily pass away without your assistance. But, if we must subscribe something as a vermifuge, we have no other resource than a common purge: a dose of aloes is all that is required, though it is usual to combine it with calomel, which will certainly render it more active, and herein resides all the (supposed) specific virtue of the latter medicine as a vermifuge."

The *long white worm*, or *lumbricus teres* is now and then formed in the bowels of the horse after death; though it seldom

or never happens, unless perchance one be voided, that we have any knowledge of its existence during life. This worm is white, round, sharp pointed, several inches in length, and in form resembling the common earth worm. They inhabit the small intestines, are but seldom seen in the large guts unless medicine have been given, and never, I believe, have been detected in the stomach. Strange accounts have appeared of the injuries sustained from the presence of these worms in the bowels, but so inconclusive are they, in consequence of the remedies employed having been of a more destructive tendency than the worms themselves, that it is utterly impossible to determine what importance should be attached to them. Apprehensions have been entertained by some of their *starving the horse to death*, by a consumption of chyle: we have no more reason, however, to believe that these worms feed on chyle, than we have of the bots being nourished by chyme: on the contrary, I should argue, on nearly the same grounds, that the aliment might be the intestinal secretion.

I am not aware of any symptoms on which we can rely that indicate the presence of these worms: emaciation, inordinate appetite, symptoms of pain in the belly like those of gripes, unhealthy appearance of coat, a little exsiccated mucus appearing about the verge of the anus, are said to be signs of their existence; but I should advise him who values a correct opinion to withhold it until one or more of these worms shall have been discovered in the dung: and it commonly happens that a solitary one, of considerable length, makes its appearance.

Should any be observed in the fæces, we may, with a view of expelling others, administer an aloetic purge, either with or without calomel; though it is by no means certain that this will have the desired effect.

*The Ascaris.*—The ascarides, formed in the bowels of the horse, are small needle-like worms, in shape very much resembling those of the same name that infest the human intestines; they are longer, however, and of a dark colour, approaching to black. In the large guts, mostly in the cœcum, they are now and then discovered in prodigious quantities, to which the farrier does not fail confidently to assign the cause of the horse's death. Those however who have carefully inspected such bowels after death, have, I believe, but in very few instances met

with any erosion or injury that could be attributed to these worms. We can with little more certainty venture an opinion on their presence than we can on that of the *lumbrici*, or long white worms, unless we observe some of them in the dung; though they may and do sometimes occasion so much irritation about the rectum, that the animal, from experienciug a troublesome *tenesmus*, ejects a little mucous secretion, from time to time, which, adhering to the anus, and becoming exsiccated, is converted into a whitish powder.

Should any symptoms of pain or irritation make their appearance, which there is reason to believe arose from the existence of worms, I would administer a full dose of aloes, or of aloes conjoined with calomel; or, if this failed to cause their expulsion in great numbers, I would have recourse to oil of turpentine, in large doses, in the form of enema, (clyster) and follow up its exhibition with either of the purges just mentioned. In general, about a week should elapse between the administration of each dose of the purgative medicine; for it will be necessary, in most cases, to repeat it once, if not twice.

The *tænia*, or tape worm has been seen in the intestines of the horse. One case only, in which *tæniæ* were found after death, is recorded in the *Sick Journals* of the Royal Horse Infirmary. Professor Peall makes this remark on it:—"The tape worm is, in fact, so very rarely seen, that, but from the circumstances of the possibility of its being met with, it would scarcely deserve to be noticed as an enemy to the horse."

"There is nothing (says Mr. Denny) so destructive to the health and appearance of a horse as worms. When they have obtained a settlement in the intestines, neither the labour of the groom, nor the liberality of the master, will prove of any avail towards improving the animal's condition; for, as fast as the chyle is formed from the aliment, which ought to be converted into blood, these numerous guests first satiate their craving appetites, and leave but a scanty supply for the exhausted system of the horse: so that a double allowance of corn would not preserve a healthy state; because the digestive organs cannot exert an extraordinary power for any length of time, without producing such a state of debility as to render them incapable of performing, afterwards, their proper office.

The most common kinds are the following: *bots*, which many young horses

are subject to in the spring: those that resemble earth worms, and which, by physicians, are called *terets*, or *rotundi*: those that are about the size of the largest sewing-needles, with flat heads, called *ascarides*: that species of worm called *tænia*, or *tape-worm*. Whatever variety be observable in these different kinds, except the last, it consists chiefly in the difference of their size and colour, which are only accidental. We shall speak of these in their order.

*Bots*, that are found in the stomachs of horses, and are sometimes the cause of convulsions, appear to be of the same kind with those in the rectum, being only somewhat larger and of a deeper red colour. They are exactly the same in shape and figure, both having little sharp prickly feet along the sides of their bellies, like the feet of hog-lice, which seem to be of use to fasten them more securely to the part where they are found, and from whence they draw their nourishment till they come to maturity.

The *teretes* are of the same kind with those we often see voided by children. They resemble common earth worms in many respects, only that they are sharper at both ends, are more callous towards the middle, and do not so easily contract or dilate themselves. In children, and in grown persons too, they seldom exceed six inches in length; but Gibson says, he has known them to be passed by horses of a size larger than a man's finger, and about eighteen inches long, and some of them, when slit open, full of eggs. These, notwithstanding, are seldom hurtful to horses, further than as they hinder them from thriving.

The small worms like needles resemble those of the human body called *ascarides*; some of them are white, and some of an azure colour, with flattish heads. These are very troublesome and hard to be expelled, and they expose horses, more than any of the other kinds, to gripes, and other uneasy affections of the intestines.

As to the cause of worms in horses, it is imagined that, as in the human subject, some constitutions are more inclinable to breed worms than others. Gibson says, the most usual cause of worms is foul or high feeding, which occasion crudities and slimy indigested matter in the stomach and bowels (especially in horses that have been pampered for sale) forming a proper nidus for worms. This, indeed, may be the case, but the primary

cause of worms is that which occasions these crudities, to wit, a want of energy in the functions of the stomach and bowels, as worms are never found in animals perfectly healthy in these respects.

“The signs of worms in horses (says Gibson) are various, according to their different kinds. The bots that many horses are troubled with in the beginning of summer, are always found sticking to the rectum, and are often thrust out with the dung, along with a yellowish coloured matter like melted sulphur. They are no way dangerous there, but they are apt to make a horse restless and uneasy, and rub his breech against the posts. The season of their coming is usually in the months of May and June, after which they are seldom to be seen, and rarely continue in any horse above a fortnight or three weeks. Those that take possession of the membranous portion of the stomach, are extremely dangerous in causing convulsions, and are seldom discovered by any previous signs, before they bring a horse into violent agonies.”

The *teretes* or earth-worms give little disturbance to a horse, and would hardly be discovered, unless they were seen now and then to come away with the dung. Frequently, horses void one or two, and no more; and sometimes they will void pretty large quantities of the young brood, not much larger than the *ascarides*, only of a red colour, and not white, as the latter generally are. They are most usual in autumn, or the beginning of winter, though a horse shall now and then void one or two of these at other times of the year.

The *ascarides*, or small needle-like worms, are very troublesome to horses, breed at all times of the year, and often when one breed is destroyed another succeeds. These are not at all dangerous; yet when a horse is pestered in this sort of way, though he will go through his business tolerably well, and sometimes feed heartily, yet he always looks lean and jaded; his hair stares as if he was sickly, and nothing that he eats makes him thrive. That he feels pain too is plain, for he often strikes his hind feet against his belly, which shews where his grievance lies, and is sometimes griped, but yet without the very violent symptoms that attend a colic or strangury. He never rolls or tumbles, but only shews uneasiness, and generally lays himself down quietly on his belly for a little while, and then gets up and begins to feed;

but the surest sign is, when a horse voids these worms with his dung.

With regard to the cure, if a horse be troubled with bots, Gibson says, he may be relieved without much expense or trouble, only by giving him a spoonful of savin, cut very small, once or twice every day, in oats or bran moistened; and if three or four cloves of chopped garlick be mixed with the savin, it will do better, for garlick is of great service in these complaints. Horses that are troubled with bots, ought to be purged with calomel and aloetic purges before the weather grows too hot; and if they be kept to a clean diet after this, it will be a great chance if ever they are troubled with them any more. As the bots generally happen about the grass season, those horses that are turned out to grass often get rid of them there, by the first fortnight's purging; and therefore those that have the convenience of a good pasture for their horses, need not be very solicitous about giving them medicines.

The earth-worms, which some writers call *teretes*, *rotundi*, or *lumbrici*, are also best conquered by calomel and occasional aloetic purges, for worms often come away in purging, when, till then, it has not been known that the horse was troubled with them; and it has been observed, after these have been voided, that the animal has thriven better, grown more lively, and shewn more alertness at his business. There can scarcely be a better plan than is supplied in the following formulæ recommended by Mr. Denny:

Take of Calomel, one drachm;  
Aniseeds, in powder, half an ounce;  
Treacle, enough to make a ball.

This is to be given in the evening; and the next morning the following is to be administered:

Take of Succotrine aloes, in powder, one ounce;  
Ginger, in powder, two drs.;  
Treacle, enough to make a ball.

The foregoing bolus and purgative ball must be repeated, within an interval of nine days, until the horse has taken three doses. Then we are advised to give the following alterative powder, daily, for about a month. This process does not require any change of diet, or involve any hazard from the effects of cold:

Take of Ethiop's mineral,  
Crude antimony, prepared,

Aniseeds, in powder, half an ounce.

Mix them.

The treatment of the horse during this course of worm medicines, is that in common cases of physic.

Some prefer giving Barbadoes aloes for the removal of worms, thinking it the more efficacious, because its operation is very rough. Gibson says, it may be given to hackneys and other horses of small value; but he never found it more efficacious than the succotrine, at the same time that it exposes a horse more to gripes and other dangerous disorders, unless it be properly managed. The following he gives as a cheap purge of this kind, and well corrected:

Take of Barbadoes aloes, one ounce;  
Salt of tartar, two drachms;  
Ginger, grated, a drachm and a half;  
Oil of amber, a middling spoonful;  
Syrup of buckthorn, sufficient to make a ball.

To this we see no objection, except as to the quantity of aloes, which would be too considerable even of a milder sort. Yet most of the common farriers do nothing more than work an ounce of the coarsest aloes into a ball before a warm fire, and when they have dipped it in oil, give it without any other preparation. But this sort of treatment is unfit for any horse that we set a value upon.

The kind of worms called *ascarides* sometimes come away from a horse in great numbers with the help of a purge, and some get quite clear of them with purges only. But this does not very often happen, for the horses that breed *ascarides*, above all others, are subject to slime and foulness in their intestines. In the human body, *ascarides* are thought to be bred in the rectum, near the fundament, but in horses, no other kind than bots usually adhere to that gut. On the contrary, these worms in them seem to be lodged about the beginning of the small intestines near the stomach, where they feed on the alimentary parts of the chyle. The bots, in a horse, are often seen sticking near the sphincter ani, and are continually dropping away with the dung. But the *ascarides* are seldom seen there, except when the animal has had a purge given him, or when he falls into a natural purging, which often happens from the irritation of the bowels, and then they come away in very great numbers, ac-

accompanied with much slime and mucus. Bots seldom alter a horse's looks, but these not only make a horse grow lean and look emaciated, but on opening his mouth one may perceive a more than ordinary languid whiteness, and a sickly smell, instead of that liveliness of colour that is always perceivable in the mouth of a sound and vigorous horse. So that, whatever be the primary cause, these worms seem in a great measure to proceed from a vitiated appetite and a weak digestion, which renders them the more difficult to be removed; for which purpose, recourse must be first had to the foregoing remedies, and after them, such medicines as are proper to strengthen the stomach, promote digestion, and give tone to the solids.

Gibson's treatment of a horse that is subject to these worms is the following:

Take of Calomel, prepared, two drs.;

Diapente, half an ounce;

Make these into a ball, with a sufficient quantity of conserve of roses, and give it in the morning, keeping the horse from meat an hour or two before and after the dose.

The next morning, administer a moderate aloetic purge, taking great care to keep the horse from wet, or from any thing that may expose him to take cold. The above calomel ball, and the purge, may be repeated in six or eight days; and again in six or eight days more. Or the following mercurial purge may be given, which will be less troublesome and no less efficacious:

Take of Crude quicksilver, two drs.;

Venice turpentine, half an oz.

Rub the quicksilver with the turpentine in a mortar till no particle of the former appear; then add,

Oil of savin, thirty or forty drops;

Succotrine aloes, in powder, half an ounce;

Ginger, grated, one drachm;

Syrup of buckthorn, enough to make it up into a ball.

Let one of these mercurial purges be given in the foregoing manner, viz. one in six or eight days, with all the same precautions. It will work mildly, and with little or no griping or sickness.

Another mercurial purge, which Gibson says is proper to destroy worms and to cleanse the first passages, is the following:

Take of Diagridium,

Calx of antimony,

Calomel, of each two drachms;

Succotrine aloes, six drachms;

Oil of savin, cloves, or aniseeds, thirty or forty drops.

Syrup of buckthorn, enough to form the ball.

To be given as the preceding.

When a horse has gone through a course of these mercurial purges, the author advises the following drink to be given two or three times a-week, or till the horse begins to thrive and look healthy:

Take of Rue,

Chamomile flowers,

Horehound, of each a handful;

Galangals, bruised in a mortar, three drachms;

Liquorice root, sliced, an oz.

Boil these in a quart or three pints of forge-water fifteen or sixteen minutes, in a covered vessel, and keep it covered till cold, then strain it through a piece of coarse canvas, and give it in the morning upon an empty stomach.

"Some (says Gibson) have a great opinion of *powder of tin* as an infallible cure for worms. But it is very troublesome to make, and perhaps not so infallible as some have imagined. Tin is prepared by melting down any quantity of it in a crucible, pouring it hot into a wooden bowl, and rolling it round till part of it is turned to a greyish powder. Then melting down the remaining part, and rolling it again, continuing this operation till all that can be reduced to powder is obtained from it. This may be given to half an ounce or six drachms."

We should rather advise a dose of three or four ounces; half an ounce to an ounce being commonly given to children.

Most of the preparations of antimony (continues the author) are efficacious for destroying worms: sulphur is also good in all such cases; and even crude antimony in fine powder, given with equal parts of sulphur, often succeeds, viz. an ounce in the morning and another at night: liver of antimony, *crocus metallorum*, or *stibium*, has also the same effect. Ethiop's mineral, or the *mercurius alcalisatus*, viz. two drachms of the latter, or half an ounce of the former, made into a ball, with conserve of roses, or incorporated with a sufficient quantity of any cordial ball, and given twice or three times a-week, for a fortnight, is of great efficacy. Powders made of cinnabar of

antimony, with gum guaiacum, as in the farcy, will effectually destroy worms after purging and other necessary evacuations, and be no hindrance to a horse's business. But if a horse be of a weakly constitution, and a bad feeder, we would above all things recommend the last-mentioned bitter draught to be also exhibited, which will promote a good appetite and help his digestion. When worms seem to have been bred by high feeding, want of air and due exercise, or from unwholesome food, they may be often removed by a contrary regimen, without any medicines, or at least with the help of a very few; sometimes with rue and garlick, savin, tansy, and other vegetable remedies. But when worms are the consequence of weak bowels, or owe their production to any fault in the constitution, the cure will then be difficult and tedious, and may require an alteration or change of the whole habit of the body before that can be effected."

Before we close this article we must not fail to notice a kind of worms which are frequently fatal to the gallinaceous tribe. A curious account of these is given by Mr. Weinsenthal in the Medical and Physical Journal. The inconvenience produced by these creatures is at first but slight; however, it gradually becomes more and more oppressive, until it ultimately destroys. Very few, indeed, recover; they languish, grow dispirited, droop and die. It is found, on dissection, that these symptoms are occasioned by worms in the trachea. The author says he has seen the whole of it completely filled with these worms, and has been astonished at the animal's being capable of respiration.

No effectual remedy, it seems, is known against these destructive animals. They have indeed been drawn out of the trachea by means of a feather, stripped from near its end, which is passed into the larynx and twisted round till it engages one or two of the worms, which are extracted, but without any relief to the animal.

**WORMS IN DOGS.** See DISEASES OF DOGS.

**WOUNDS.** A wound is a solution of continuity in the soft parts of an animal body, made by a hard or sharp instrument. But it may be observed, that obtuse instruments wound, and sharp ones cut into the bones. Horses and other cattle are exposed to various accidents of this kind, and as the treatment required is as nearly as possible, that which is re-

quired in wounds of the human body, we shall draw our account of wounds from the best surgical writers.

Wounds that are superficial, when cleaned from the blood, &c. are perceptible to the sight; but when they are too deep to be seen into, it is requisite to examine them either with the finger or with a probe. Where the wound is too small for the finger, a bougie is better than a metal probe, on account of its flexibility, especially where the wound takes a winding direction. In examining a wound, we should know the attitude of the patient when he received it, the kind of weapon, how far it penetrated, how it was directed, with what force the blow was given, &c. It should also be observed, what kind of fluid discharges do or did flow from the wound. The knowledge of these, with the knowledge of the animal frame, the use, &c. of each part, enable us to judge rightly of the nature of the wound, its consequences, and method of cure.

The danger from a wound will be as the size of the vessels that are divided, and the importance of the injured part with respect to life. The nearer a wound is to a vital part, the more dangerous it is. Wounds in the joints are healed with difficulty; so are those that are situated in any part subject to constant motion, as in the lungs or belly. The attending symptoms render a wound more or less dangerous. Dividing a principal artery in a limb, endangers mortification; a principal nerve, insensibility, and an atrophy. Separation of a tendon destroys as much motion as depends on the muscle connected with it. A wound in the medulla spinalis causes death, or a mortification in the lower parts. An immoderate suppuration in a deep wound, by absorption, may cause a hectic fever, and consume the patient in a marasmus. Great loss of blood endangers a dropsy. A wound in the breast and lungs, when healed, may be the occasion of a phthisis pulmonalis; and in any other considerable organ, an ulcer may remain, and prove the source of a hectic fever, or of a consumption; but great caution is necessary in determining the prognostics of wounds, particularly those which penetrate into the breast or belly, on account of the different situation of the viscera, of which we have no means of judging accurately in brutes.

The different states of a wound are included under those of digestion, or the

discharge of matter; incarnation, or filling up with new flesh; and cicatrization, or skinning over.

As for the treatment of wounds, the following particulars should be observed. When the extraneous bodies are extracted, if it can be done prudently, the hæmorrhage suppressed, all morbid tension in the wounded part removed, and the lips of the wound, where this is required, brought properly together, the dressings may be pledgets of soft lint covered with one of tow, spread with some digestive ointment, and large enough to cover the whole; these may be secured by means of such bandages as the situation of the wound best admits of: the first dressings usually remain three or four days, or until the discharge of matter renders the separation of them easy. After the first are removed, the dressing may be repeated every twelve or twenty-four hours, according as the discharge is more or less abundant or acrid. If, after the first dressing, a warm digestive is required, add to the ung. resinæ flav. a little of the ol. terebinth. or bals. capaivi. These applications need not be warmed, except when very cold; after spreading the pledget, its surface may be just warmed by holding before the fire: each time that the surface of the wound is cleansed, it should be performed by dabbing it with soft lint, and not wiping it, lest the tender granulations should be destroyed. The surface of the wound should not be made quite dry; it is better for being left somewhat moist, for thus the digestion is less interrupted.

Most writers have observed, that the principal interruption to the healing of a wound, made with a sharp instrument, is the fungus. This, however, may be suppressed by dry tow or lint, and a proper compress upon it: or if it advance above the surface of the skin, we need only to touch its edges with some escharotic, as blue vitriol. But it sometimes happens that an obstruction to healing is the flabbiness of a wound, which is generally removed by dabbing it, at each dressing, with lime water and tincture of myrrh, or with a solution of corrosive sublimate. Thus, if an ill constitution or bad habit of the body is no impediment, wounds on the exterior parts are generally soon healed.

When the wound is filled up with flesh, powdering the surface with prepared *lapis calaminaris* will usually effect the last intention of cure, *i. e.* the *cicatrizing* of the wound.

There are many accidents which occasionally are attendant on wounds in one stage or other, such as fever, or inflammation, &c. the management of which will be learned from what is already said under the different articles in which they are noticed.

When a small artery is wounded, if it be quite divided it retracts, and the hæmorrhage is soon spontaneously restrained; if it is punctured, or partially divided, if it can conveniently be come at, it may be wholly divided, or the wound enlarged, and then the artery may be tied, if proper pressure proves ineffectual. When a large artery is punctured or divided, it must be taken up and secured with a needle and ligature.

Wounds sometimes penetrate the cavity of the breast and belly, and sometimes injure one or more of the viscera; the first are known by the probe, the latter by the discharge that issues from them; if the symptoms attending a wound that penetrates into the cavity of the breast or belly, are favourable, and there is no discharge from any of the viscera, we may conclude that the viscera are unhurt; in which case, after excluding the air that may have rushed into these cavities, we may treat them as simple wounds. If any of the viscera have protruded and are unhurt, return them with all speed; but if wounded, use the glover's suture, leaving three or four inches of the ligature out of the wound. If the protruded viscera have been exposed to the air, it may be necessary, before the return of them, to use a fomentation of warm milk and water, or some thin starch. In all these cases flannel is the best bandage, because it gives way and retreats as the breath requires.

Wounds in the principal internal blood-vessels are all deemed mortal; but blood is sometimes discharged from smaller vessels into the cavity of the breast or of the belly; if this happens in the breast, it occasions great difficulty of breathing. To discharge this blood, if the wound be in the lower part of the breast, push back the lungs with a probe, that the blood may pass out; if the wound is in the upper part of the breast, an opening must be made at the most depending part, allowing the other to close. But, until the hæmorrhage appears to have ceased, which may be judged of by the strength and equality of the pulse, and the warmth of the patient's extremities, any operation will be useless. When the opening is

made, the expulsion of the matter is assisted by the efforts of respiration. In these cases the patient must be kept still, and opium given if a cough attends. If blood is poured into the belly, there will soon be laborious breathing, anxiety, and intermitting pulse, &c. If the discharge of blood is small, the patient sometimes recovers, but, if considerable, it generally proves fatal.

When a nerve is wounded, a variety of alarming symptoms comes on in proportion to the tenderness of the part it is attached to, and the peculiar irritability of the constitution. When the pain is extreme, it sometimes is relieved only by dividing the nerve. This accident is soon discovered by the sharp ichor which distils from the part, and its excoriating the circumjacent parts. When a tendon is wounded, the same symptoms do not follow as when a nerve is injured. Swelling occurs, though not suddenly, advancing gradually with the inflammation. The most common applications to wounded nerves and tendons have been of the spirituous sort, such as the *ol. tereb.* &c. but they are productive of the worst symptoms. Instead of these, put the limb into the easiest position, keep the wounded part free from cold air, avoid spirituous and hot applications, and in their stead apply warm poultices, having first covered the wound with lint; or, instead of the poultice, cloths may be applied after dipping them in warm brandy and vinegar mixed in equal parts. Fomentations may be used before the application of the poultice, if inflammation attends, or seems to be approaching; or if the case admits of it, the part may be soaked in warm water.

Wounds in the joints, when they are inflicted with cutting instruments, or with heavy weapons falling on them, are attended with danger. Though the wound is small, its consequences are often grievous, from irritation, from the admission of the air, from the loss of synovia, &c. Much depends on the habit. From a large wound in a joint, caused by a fracture, nothing remarkable has followed; yet fatal consequences have been the result of a small one in other instances. However favourable appearances may be, a guarded prognostic should always be given. Penetrating wounds of the joints almost always are dangerous. A mere incised wound into a joint, from letting in air and injuring the ligamentous parts, has often proved fatal. The two great consequences to be avoided in wounds of

the joints are inflammation and pain; the first is to be attempted by bleeding, and pursuing the antiphlogistic plan; the latter, by the position of the limb and by opiates. The most relaxed position of the limb is the best. If no tumefaction comes on, emollient applications are not wanted; but if tumefaction, tension, &c. appear, immediately apply emollients. There is a symptomatic fever generally attendant, exclusive of any other circumstances, and this is sometimes attended with such a discharge as to reduce the patient greatly.

“When horses happen to be wounded on the joints, (says Gibson) especially when they break their knees by falling down, or when they cut or over-reach; in all such cases a pledget laid over the wound, spread with common digestive, and bound on with a roller of broad tape or list, will seldom fail of a speedy cure, unless a horse also have the grease, and then the case must be treated as such. If any small abscesses be formed under the skin, these may be opened by incision, in order that no lodgment may be left for the matter. But in the knee, and all the other joints, care must be taken to prevent inflammation, or to abate it if already begun, by the use of proper fomentations or poultices. These effects, however, are more frequent in punctured wounds, that have been caused by thorns or small splinters, than in wounds that are larger. Horses are sometimes in very great pain with punctures on their knees, hocks, or pasterns, and sometimes with contused wounds that have been apparently inconsiderable, and without the least sign of inflammation. But these, though in themselves somewhat dangerous, are generally relieved by the timely use of emollient fomentations and astringent remedies.”

The same writer directs the manner in which fomentations are to be applied to horses. He advises the making so much at a time scalding hot as is necessary for once fomenting, wringing out woollen cloths in the liquor as dry as possible, and applying them five or six times alternately one after another, as often as they begin to cool, which may be done morning and evening, or oftener, till the end is answered. Used in this manner, they give ease, abate inflammation, greatly increase perspiration, and contribute to cleanliness. Gibson asserts that the least appearance of a mild suppuration that is observed on the use of fomentations in wounds of the joints or membranes, indi-

cates that the danger is generally over; for, though the running from wounds in those parts, is usually small in quantity, unless from long continuance, this small discharge in a sound constitutioned horse, he says, gives as speedy a relief as a profuse running from parts of a different texture "I can, therefore, (says he) recommend this method from frequent experience, as the most successful in all contused wounds or punctures upon the joints, or in the tendons, or the coats of the blood vessels, especially when the neck or the plate-vein happens to swell after bleeding, and for rowels, when they have a disposition to gangrene; and in all cases, where a mortification is threatened." He justly reprobates the common method of treating the latter case, which is, "when a substance grows on the neck by festering after bleeding, and want of a sufficient vent for the matter, to put in a caustic of blue vitriol, and sometimes a little corrosive sublimate, or arsenic, which, with the falling out of the eschar, makes a cure only with the loss of the vein."

There yet remains to be considered, a species of wounds requiring a peculiar management, from the variety of extraordinary circumstances that may attend them; we mean *gun-shot* wounds. These, when they take place in horses, require a treatment almost exactly similar to the same kind of wounds in the human subject, since there can exist no other difference than what arises from the stronger powers of restoration in the former.

Gun-shot wounds can be considered in no other light than contused wounds. In those made by a musket or pistol ball, the most immediate considerations are to extract the ball, or any other extraneous body which may have lodged in the wounded part, and to stop the hæmorrhage, if there be an effusion of blood from the rupture of some considerable artery.

It is frequently necessary to enlarge the wound, in order to extract the ball; and if it has gone quite through (provided the situation of the part wounded will admit of its being done with safety), the wound is to be laid freely open through its whole length; by which means, any extraneous body will be more readily removed, and the cure facilitated.

In order to get at the ball, or any other foreign matter, probing is to be used as sparingly as possible; and this must evidently appear to any one who will only consider the nature of the symptoms attendant on penetrating wounds of the

breast or belly, either from a bullet or sharp instrument; the thrusting in a probe to parts under such circumstances, being unavoidably a fresh stab on every repetition of such practice. If probing be necessary, the finger should be preferred as the best and truest probe, where it can be used; where it cannot, a bougie may answer the purpose.

If a ball, or any other foreign body, happens to be lodged near the orifice, or can be perceived by the finger to lie under the skin, though at some distance from the mouth of the wound, we should cut down to it, and take it out; but when it is sunk deep, and lies absolutely beyond the reach of the finger, it must appear evident, upon the least reflection, that thrusting first a long probe in quest of the bullet, and then, as has been practised likewise, a longer pair of forceps, either with or without teeth, into a wound of that kind, though with a sort of certainty to extract it, must either contuse, or irritate and inflame, the parts to a greater degree; and, consequently, do as much, or more, mischief than the ball did at first by forcing its passage such a length of way. And should they, at the same time, lay hold of any considerable artery or nerve along with the ball (which can scarcely fail of being the case), what hurtful consequences would attend such a proceeding! Nor would attempts of this sort be less injurious, in case a bullet should happen to be lodged in the cavity of the belly or breast. Such attempts are the less necessary, because a great number of instances have occurred, where balls have quietly lodged in several parts of the body, till, after many years, they worked themselves a passage towards the surface, and were very easily extracted, and many where balls have been entirely left behind without any ill consequence.

In case the wound be occasioned by a musket or pistol shot, and of course but small, it will be deemed necessary to dilate it without delay, provided the nature of the part will admit of this with safety; for in wounds near a joint, or in very membranous or tendinous parts, the knife, as well as forceps, should be put under some restraint; nor should any more opening be made than what is absolutely requisite for the free discharge of the matter lodged within.

Where the wounded animal has not suffered any great loss of blood (and this is generally the case), it will be advisable

to open a vein immediately, and take from it a large quantity of blood; and to repeat bleeding, as circumstances may require, the second, and even the third, day. Repeated bleedings in the beginning draw after them many advantages; they prevent a good deal of pain and inflammation, lessen any feverish assaults, forward the digestion, and seldom fail to obviate imposthumations, and a long train of complicated symptoms, which are wont, otherwise, to interrupt the cure, miserably harass the poor patient, and too often endanger his life. Even where the feverish symptoms run high, and there is almost a certainty that matter is forming, bleeding, in that state, is very frequently of great advantage.

If it so happen that a gun-shot wound has penetrated any of the large joints, and, in passing through them, fractured the ends of the bones, it will then be found for the most part impossible, let the skill or abilities of the surgeon be ever so great, to preserve both the life and limb of the patient. The reason of this is, that the access of air to the cavity of the joint excites such a violent inflammation as must certainly end in gangrene; and, therefore, for the most part, it will be proper, as soon as possible, to destroy the horse.

Gibson's treatment of gun-shot wounds, though more humane and judicious than was the fashion of his time, will not wholly bear repetition. His advice to pour in spirits of wine, and to introduce *tents* dipped in turpentine, honey, and and tincture of myrrh, would, by no means, be acceptable to the enlightened veterinarian of the present day. The following observations of that respectable writer, however, are rather less at variance with existing opinions.

"Where a ball (says he) has penetrated quite through any part, both orifices must be kept open till the wound is filled up with new flesh, and no bad symptoms remain, as pain, swelling, or inflammation, which, in those gun-shot wounds that enter the bones as well as the flesh, would denote the existence either of extraneous matter or of splinters, which must be removed by gradually enlarging the most convenient orifice.

But in most internal wounds this is unnecessary, because the bullet, or whatever else inflicts the wound, can seldom be brought out by the same way it entered. I have known leaden bullets lie many years in men, especially in the abdomen, without any great pain or danger, and those that have gone deep in the flesh, and beyond reach, make sometimes their way afterwards from places where they could never be expected to appear. Many extraordinary instances of this kind are related in books of surgery, and in the transactions of the learned in several parts of Europe.

I have known bullets pierce through both flesh and bones in men, making a round smooth passage, like an auger-hole, and been as easy of cure as a flesh wound, except when they have penetrated or grazed on the joints. In these cases, horses may be rendered useless, even though the wound be cured. If the bones are splintered the case will always be dangerous, especially if the practitioner has not had experience to know both the time and manner how they are to be treated; for loose splinters should not be suffered to remain where their continuance would endanger gangrene, nor be removed while their removal would create an excess of pain. But in such circumstances emollient poultices are the most likely to prepare them for separation, so as they may at length be brought away with little or no inconvenience, only by the use of a common digestive. If a bullet, a splinter, or any other extraneous body that has been driven a great way downwards from its entrance, can be felt on the outside, a counter opening in that case will be necessary, and this both facilitates the cure, and renders it expeditious. But in all such operations, regard must be had to the situation of the part, to avoid as much as possible, wounding the nerves, tendons, or larger blood vessels."

He observes, very justly, that in dressing gun-shot wounds, it is necessary to avoid all unctuous applications, which encourage the growth of fungous flesh. He advises us to dress the wound with turpentine, mixed with honey or the yolks of eggs, or with honey and turpentine.

"And all statutes, continuing or perpetuating any of the aforesaid statutes or parts thereof, so far as relates to the continuing or perpetuating of the same respectively."

The preamble of the Act then enacts the following provisions, in lieu of those of the repealed statutes.

The second section of the Act enacts, that the word "game" shall include hares, pheasants, partridges, grouse, heath or moor game, black game, and bustards.

By sect. 3, persons killing or taking game, or using any dog, gun, net, or other engine or instrument for the purpose, on Sunday or Christmas-day, shall forfeit any sum not exceeding £5; and persons kil-

ling or taking any partridge between February the 1st and September the 1st; or any pheasant between February the 1st and October the 1st; or any black game, (except in Somerset or Devon, or in the New Forest, Southampton) between December the 10th and August 20th; or in Somerset, Devon, or the New Forest, between December the 10th and September the 1st; or any grouse between December the 10th and August the 12th; or any bustard between March the 1st and September the 1st, shall forfeit for every head of game so killed or taken any sum not exceeding £1, with costs of conviction. And persons putting, or causing to be put, with intent to destroy or injure any game, any poison or poisonous ingredient, on any ground, whether open or enclosed, where game usually resort, or in any highway, shall forfeit any sum not exceeding £10, with costs of conviction.

Section 4 enacts, that if any person, licensed to deal in game by this act, shall buy or sell, or knowingly have in his house, or possession, or controul, any bird of game after the expiration of ten days, (one inclusive and the other exclusive) from the respective days in which it is unlawful to kill or take such birds of game; or if any person, not being licensed to deal in game, shall buy or sell any bird of game after the expiration of ten days (one inclusive and the other exclusive) from the respective days on which it is unlawful to kill or take the same, or shall knowingly have in his house, possession, or controul, any bird of game (except birds of game kept in a mew or breeding place) after the expiration of forty days (one inclusive and the other exclusive) from the respective days on which it is unlawful to kill or take the same, shall forfeit for every head of game so bought or sold, or found in his house, possession, or controul, any sum not exceeding £1, with costs of conviction.

But the 5th section provides, that this Act shall not affect or alter the existing laws respecting certificates for taking or killing any game whatever, or any woodcock, snipe, quail, or landrail, or any conies, but that such annual game certificates shall be taken out as before. And by the 23rd section, if any person shall kill or take any game, or use any dog, gun, net, or other engine or instrument,

for the purpose of searching for or killing or taking game, without a certificate, he shall forfeit for every offence any sum not exceeding £5, with costs of conviction: and such penalty imposed by this Act shall be deemed a cumulative penalty to any penalty to which the person so convicted may be liable under any statute or statutes relating to game certificates.

By section 6, persons obtaining annual game certificates may kill and take game, liable to any trespass committed by them in search or pursuit of game. But no game certificate on which a less duty than £3 13s. 6d. has been paid shall authorize any gamekeeper to kill or take any game, or to use any dog, gun, or net, or other instrument, for the purpose of killing or taking game, except within the limits included in his appointment as gamekeeper; but that if any such gamekeeper shall kill or take game beyond such limits, he may be proceeded against as if he had no certificate.

The 7th section provides, that in all cases where any person shall occupy any land under any lease or agreement made before the passing of this Act, except in the cases hereinafter excepted, the lessor or landlord shall have the right of entering upon such land, or of authorizing any other person or persons who shall have obtained an annual game certificate to enter upon such land for the purpose of killing or taking game thereon; and no person occupying any land under any lease or agreement, either for life or for years, made previously to the passing of this Act, shall have the right to kill or take the game on such land, except where the right of killing the game upon such land has been expressly granted or allowed to such person by such lease or agreement; or except where, upon the original granting or renewal of such lease or agreement, a fine or fines have been taken; or except where, in a case of a term for years, such lease or agreement has been made for a term exceeding twenty-one years.

But the 8th section provides, that nothing in this Act shall authorize any person seized or possessed of, or holding any land, to kill or take the game, or to permit any other person to do so, in any case where by deed, grant, lease, or any written or parol demise or contract, a right of entry upon such land for the purpose of killing or taking the game, has been or shall be reserved or retained by, or given or allowed to any grantor, lessor, land-

lord, or other person whatever; and that nothing in this Act shall defeat or diminish any reservation, exception, covenant, or agreement already contained in any private Act of Parliament, deed, or other writing, relating to the game upon any land; or in any manner prejudice the rights of any lord or owner of any forest chase, or warren, or of any lord of any reputed manor, lordship, or royalty, or of any steward of the crown of any manor, lordship, or royalty appertaining to the king.

And the 9th section provides, that nothing in this Act shall in any way alter or affect any of the king's forest rights, or of any person entitled to any right or privilege under them, or the rights or privileges of any person holding under any grants or purchases from the crown.

The 10th section also provides, that the Act shall not give to any owner of cattle gates, or rights of common, any interest or privilege which he did not possess before the passing of this Act; but the rights and privileges in such wastes or commons shall remain as they did before the passing of this Act.

The 12th section enacts, that where the lessor or landlord has reserved to himself the right of killing game upon any land, he may authorize other persons, having obtained annual game certificates, to pursue and kill game thereon.

But where the right of killing the game upon any land is, by this Act, given to any lessor or landlord, in exclusion of the right of the occupier of such land, or where such exclusive right has been, or shall be, specially reserved by or granted to, or belongs to the lessor, landlord, or any other person than the occupier, then, if the occupier shall pursue, kill, or take any game upon such land, or give permission to any other person so to do, without the authority of the lessor, landlord, or other person having the right of killing game on such land, such occupier shall forfeit, for every head of game so killed or taken, any sum not exceeding £2, with costs of conviction. Sect. 12.

By section 13, lords of manors, &c. may appoint gamekeepers within the same, and authorize them to seize and take all dogs, nets, and other engines and instruments for the killing or taking of game from uncertificated persons within the limits of such manors.

By section 14, lords of manors, &c. may grant such deputations to persons acting as gamekeepers, or employed in any other capacity by other persons.

The 15th section empowers persons possessed of lands in Wales of the clear annual value of £500, whereof he shall be seized in fee or as of freehold, or to which he shall otherwise be beneficially entitled in his own right, to appoint gamekeepers: but the 16th section requires all appointments of gamekeepers to be registered with the clerk of the peace.

The 17th section enacts, that every person who shall have obtained an annual game certificate may sell game to persons licensed to deal in game according to this Act; but that no gamekeeper on whose certificate a less duty than £3 13s 6d has been paid shall sell any game, except on the account and with the written authority of his employer; and that if he does he may be proceeded against as if he had not had a game certificate.

By the 18th section, justices of the peace shall hold special sessions in the present year, between the 15th and the 30th days of October; and in every succeeding year in the month of July, for granting licenses to deal in game to such persons as are householders or keepers of shops or stalls, and not being innkeepers or victuallers, or licensed to sell beer by retail, or being owners, guards, or drivers of mail coaches, or other vehicles employed in the conveyance of the mails of letters, or of stage coaches, stage waggons, vans, or other public conveyances, or being carriers or higglers, or being in the employment of any such persons; which licenses shall empower the persons to whom they are granted to buy game at any place from any person who may lawfully sell game by virtue of this Act; and also to sell the same at one house, shop, or stall only, kept by the licensed person; provided that every person, while so licensed, shall affix to some part of the outside of the front of his house, shop, or stall, and shall there keep a board having thereon his christian and surname, and the words "licensed to deal in game." Licenses granted during the present year to continue in force to July 15, 1832; but such as are granted in any succeeding year, to continue in force for the period of one year next after the granting thereof. But by section 26, innkeepers and tavernkeepers may, without any license, sell game for consumption in their own houses, such game having been procured from some person licensed to deal in game by virtue of this Act. And, by section 21, persons being in partnership, and carrying on their business at one house, shop,

or stall only, require but one license. Licenses to become void on conviction of any offence against this Act. Sect. 22.

Persons licensed to deal in game under this Act must annually, and during the continuance of their license, obtain a certificate on payment of a duty of £2 to the collector or collectors of the assessed taxes, from whom they shall receive a receipt on payment of one shilling; which receipt they shall get exchanged for a certificate under this Act, in like manner as receipts for the duty in respect of killing game are exchanged for game certificates; and if any person, obtaining a license under this Act shall purchase or sell, or otherwise deal in game as a licensed dealer, before he shall obtain a certificate in exchange for such receipt, he shall, for every offence, forfeit £20.

The collectors are to make out lists of persons who have obtained licenses to deal in game, and are to produce the same to all persons making application at seasonable hours to inspect them, on payment of one shilling. Sec. 20.

By sec. 25, if any person not having obtained a game certificate (except such person be licensed to deal in game according to this Act) shall sell, or offer for sale, any game to any person whatever; or if any person authorized to sell game under this act, shall sell or offer for sale any game to any person whatever, except a person licensed to deal in game, he shall forfeit for every head of game so sold or offered for sale, any sum not exceeding £2, with costs of conviction.

And if any person, not being licensed to deal in game according to this Act, shall buy any game from any person whatever, except from a person licensed to deal in game according to this Act, or *bonâ fide* from a person affixing to the outside of the front of his house, shop, or stall, a board purporting to be the board of a person licensed to deal in game, he shall for every head of game so bought forfeit any sum not exceeding £5. with costs of conviction. Sec. 27.

And if any person being licensed to deal in game according to this Act, shall buy or obtain any game from any person not authorized to sell game for want of a game certificate, or for want of a license to deal in game; or if any person, being licensed to deal in game according to this Act, sell or offer for sale any game at his house, shop, or stall, without such board as aforesaid being affixed to some part of the outside

of the front of such house, shop, or stall, at the time of such selling or offering for sale, or shall affix, or cause to be affixed, such board to more than one house, shop, or stall, or shall sell any game at any place other than his house, shop, or stall, where such board shall have been affixed; or if any person not being licensed to deal in game according to this Act shall assume or pretend, by affixing such board, or by exhibiting any certificate, or by any other device or pretence, to be a person licensed to deal in game, he shall for every offence, forfeit £10, with costs. Sec. 28. But the buying and selling of game by persons employed on the behalf of any licensed dealer in game, and acting in the usual course of his employment, and upon the premises where such dealing is carried on, is a lawful buying and selling in cases where the same would have been lawful if transacted by the licensed dealer himself. And licensed dealers may sell any game sent to them to be sold on account of other licensed dealers. Sec. 29.

The 30th sec. reciting, that, as after the commencement of this Act game will become an article which may be legally bought and sold, and that it is therefore just and reasonable to provide that summary means should be provided for protecting it from trespassers; enacts, that any person committing trespasses, by entering or being, in the daytime upon any land, in search or pursuit of game, woodcocks, &c. shall forfeit any sum not exceeding £2. with costs of conviction; and that if any persons, to the number of five or more together, commit any trespass, by entering in the daytime, upon any land in search of game, &c. each of them forfeit not less than £5, with costs of conviction; the leave and license of the occupier of the land so trespassed upon shall not be a sufficient defence in any case where the landlord, lessor, or other person shall have the right of killing game upon such land by virtue of any reservation or otherwise; but that such landlord, &c. shall, for the purpose of prosecuting for each of such two offences, be deemed to be the legal occupier of the land; and that the lord or steward of the crown of any manor, lordship, or royalty, shall be deemed to be the legal occupier of the land of the wastes or commons within such manor, lordship, &c.

The 31st sec. enacts, that if any person shall be found on any land, or upon any of the crown forests, parks, chases, or warrens in the daytime, in search or pur-

suit of game, or woodcocks, snipes, quails, landrails, or conies, any person having the right of killing the game upon such land, by virtue of any reservation or otherwise as is provided for by this Act, or the occupier of the land (whether there shall or shall not be any such right by reservation or otherwise), or any gamekeeper or servant of either of them, or any person authorized by either of them, or for the warden, ranger, verderer, under-keeper, or other officer of such forest, &c. may require the person so found forthwith to quit the land whereon he shall be so found, and also to tell his name and place of abode; and if such person, after being so required, refuse to tell his real name and place of abode; or if he give a description of his place of abode of so general a nature as to be illusory, for the purpose of discovery, the party so requiring his address, or any person acting by his order and in his aid, may apprehend him, and convey him, as soon as conveniently may be before a magistrate; and the offender (whether so apprehended or not, shall forfeit any sum not exceeding £5, with costs of conviction. But no person so apprehended shall, on any pretence whatever, be detained for a longer period than twelve hours from the time of his apprehension until brought before a magistrate; and if he cannot, on account of the absence or distance of the residence of the magistrate, or on account of any other reasonable cause, be brought before a magistrate within such twelve hours, then he shall be discharged; but may, nevertheless, be proceeded against for the offence by summons or warrant, according to the provisions hereinafter mentioned, as if no apprehension had taken place.

By the 32nd sec. if any persons, to the number of five or more together, shall be found upon any land, or in any of the crown forests, parks, chases or warrens, in the day time, in search or pursuit of game, or woodcocks, snipes, quails, landrails, or conies, any of them being armed with a gun, and any of them by violence, intimidation, or menace, preventing, or endeavouring to prevent any person authorized as hereinbefore mentioned from approaching them for the purpose of requiring them, or any of them, to quit the land whereon they shall be so found, or to tell their or his name and place of abode; every person so offending, and every person then and there aiding or abetting such offender, shall forfeit for every offence any sum not exceeding £5.

## APPENDIX.

with costs of conviction; which penalty shall be in addition to and independent of any other penalty to which any such person shall be liable for any offence against this Act.

And by sec. 39, if any person commit any trespass, by entering or being, in the daytime, upon any crown forests, parks, chases, or warrens, in search or pursuit of game, without being first duly authorized, he forfeits any sum not exceeding £2, with costs of conviction.

But the 35th sec. enacts, that the aforesaid provisions against trespassers and persons found on any land shall not extend to any person hunting or coursing upon any lands with hounds or greyhounds, and being in fresh pursuit of any deer, hare, or fox, already started upon any other land; nor to any person *bonâ fide* claiming, and exercising any right or reputed right of free warren or free chase, nor to any gamekeeper lawfully appointed within the limits of any free warren or free chase; nor to any lord or any steward of the crown of any manor, lordship, or royalty; nor to any gamekeeper lawfully appointed by such lord or steward within the limits of any manor, &c.

The 36th section enacts, that when any person shall be found by day or by night upon any land, or in any of the crown forests, parks, chases, or warrens, in search or pursuit of game, and then and there having in his possession any game which shall appear to have been recently killed, any person having a right of killing the game upon such land, by virtue of any reservation or otherwise, as before provided for, or the occupier of the land (whether there shall or shall not be such right by reservation or otherwise), or any gamekeeper or servant of either of them, or any officer, as aforesaid of any forest,

&c. or any person acting by the order and in aid of any of the said several persons, may demand from the person so found, the game which may be in his possession; and in case he shall not immediately deliver up the same, may seize and take it from him, for the use of the person entitled to it.

The 34th sec. defines what shall be deemed day-time, for the purposes of the act; namely, from the beginning of the last hour before sunrise to the expiration of the first hour after sunset.

The 24th sec. provides, that if any person not having the right of killing game upon any land, nor having permission from the person having the right, wilfully take out of the nest or destroy in the nest upon the land the eggs of any bird of game, or of any swan, wild duck, teal, or widgeon, or knowingly have in his house, shop, possession, or controul any eggs so taken, he shall forfeit for every egg so taken or destroyed, or found in his possession, any sum not exceeding 5s. with costs of conviction.

The remaining sections of the Act (viz. from 37 to 47 inclusive) provide for the application of the penalties for offences against the Act, the time of the payment thereof, and the periods of imprisonment for non-payment; the form of conviction; the power of summoning witnesses; the time for proceedings, and the mode of enforcing appearance; the appeal, and the venue and proceedings. The 46th section provides, that the Act shall not preclude actions for trespass; but that, where any proceedings have been instituted under this Act in respect of any trespass, no action at law shall be maintainable for the same trespass. And the 48th section, that the Act shall not extend to Scotland or Ireland.
